favour of either. Philosophers distinguish two kinds of doubt,—provisional and definitive. Provisional doubt is a voluntary suspension of our judgment for a doubt is a voluntary suspension of our judgment of a time, in order to come to a more clear and sure con-clusion. Definitive doubt is scepticism. We doubt through blindness, or passion, or malice; through fancy, or from a wish to doubt; but we doubt also from prudence and from mistrust, from wisdom and from prudence and from mistrust, from wisdom and through penetration of mind. A preliminary doubt is the fundamental condition of philosophy. We begin, in order that we may not end with doubt. This was first established as a rule in philosophic inquiry by Descartes, who tells us that he began by doubting everything, discharging his mind of all preconceived ideas, and admitting none as clear and true until he had anticated them for pricorous commission. had subjected them to a rigorous examination.

blet"

DOUBLET, dub'-let (Ang. Nor.), a tightly-fitting coat or jacket, closely resem-bling the jerkin. Itreached a little below the waist-belt; and the sleeves, al-

though generally fastened

on to the body of the garment, were sometimes detached, and tied on at the shoulder. The name "dou-

dress are frequent in the old dramatists; thus Shir-ley, in his "Bird in a Cage" (A.D. 1633), says,— "Every morning does this fellow put himself upon the racke with putting on his apparel, and manfully endures his taylor when

those species of which many nests are built close to gether on the same trees, and dove to those which are gener on the same rees, and dove to those when are solitary in their nidification; but this distinction is quite unsuitable to the European species and contrary to British usage. (See PIOEON.) DOVE, SYMBOL OF THE.—The Holy Ghost having

descended upon Christ at his baptism in the form of a dove, that bird is generally employed as a symbol of the Spirit in religious art. It is also used as an emblam of peace, when it bears an olive-branch in its mouth, doubtless referring to the return of the dove to the ark. When used as an emblem of purity by the ancient painters, it was usually represented white, ancient painters, it was usually represented white, with red claws and beak, and sometimes with a golden aimbur round the head. Dying saints and martyrs of the British Association, is the one which was used 687

are frequently represented with a dove flying from their mouths; in these cases it is a symbol of the soul purified by suffering. In some stained windows, the seven gifts of the Holy Spirit are symbolized by a dove, seven gins of the Hoy spirit are symbologically wavelength, which proceed seven rays, terminating in seven stars. When used as a symbol of the Church of Christ, the dove is represented with six wings,—two at the head, two at the shoulders, and two at the feet. The figure of a dove is often to be seen in English characters at the present day one the operator of forts.

churches at the present day over the covers of fonts.

Doverant, in Carpentry and Joining, the name given
to a peculiar method of connecting two pieces of timber together. The end of one piece is cut into one or more projections, resembling the fan-like form of a bird's tail, which are fitted into a hollow or hollows of eracity the same shape cut out of the end of another pieceto receive them. It is used for joining flat boards, and in scarfing beams together, as well as for joining timbers end to end or at right angles to each other, and the ends of the sides of boxes and drawers.

Downgen, dow-d-jer (Fr. douarriere), denotes, properly, a widow with a dower, but commonly the title is only applied to the widows of persons of high rank, and

only applied to the wholes of persons of high rank, and is used to distinguish them from the wives of their husbands' heirs, who have the same name and title.

Dower, dow'-er (Welsh, dawd), that portion of a husband's lands, tenements, &c., to which a wife is entitled for her life upon the death of her husband.

Dower, dow'-re (Lat. dos, a gits), though often confounded with dower, has quite a different meaning, being the marriage portion brought by a wife to her husband.

husband. Doxology, doks-ol'-o-je (Gr. doxa, glory, and logos, a discourse), denotes a form of praise, or giving glory to God; as in the concluding paragraph of the Lord Z Prayer,—"Thine is the kingdom, and the power, and the glory, for ever;" or the Hymn of the Angels (Luke ii. 14),—"Glory to God in the highest, and on earth peace, good will to all men." Two hymns used in the early Christian church were known as the greater and leaser doxology. The greater develops was simply and lesser doxology. The greater doxology was simply an expansion to the angelic hymn, and is now generally known by that name; it is sung in the Roman Catholic church at the celebration of the Lord's Supper and at matins. The lesser doxology is the ordinary doxology, "Glory be to the Father, and to the Son," &c., repeated at the end of each psain in the service of the Church of England.

DRACEMA, draits not from Gr. drakaina, a female dragou, the inspissated juice becoming a powder like dragou's blood), in Bot., a gen. of plants belonging to the ust. ord. Likacea. The most remarkable species is D. Draco, the dragon-tree of Teneriffe, which drains a drain of the most remarkable species is D. Draco, the dragon-tree of Teneriffe, which drains a drain of the dragon tree of the most remarkable species is D. Draco, the dragon-tree of the dragonwhich attains a great size, and, unlike the majority of monocotyledonous trees, has forked branches. This plant yields a red resin, resembling dragon's blood, but it is not known in commerce. D. terminalis, the tiplant, a native of the Sandwich Islands, has sturched.

panni, a native of the Sandwich Issaud, as suredy roots, which are baked and eaten by the islanders; it juice is used for making a fermented beverage, and its leaves are employed as fodder for cattle.

DRACHE, DRACHEMA, or DRAM, drüm (Gr. drachme), a silver coin of ancient Greece, used as the unit of the money system. Since the year 1833 the anti of the money system of modern Greece has also been called draches, and is early to the table. money system of modern Greece has also been called drachma, and is equal to about \$3d\$. Amongst the sucients the value of the drachma was nearly equal to a French franc, or \$3d\$ in English money. It differed according to the value of specie, but was always calculated as the 100th part of the mina, which was generally worth about £4 sterling. There were also coins valued at two, three, and four \_rachmas. As a weight the drachma was considered also equal to the 100th part of a mina, or about \$\frac{1}{2}\text{ or quite to the 100th part of a mina, or about \$\frac{1}{2}\text{ or quite to the 100th part of a mina, or about \$\frac{1}{2}\text{ or quite to the 273} grains troy, and the apothecaries', which is equivalent to \$273\$ grains troy and the apothecaries', which is equivalent to \$60\$ grains troy. Dacco, drai-ko (Gr. drakon, Lat draco, a dragon), a constellation in the northern hemisphere, between Ursa Minor, Cepheus, Cygnus, and Hercules. The largest star in this constellation is of the second magnitude. This star, known as 7 Draconis, and numbered

DRAFT, OF DRAUGHT, draft (from Sax. draffas, to draw), is an order from one person to another, directing the payment of money either to the drawer or to a third party. The term is also applied to the first or rough copy of a legal or formal document. When this draft is corrected and finally adjusted, it serves as the material for a fair copy. Proof-sheets and MSS, may be called the drafts of printed works. In Mil., the

be called the drafts of printed works. In Mil., the selecting and detaching of soldiers from a company, regiment, &c., to form other companies, or to proceed upon certain duties, is termed drafting.

DRAG, drdg (Ang.-Sax.), a mechanical arrangement, by which the speed of a vehicle can be decreased by stopping or slackening the rotation of one or more of stopping or alackening the rotation of one or more of the wheels. The original drag was a very primitive arrangement, and was generally called the shoe or skid; it consisted of a hollow piece of iron, not unlike a shoe in shape, which fitted the tire of one of the hind wheels. It was attached to the bottom of the carriage by a chain, and when applied was put under one of the hind wheels; by this means, acting as a sort of wedge, it prevented the wheel from going round, and thus retarded the velocity of the vehicle. The invention of the patent drag was a great improvement upon tion of the patent drag was a great improvement upon this clumsy mechanism. By means of the patent drag a sort of skid is pressed against one of the sides of a a sort or skid is pressed against one of the sides of a wheel, effecting all the stoppage required, with the advantage that the whole can be regulated by the driver, without stopping or getting down, by means of a handle connected with a series of rods and levers. In the case of the shoe-drag, the stoppage of the carriage every time it was put on or taken off was absolutely received. lutely necessary. The use of the drag is to keep the vehicle from pressing too hard upon the horses when going down hill at their ordinary puce. Powerful drags, which not in a similar manner to that described, are used for stopping or decreasing the speed of rail-

drags, which not in a similar manner to that described, are used for stopping, or decreasing the apeed of railway trains: they are called breaks.

Dragoman, drag-o-man (Turk: trukeman), the term applied, in Turkey, to all interpreters or foreign guides. The diplomatic dragomen, however, are very important personages, and serve as a means of communication between the officers of the Ottoman government and the ambassadors of other European nations. They are allowed several important privileges, not the least of which is, that they and their families are not considered to be under Turkish law, but under the jurisdiction of the country by whose embassy they are employed. As the laws of Turkey are very severe and summarily carried out, this privilege is much valued. The diplomatic dragomen are seldom pure natives, but mostly Italians, descended from Geneese or Venetian merchants. The occupation of the ordinary Turkish law, the dragoman is exactly similar to that of the French commissionnaire and the Italian cicerone. Dragomen of this description are provided at many of the hotels in Constantinople, and other cities throughout Turkey.

Dragon, drag-on (Gr. drakon, Fr. dragon), a term

DEAGON, drag'-on (Gr. drakon, Fr. dragon), a term

applied in modern Nat. Hist. to certain kinds of in fine summer weather huwking about over the surface saurian teptiles. Some of these (the genus Drace of of ponds and rivers in search of insect prey. Their

Linnæus) are furnished with a broad membranous lobe on each side. This is supported by the six first false ribs, which are extended straight outwards from the vertebral column. By the movement of these bones, the reptile is enabled to stretch its broad lateral memthe reptile is enabled to stretch its broad lateral mem-brane, which thus forms a sort of parachute, to sup-port it in its long leaps from branch to branch. They, however, are quite destitute of any power to strike the sir; so that their flight is nothing but a floating through space. As a rule, the species is harmless; there is, however, one, inhabiting the marshy plains of Guiann, and called the flying dragon, that bites severely if it should be handled. This creature has a long com-

should be handled. This creature has a long compressed tail, the back and tail created, and the tongue forked, like that of a serpent: it sometimes attains a length of six feet. "Both its flesh and eggs are eaten.

Dagon, in Myth. Hist.—In nearly every country, and at all times, there have been legends concerning the existence of a huge monster, which went about devouring and devastating all before it. This monster, which we have the concerning and devastating all before it. This monster, a concerning the supposed to be a suppo or dragon as it is generally called, is supposed to be or dragon as it is generally called, is supposed to be the symbolical representative of arrogant power and cruelty, whose sole object is to oppose order and pro-gress. Although it is probable, as Brand save, that "the dragon is one of those shapes which fear has created to itself," nevertheless, from the generality of the legends concerning this winged saurian, it is pos-sible that the existence of some species of the pterodactyl, in very remote times, may have originated the dastyl, in very remote times, may have originated the superstition. However this may have been, it is certain that this mythical animal, in all ages, has been looked upon as a minister of evil, the destruction of which was considered one of the grandest objects of human energy. The task was usually allotted to gods and herces. Apollo killed the Python, and Perseus slew the dragon, and saved Andromeda. Hercules, as the ideal of physical power, is also represented as a dragon-slayer. From poetry the legend of the dragon passed into art, and the Greeks and the Romans bore it as an emblem on their shields and helmets. In the Nib'tunega Lied, in later times, Slegfried is repre-Nibriumen Lied, in later times, Siegfried is represented as killing a dragon; and in the epic of Beowolf, the two contests of the hero, first with the monster Grendel, and afterwards with the dragon, form the principal incidents of the poem. Among the Scandinaviaus, Thor was described as a dragon-slayer. Among the Teutonic tribes the practice of bearing the dragon as an emblem on their shields and banuers was common, and they introduced the practice very carly into England. Among the Celts the dragon was con-sidered the emblem of sovereignty, and as such was borne on the helmet of the monarch. In the Middle Ages, in religious paintings, the dragon was looked upon as the representative of sin. Saints and martyrs are frequently depicted trampling a dragon under foot. It is also used with this signification in the figure of St. George and the Dragon. Sometimes it has been used as a symbol of heresy. A body of men in Hun-gary, who enrolled themselves in order to crush John Huss and his followers, called themselves Knights of the Order of the Dragon. The figure of the dragon is much used in heraldry; and when an animal, such as a lion or tiger, is represented with its own head but with a dragon's wings and tail, it is said to be dragonné. Fiery dragons were meteors of which there are many old records. The fear of the spectators bestowed the forms of dragons on the phenomena which they

DEAGONET (Callionymus), a fish of the Gobioida fam., inhabiting the Mediterranean and Northern seas. They are remarkable for having the gill-opening reduced to a small hole on each side of the nape, and the wentral fins placed under the threat, separate and larger than the pectorals. The eyes are placed on the top of the head, looking upwards; the skin smooth and scaleless. The colours of the fish are yellow, blue, scaless. The colours of the fish are yellow, blue, and white, making a beautiful appearance. There are three or four species; but that known with us as the genmeous dragonet (Callionymus), and, by the Scotch, gowdie, is by far the most beautiful. All the species are about twelve inches long.

Dragon-fly (Libellula), a Linawan gen. of near-pterous insects, common in England, and to be seen in fine summer weather hawking about over the surface

vulgar English name is "horse-stinger," which is no less inappropriate than ugly, as the insect possesses no means of analying either horses or any other of the larger animals. They rival the butterflies in their lives and like the larger hand. means of annoying either horses or any other of the larger animals. They rival the butterflies in their hues, and, like them, love to bask in the sunshine. They are, however, not nearly so harmless in their mode of living, sud, instead of the nectar of flowers, prey on insects. They have strong horny mandibles and maxille, covered by the labrum and labium; their tarsi are three-pointed; their wings are equal; the posterior extremity of the abdomen is furnished with hooks or peculiar appendages. Their ferocity is so ungovernable, that when taken and imprisoned, they have been known to devour their own bodies. The have been known to devour their own bodies. great dragon-fly (Alshna grandis) is about four inches long, and the largest of the British species. It has been seen to dart upon a large cabbage butterfly, and to bite off the wings and devour the entire body in less than a minute. In the larva state, the Libellulide than a minute. In the larva state, the Libellulides live entirely in the water, engaged in unceasing strife with other insects, for whose capture and destruction it possesses ample means, through a singular contri-vance of its lower lip. This consists of two principal pieces, one of which is articulated to the head, whilst the second is attached to its extremity. At the spex of this second piece, two jaw-like organs are articulated. In repose this lip is folded beneath the head, but can be immediately extended to a considerable distance in front of the head, so as to seize any minute insects or small fishes that may pass before it. The respiration of the large of some of these insects is singularly contrived. They are provided with the means of drawing water into their bodies to supply air for respiration, and expél it again by the same oriflee at the extremity of the abdomen, with such force, that they thus propel themselves through the water, whilst their large terms of the The hostest the extremities. they thus proper themselves through the water, whilst their legs are at rest. The hooks at the extremity of the abdomen of the dragon-fly render the creature essential service at the period of transformation. Crawling out of the water, it attaches itself by these hooks to a stick or rush, and struggles out of the pupa-At first its body is quite soft and moist, and the wings folded up into a small compass. In a few hours, however, the wings are capable of expansion, and the body assumes a proper consistency. Dragon-flies abound most in warm climates, but are met with in very northern regions.

DRAGON-TREE. (See DRACENA.)

DRAGON'S BLOOD. (See CALAMUS, PTRROCARAUS.) DRAGOON, drug-oon' (Fr. dragon, from Lat. draco, DRAGOON, drag-oon' (Fr. dragon, from Lat. draco, a serpent with wings and claws, supposed to be able to emit flames from the mouth), a mounted soldier, so called from the weapon with which the horsemen raised about 1600, by the Mareschal de Brissac, were armed; be-cause the muzzle was shaped like the extended jaws of a dragon. It is the common term for a cavalry soldier in the British service. (See CAVALEY.)

DRAIN, drain (Sax. drehnigean), the name applied

to any channel constructed underground for the pur pose of carrying off surplus water and refuse mat-ter from houses, fields, &c. When drains are open and are merely channels out along the surface of the ground, or by the sides of streets and roads, they are called ditches and gutters; when they are of great size, for the purpose of carrying off the refuse of a town, they are called sewers. Drains that lie underground may be formed of pipes of clay or carthenware, or of low walls of brick or stone, raised on a bottom formed of broad flat stones, and covered in with the same. These are, however, more liable to become choked by the roots of trees and shrubs growing into them than those which are formed of pipes. Circular drains of brickwork are called barrel drains.

DEAINING, or DRAFNAGE, the art by which surplus water may be carried off from swampy districts and stiff clay soil, as well as other land in which the excess stiff clay soil, as well as outer than an unity of water is prejudicial to vegetation. It may be applied to low districts containing thousands of acres, or to sincle fields of comparatively small extent. In the

be cut in the direction of the slope of the field, which is the direction in which it is pleughed from top to bottom. The trenches for drains are out with spades of different widths, the upper part of the trench being taken out with the widest, and a very narrow one, and the terminal termin called a bottoming-tool, being used to form the bottom of the trench, so that the vertical section of a trench cut for the formation of a drain exactly resembles that cut for the formation of a drain exactly resembles that of a flower-pot. The bottom of each trench was at first filled with rough stones only, about 2 or 3 inches in diameter, and a thick layer of soil was thrown over them; but subsequently, drain-tiles and pipes were used without the addition of any stones above them, as the drains were found to be less liable to obstruction. tion when the whole of the trench above the pipes was filled in with earth. The tile-and-shoe drain was introduced when the practice of filling the trench with atones was first abandoned: this consisted of a flut tile, or shoe, which was laid at the bottom of the trench, and on which another tile, arched in form, was placed, which was of the same length as the shoe was placen, when was of the same length as the shoe on which it stood. But these have been superseded by the cylindrical drain-pipes, which are made in all sizes, from 12 to 24 inches in length and from 1 to 6 inches in diameter. Pipes about 2 inches in diameter are commonly used for small drains, and the larger sizes, from 4 to 6 inches in diameter, for sub-main drains. In loose or peaty soils the pipes should be connected by collars, but this is not required in ordi-nary soils. The depth and width of the trench at the nary soils. The depth and width of the trench at the bottom of which the drain is to be placed must also be regulated, in a great measure, by the nature of the soil; but it should in no case be less than 2 feet or more than 6 feet below the surface. When the drains are than 6 feet below the surface. When the drains are about 3 feet deep, and less than this, they should be placed about 25 or 30 feet apart; but when they are deeper than 3 feet, they should be placed apart, at distances varying from 50 to 70 feet. It has been calculated that the cost of drainage per acre varies from £2. 10s. to £5. The cost of pipes per thousand is as follows:—1 inch in diameter, \$s. 6d.; 1\frac{1}{2}, 6s.; 1\frac{1}{4}, 6s.; 1\fr is obtained, which readily absorbs moisture in time of drought; heavier crops are obtained, which ripen earlier, as the seed can be sown sooner on drained than on undrained soil; mosses, rushes, and coarse sour grass are entirely removed in course of time, and the air is no longer tainted with the exhalations that rise from marshy land; the soil also can be worked sooner after a heavy fall of rain than it could have been when it was in an undrained state. The drainage of exten-sive districts comes within the province of the civil sive districts comes within the province of the civil engineer. Among the principal tracts of country that have been reclaimed and made available for pasturage and tillage by draining, may be mentioned, the Bog of Allen, in Ireland; Chat Moss, in Lancashire; and the Pontine marshes, near Rome. Immense works of this nature have been carried out in Holland, and in the fen districts of Cambridgeshire and Lincolnshire, near the Wash, which are drained by what is called the the Wash, which are drained by what is called the "Bedford Level," under the control of the Bedford Level corporation. In the cases that have just been mentioned, the surface of the land reclaimed lies below the level of the sea, and the water that is continually collecting from rain and other causes is discharged through self-acting floodgates, or has to be lifted, by wheels or Archimedean screws, over the embankments that have been constructed to prevent the encrocliments of the water. These wheels and pumps are worked by steam power, and, in Holland, sometimes by means of windmills. Constant care and watchfulness is required to see that the embankments, sluices, floodgates, &., are always in perfect order and repair. On May 4th, 1862, the Middle Level sluice, through which the waters of the Middle Level drain are discharged, that waters of the Middle Level drain are discharged, that runs through the fens for eleven miles, suddenly blew up, as it is called, having been undermined by the waters of the German Ocean. The since had evinced unmistakable signs of decay for a considerable period. When it first burst, about 10,000 acres of fertile ground, rich and smiling with the accumulated industry of years, were submerged in a few hours, and the sluice, that had been erected at a cost of 240,000, was reneared activation was a power of the submerged of the submerged to the submerged of the su to low districts containing thousands of acres, or to up, as it is called, naving been undermitted to the single fields of comparatively small extent. In the waters of the German Ocean. The sluice had evinced latter case it is chiefly applied to render stiff and tenacious clay soils friable, fertile, and uroductive; and, indeed, it is now found that no land of this description can possibly be brought into proper cultivation years, were submerged in a few hours, and the sluice, without having recourse to this system for its ambiout that had been erected at a cost of £40,000, was rentation. It is considered better that all drains should on, destroying crops and cattle, and damaging homesteads and farm-buildings, until thousands of acres, in addition to what had been covered by the first rush of the sea through the broken sluice, were hidden under water. The efforts of the most skilful engineers were powerless for many weeks to put a stop to the work of destruction that was going on in the Marshland fens; and it was not until the end of the following month that the ingress of the waters was checked. This disaster was followed by the destruction of the Marshland Smeeth sluice, a drain entering the Ouse about 300 yards to the north of the Middle Level sluice, on the evening of Oct. 4th. This happened in consequence of the extra pressure on the embankment and works, owing to the discharge of a quantity of water from the land that had been submerged in May, through this and an adjoining drain, called the Marshland sower. The rush of water had undermined and scoursed away the earth behind the flank walls of the sluice, although every precaution had been taken to strengthen the embankment on either side. In consequence of the destruction of the sluice, which gave signs of breaking up only ten minutes before the catastrophe happened, a great part of the country which had been reclaimed and brought into cultivation since the bursting of the Middle Level banks in May, was again flooded, and the struggle to force back the encreaching waters of the North Sea had to be commenced anew.

Drain-trap.—When a drain has been constructed, it is desirable to prevent the escape of any mephitic gas from the drain itself, generated by the decomposition of its contents, as well as the entrance of sand and any solid matter into the water-course, which would form an accumulation and choke the drain. To obviate this a small square pit is made at the head of the drain, the bettom of which is below the level of the mouth of the pipe. The pit is covered by a graing or perforated plate, to the centre of which an iron cup is attached, which fits over the top of the pipe, and has its lip below the surface of the water in the pit. The water between the mouth of the pipe and the surrounding wall of the cup acts as a barrier to prevent the escape of any foul air from the pipe. This is the common bell-trap, which is liable to get out of order in consequence of the ease with which he loose grating and cup may be removed. The most efficient drain-trap that can be used, which has received the approbation of architects, builders, and medical men, is the new patent sink-trap, invented by Messrs. Tye & Andrew, Brixton Road, Londou. It effectually prevents the escape of all noxious vapour, and when the trap is once fixed, the grating cannot be removed, which prevents the entrance of any solid substance into the drain. Besides the fixed grating, other points of importance which render the trap infinitely superior to all others, are the column of water which it opposes to the escape of any vapour that may be generated in the drain; and the serve boss, which allows a forcing-pump to be attached to the trap, which will remove any other communicating with it from a stable or elsewhere, and thus obviate the unpleasant alternative of opening the drain, to the detriment of the pavement, turf, beds, or garden walks under which it passes, whenever a stoppage may occur.

Drama, drai-ma (from the Gr. drama, action), a poem or piece composed for the stage; a composition in dialogue, in which the action is recited and represented, and not related. The love of imitation is inherent in human nature; and the first evidence of intellect given by a child is his assumption of the manner and bearing of some other person. As with individuals, so with nations; and almost every socient and modern civilized people have cultivated dramatic representation in some form. The Hindoos and the Chinese have a rich store of theatrical works; and in China the love of dramatic exhibition is a perfect rage. According to Aristotle, the Attic drama arose from the recitations of the leaders of the Dilbyrambus. The origin of the Greeian drama is said to have been the origies of shepherds and pessants in their solemnization of the rices of Bacchus, when the secrifice of a goat was followed by dances and a sort of masquerade, in which they personsted fauns and satyrs. In place of

masks, they stained their faces with the less of wine; and to the music which formed the principal part of this wild festivity, was added the recitation of an indi-vidual performer, who entertained the audience by his own single and unsided exertions. Thespis was the first to shape a regular entertainment out of these rude first to shape a regular entertainment out of these rude materials, in which effort he is said to have been assisted by one Susarion. The actors were separated from the audieuce, and placed upon a cart, or elevated platform made of boards laid upon trestles. The date of this first improvement was about 440 or 450 years before the Christian era. Eschylus was the first who converted monologue and soliloquy into action and dislower. He introduced upon the boards more and dialogue. He introduced upon the boards more than one actor at the same time, and relieved the declamation of the Thespian orator by the musical performance of a chorus: he also introduced scenery. A theatre, first of wood, afterwards of stone, accommodated a number of regular and attentive specta-tors; and the principal actors dressed in personal tors; and the principal actors dressed in personal diagniess suitable to the characters personated. They also were masks painted to represent the personal whom they performed. The mouths of these masks were shaped like the end of a trumpet, which, though it aided the actor's voice in filling the enormous area of the theatre, must have had a ludicrous appearance. The cothurnus, or buskin, added to the contract is highly the geograph distance between the actor's height; the enormous distance between the eyes of the auditors and the actors considerably lessening the apparent absurdities of the mask and buskin. Great trouble and expense were bestowed upon costume. When a Grecian actor personated a hero or a god, he concealed his face, increased his height, and wore a dress and mask exactly resembling the popular idea of the personage to be portrayed. The theatres were of enormous size, and built in the shape of a horse-shoe. The audience were placed on seats ele-vated one above another in gradation. The stage, which was on a level with the lowest row of seats, was placed at the flat end of the building. The space in the centre of the theatre, called in the present day the pit, was called the orchestra, and was occasionally occupied by the chorus. Æschylus having regulated Sophocles, Euripides, and other dramatiets, improved Sophoeles, Euripiaces, and other carmatices, improved an amusement to which the art-loving Greeks became passionately attached. During the performance of a play written by Hegemon, news was brought of the total defeat of the Grecian army before Syracuse. Among the auditors were relations of those who had fallen, and hardly one spectator had not, in addition to a patriotic grief, to mourn the loss of a friend or relative. They did not quit the theatre, but, spreading their mantles before their faces, ordered the representation to proceed, and, thus veiled, remained till its conclusior. The admission to these ancient theatres was at first one drackma; but Pericles caused the price to be lowered to two oboli. In their personations, the Grecian actors aimed at gravity of movement and declamatory grace, rather than the rapidity and vivacity of passion. They held a high rank in the republic, and popularity carried with it a rich recompense. The old Grecian comedy will be best described as the exact opposite and antithesis to their tragedy; for as in tragedy, doities, Titans, and departed heroes declaimed in sublime sentences, so, in comedy, the whole plan of a piece often turned upon these same sublime per-sonages, who were brought upon the stage for the mere purpose of ridicule. In fact, the Grecian comedy was a burlesque in the most modern sense of the word, in which Bacchus was represented as a coward, and Her-cules as a glutton. Aristophanes, the author of this kind of entertainment best known to us, was not the originator of the Grecian comedy: he had many predecessors, Magnes, Cratinus, Crates, Eupolis, and others. After ridiculing the Olympian deities, a species of mythological irreverence which the Athenians heartily enjoyed, he made the stage a vehicle for attack on public men, and, among others, Socrates and Cleon, a demagogue of great influence. Decrees were passed to protect the citizens against scurrilous dramatic libels, and finally comedy was prescribed. An actor named Anaxander was punished capitally for parodying a line of Euripides so as to convert it into an attack upon the government. He was starved to death,—a fate that has since, not uncommonly, fallen to

#### Drama

the lot of both actors and dramatists. Aristophanes, who found that personality and invective were no longer tolerated, barbad the arrow of his wit at the accidents and absurdities of domestic life, in which walk of satire he was successfully followed by Menander and others. This new mine of satire was called by the aucients the New Comedy; and it was about this time that dramatic representations began to be divided by intervals of cessation, or acts, the use of the chorus being discontinued with the old comedy. If the dramas of Plautus and Terence do not present any great variety of character, it must be remembered that in works professing to be a picture of actual manners, comic writers could not, in a country where women led a life of seclusion, write for representation any female characters but those of mothers, maid-servants, and courtesans: thus the plot of a piece often turned upon the passion of a lover for a young woman, who was not brought upon the stage once during the play. Despite these disadvantages, the new comedy of the Greeks often conveyed a knowledge of deep truths and subtle feeling. In closing these brief remarks upon the Greek stage, it must be mentioned that the apostle Paul has

quoted from the Grecian drama.

The Romans had a sort of rude histrionic representation of their own. Their oldest spoken plays were ation of their own. Their oldest spoken plays were borrowed from the Osei, the indigenous inhabitants of Italy, and were called Fabula Ataliana. The performance consisted of satirical couplets, which were declaimed during the intervals of the games, and characters of fabulous antiquity were usually person-According to Livy, 361 years before the birth of Christ, during the rage of a great pestilence, in order to propitiate the deities, the Romans introduced a regular dramatic entertainment. Their plays, how-ever, notwithstanding the assumption of the mask and buskin as a regular profession, were rude in structure, until Livius Andronicus, who was by birth a Grecian, led the way to improvement by transplanting his native stage to Rome. The works of the Roman tragic authors, with the exception of those of Seneca, have not reached our time, though, singularly enough, we are compelled to judge of the new school of Greek comedy through the medium of Latin translations; indeed the Romans had two species of comedy,-the Palliata, in which the scene and dress were Grecian, and the Togata, in which they were Roman. It is presumed that as Roseius Gallus is mentioned by Cicero as wearing a mask upon the stage, in order to concesi an obliquity of vision, that other actors of his day played with their faces uncovered. The Romans, to quote the words of St. Augustine, "accounted the art of stage-playing infamous, and ordained that stageplayers should not only want the honour of other citizens, but also be disfranchised and thrust out of their tribe." This feeling was doubtless engendered by the fact of the Romans confounding the dramatic art with the games of the circus and amplitheatre, in which gladiators and slaves performed. Notwithstanding a denunciatory edict of the prætor, many actors rose to great wealth and high esteem in Rome. Roseius was the friend of Piso, Sylla, and Cicero; and Paris, who was afterwards put to death by Domition out of jealousy, exercised an arbitrary authority over dra-matic authors. Critics formed a code of laws for the guidance and regulation of the poet, of which Aristotle and Horace expressed their approval. The ancient and Horace expressed their approval. The ancient dramatic art expired with pagan Rome, and in its first age Christianity was inimical to the theatre. Any person connected with the dramatic art was not allowed baptism. The connection of the ancient theatre with heathen superstition, and the profligacy of some of the entertainments exhibited, offended the primitive church. With the extinction of literature and art, every trace of dramatic composition or preforments. every trace of dramatic composition or performance was for many conturies lost. The modern drama, like was for many conturies lost. The modern drama, like the ancient, had its foundation in religion, with this difference, that in place of the worship of Bacchus, difference, that in place of the worship of Bacenus, miracle-plays and mysteries were produced. The first speaking sacred drama is said to have been "Della Passione di nostro Signor Giesu Christi," by Giuliano Dati, bishop of San Leo, in 1455; and it was in Italy, the country in which the tragic art expired, that it revived in a different and purer form; but considerable uncertainty exists on this point; for the French claim

## Drama

the performance of a pastoral entitled "Un Jen" as early as the 13th century. The Chester Mysteries, the earliest plays acted publicly in England, were performed from 1268 to 1276. The meaning attached to the word "inystery" may be gleaned from the quotation of two of the verses of the prodamation or prologue to the famous Chester Mysteries or Whitaun Plays. The "moonke" mentioned is one Done Rondail, of Chester abbey, the deviser of the Mysteries:

This moonke, moonke-like in Scriptures well seene, In storyes travelled with the best sorte; In pagentes set fourin, apparently to all eyne, The Olde and Newe Testament with livelye comforte; Intermynglinge therewith, onely to make sporte, Some things not warranted by any writt, Which, to glad the hearers, he woulde men to take with

Now, you worshippfull Tanners, that of custome olde

The fall of Lucifer did set out,

Some writers awarrante your matter; therefore be boulde,

Lustily to playe the same to all the rowtte; And yf any thereof stande in any doubte, Your author his author hath, your shewe let bee, Good speech, fyne players, with apparill comelye.

Rude parodies of sacred history being inconsistent with the purity of the Christian religion, the Mysteries were succeeded by the Moralities, a sort of performance that bore considerable resemblance to the Old Comedy of the ancients, as they were founded upon allegorical subjects, almost always bore allusion to the events of the day, and abounded with strong and biting satire. Upon the revival of letters, Latin plays were composed by the learned in avowed imitation of the productions of anoient Greece and Rome; but the general public, to whom the classic drama was as a scaled book, showed a strong partiality to a new sort of representation, a union, or, rather, compound, of tragedy and comedy, which was called History or Historical drama. These generally told the exploits of a king from his manhood to his death, with such points of history as were the most marked and striking of his reign. These dramatic chronicles were so popular in England that hardly a single subject upon which Shakepere wrote had not been appropriated by his predecessors; the majority of his historical plays were therefore altered by his in the propulse.

majority of his historical plays were therefore altered by him from the plan of old dramatic chronicles.

The Romatic drama, which followed the historical, was founded upon legends, poems, and popular fictitions narratives. In Spain, the land of chivalry and romance, Lopez de Vega and Calderon, disregarding or despising the restrictions of the classic drama, inaugurated a new school. Their heroes, the exact reverse of the passionate sensual demigods of the ancient drama, were virtuous, self-sacrificing, brave, true, and loyal. Action and bustle took the plane of tedious elaboration of sentiment and thought; the passion of love was sublimated into a high, generous, and romantic feeling; and the introduction of a clown, who made extemporaneous jests both to actors and to audience, gave great pleasure to spectators, who were unwilling that the actors should entirely ignore their presence, and liked a chorus, though comprehended in one person, to explain and criti-isse the action of a play during its progress. In England the romantic drama was welcomed with ardour. In Italy the taste for the ancient and classical school of drama was so rooted that romantic dramas, histories, and tragi-comedies, could not long hold a place, but were succeeded by tragedies written upon the classic models.

The Halian comedy produced characters that never varied, some of whom are supposed to have descended directly from the Mimi of the Fubula Atellana. This ancient origin is claimed for Harlequin and Panchinello, an English Punch, both of whom are buffoons, cowards, wags, and josters, like the Sannio of the Romans. Pantalone was a Venetian merchant; Dottore, a Relognese physician; Spaviente, a Neapolitan oraggadocic; Pullivenella, a wag of Apula; Giangurgolo and Coviello, two clowns of Calabria; Gelsomina, a Roman beau; Beltrame, a Milanese simpleton;

Brighella, a Ferrarese pimp; and As levchino, a blun-dering servant of Bergano. Thus each personage, clad in a peculiar dress, and furnished with a peculiar mask, was intended as a characteristic representative mask, was intended as a characteristic representative of some particular Italian district or town. To further this local personation, each actor spoke the dislect of the place he represented. Besides these, and a few other such personages, of which, at least, four were introduced into each play, there were the amorosco or innameratas,—that is, men and women who played serious parts; and also Sneraldina, Colombias, Spilletta, and other females, who acted the servettas and waiting-maids. These last wore no masks, and all spoke Tuscan or Roman. The pieces played by them were called Commedia dell' Arie. Goldoni adopted Harlequin and the rest of his mimic troop; but, instead of trusting to the extempore wit of the actors, wrote for them plots and dislogues.

France has boasted that when the classic drama was

France has boasted that when the classic drama was basished from every other stage in Europe, it found a home in Paris; and yet her drama, like those of other nations, was, during the 16th and a great part of the 17th century, horrowed from Spain. As the English owe the excellence of their stage to Shakespere, so France is equally indebted to Corneille. Cardinal Richelieu placed himself at the head of five dramatic authors, all of whom are forgotten, with the exception authors, all of whom are torgotten, win the exception of Corneille. It was at this period that the classical fetters of the three unities were imposed upon French dramatic poets. "The unities of action, time, and place must be observed." Corneille adds, "Personne n'en doute." The French are not only proud of their pretensions to classicality and their regard for the unities, but are enabled to boast with justice that they have discarded tragi-comedy,—that is, such pieces as comprehend two distinct plots,—one of a serious, the other of a humorous sort, each totally unconnected with the other. Corneille and Racine were, according to Sir Walter Scott, the Homer and the Virgil of the French drama. Even Voltaire himself was content to imitate these two great models, although he endea-voured to make a Turk talk like a Turk, and a savage like a savage, instead of in the brilliant metaphor and stitled sentiment of the buskined heroes of his predecessors. Molière, the founder of French comedy, followed the path marked out by Menander, and has closely expired some pieces from the Latin stage. Few satirists have attacked vice and folly so successfully; satirists have attacked vice and folly so successfully; and it should be remembered, when considering his marvellous power, that, while the English stage was fostered by a people, the French stage was merely the appanage of a court. Thus the sphere of the satirist was limited to the palace and its immediate surroundings. Schlegel observes,—"The object of French comedy is not life, but society,—that perpetual negotiation between-conflicting vanities, which never ends in a sincere treaty of nearest the embroidered dress. tistion between conflicting vanities, which never ends in a sincere treaty of peace; the embroidered dress, the hat under the arm, and the sword by the side, essentially belong to them; and the whole of the characterization is limited to the folly of the men and the coquetry of the women." This comedy of maners rather than of nature was overturned by the "Figaro" of Beaumarchais,—a production in which incident, intrigue, characters in high and low life, lively dialogue, and political satire, were so craftly intermingled, the whole being flavoured with a strong tone of hierationness, that it was received by the

tone of licentiousness, that it was received by the Parisian public with an almost frantic enthusiasm, The English drams was founded upon the Spatish model. "Forrex and Porrex," the first regular English targedy, was acted hefore Queen Elizabeth upon the 18th of January, 1861, by the gentlemen of the Inner Temple. A version of the same piece was acted in one of the minor London theatres in 1854, but without success. "Gammer Gurton's Needle," which without success. "Gammer Gurton's Needle," which was said to be the work of John Still, master of arts, and afterwards bishop of Bath and Wells, was first performed in Christ's College, Cambridge, in 1675. The jest of the piece turns on the loss and recovery of the needle with which Cammer Gurton repaired the breeches of her man Hodge. The popular characters are, the Stardy Beggar, the Country Vicar, the Clown, and the Strew. Thus we see that, at the very commencement, English comedy was founded on scharacters of middle and humble life,

and, unlike the Freuch, was not dependent upon the frivolities and fashions of lords, ladies, and courtiers. It is to be remarked, that as our first tragedy had no intermixture of tragedy. The influence of the plays of Shakapere upon poetry, the drama, and the world at large, is too universally recognized to need comment in a work of this description, even if the space prescribed to us were unlimited. It is enough to say that his transcendant genius and matchless power created a model, which never has, and perhaps never will be equalled. His historical plays throw a light upon his country's history; his tragedies are schnowledged masterpieces by the highest critics of every civilized nation; and his romantic dramas and counciles, though not faultless, abound with the errors of a genius innation; and his romand crames and considerate, though not faultiess, abound with the errors of a genus incapable of self-control, and too powerful to submit to the trammels imposed upon the dramatist by the pedantry of inferior minds. The tragedies of Jonson pedantry of interior minds. The tragence of Johan are distinguished for a sublime expression of moral sentiment. In comedy he occasionally followed the older Grecian school, as in the "Tale of a Tub," where, older Grecian school, sein the "Tale ot sea up, where, in order to ridicule his enemy, Inigo Jones, be trod in the path of Aristophanes. In the "Steple of News" and "Cynthia's Revels" he introduced allegorical characters, and personified abstract passions. In tracing the history of the English drams, we perceive the im-mense influence over his successors, of the plays of Shakapere. Massinger, a man of considerable general, endeavoured to unite the romance of Shakapere to the realistic humour of Jonson; and though he has to the realistic humour of Jonson; and though ne has to an extent succeeded, his love passages are infinitely less interesting and his villanies more revolting than are those of his two models. Beaumont and Fletcher, both men of remarkable talents, grafted upon Shak-spere's method of composition the boundless licenso of the Spanish school. Sometimes almost discarding probability, violating character, and therefore weakening, if not destroying, the interest of the plot, they compensate for these faults and irregularities by admirable for these lands and fregularities by admirable descriptive passages, elegant wit, passionate and tender dialogue, and rich humour. The plays of Shirley, of Ford, of Webster, and Decker, although now forgotten by the mere playgoer, and holding no place upon the boards of the theatre of the present day, abound with admirable passages and detached scenes of singular merit; and it is, doubtless, to the fact of the rude apology for scenery, and the eye of the spectator being entirely ungratified in the English playhouses of the 16th and 17th centuries, that we are indebted for that brillient band of distinguished poets known as the Elder Dramatists. Audiences crowded to the theatre, not to gaze on splendid scenery, but to listen to the literary production of the author and to the declamatory graces of the player. The great and ori-ginal school, founded by Shakspere and Jonson, and followed by Massinger, Besumont and Fletcher, and others, closed with the outbreak of the civil war in 1642. A proclamation shut up the theatres and dispersed the A procismation statt up the theatree and dispersed Lio players, almost all of whom took up arms for King Charles, in whose service many of them perished. One Robinson, an actor at the Blackfriers theatre, was killed by Harrison, the regicide, in cold blood, Har-sison declaiming the text from Scripture, "Cursed be he who doeth the Lord's work negligently." The woon uccamming the text from Scripture, "Cursed be be who doeth the Lord's work negligently." The most ancient English playhouses were, according to Malone, the Curtain, in Shoreditch, and the Theatre. In the time of Shakspere there were no less than nine theatres open,—three private houses, one in Blackfriare, the Cockpit or Phasnix, in Drury Lane, and one in Salisbury Court. The six public theatres were the Globe, the Swan, the Rose, and the Hope, on the Bank side; the Red Bull, and the Fortane. In the winter of 1648, the players at the Cockpit, while acting the "Bloody Brothers," were surprised by a party of soldiers in the middle of the play, and extrict to prison in their playhouse dresses. On Feb. 11, 1647, an act of parliament was passed that all stage-galleries, seats, and boxes should be pulled down, by warrant of two justices of the peace; that all actors of plays for the time to come, being convicted, should be publicly whipped; and all spectators of plays should, for each offence, pay five shillings. The Restoration may be said to have inducted the second period of the English drams. Charles II., who is his exile imbibed French

## Dramatis Persons

tastes, brought with him to England a relian for the heastles of the Franch stage. Director, Howard, and the authors of the day, forcered this taste, and herois plays were appleaded by holf the count and city. The heroig play, were appleaded by holf the count and city. The heroig play, were a ferred, and invested in the logues, drama, and processions. The heroes and heroines were all of one exactly virtuous pattern; about was entirely refined, and love of the most impossible purity. At the same lime, councy described felineation of character and contraction on plot, and endeavoured to chine only in dialogue. The atmosphere of alicentious court infested the stage; and authors strove by a succession of simari jesis and loose epigrams to amuse the wift of the town rather than to point a moral or wing a saticinal graph. The duke of Buckingham's famous saticinal graph. The duke of art, and tragedy and commend graphs of the famous hand graphs of art, and tragedy and commend graphs of the saticinal graphs of the stage is one that display of passionate tenderness winced in the Fernelc characters of Otway, and, despite some rant and fustian, of Lee. The 18th century asserted in genteel comedy, an entertainment that crashited the forbles of the higher classes; comedy of intrigue, in which plots and surprises succeed each of buckers, and English opera. (See Orexa.) To Garrick the stage is indebted for a revival of the plays of Shakapster; and to Sheridan for a description of comedy, that, to the polish and wit of the authors of the Congreve the Congress and Farquiar school, added humorous and distracteristic dialogue. George Colman the elder and George Colman the younger both contributed ad-mirable comedies to the rich repertory of the drama; mirable comedes to the non repertory of the drams, and Maturin, Lord Byron, Coleridge, and Joanus Baillie, were the authors of the tragedies produced in the early part of the present century. The two Kembies and Mira, Siddons, Edmund Kean, Charles Young, and Miss O'Neil, were of the same ers, one of the most brilliant of which the English stage can boast. The last attempt to maintain a high school of tragic art was made by Mr. Macready, at Drury Lane, in 1842. The events of the last fifty years are not matters of history, therefore we shall not dwell upon them. At present, English literature would seem to have aban-dened the drams, for our stage is almost entirely oc-cupied by translations from the French. The public have contracted a taste for the morbid, the spectral, and the horrible, united to illusions of the eye and mechanical contrivance. The causes for this decline are many; but it cannot be supposed that at a time are many; but it cannot be supposed that at a time when theafres are more successful speculations in a commercial point of view than ever, a taste so low can be long sustained. The actors deplore the exercise of the various arts that now prove so attractive; and there can be no doubt that, although many managers of theatres may realize large fortunes, the degradation of the art of acting will be the natural result of the unhealthy excitements that now pander to a depraced popular tests.—Ref. Art. Drama, by Sir Walter Scott, in Engyslopadia Britannica.

Dramatis Prasson. d'am'd-tis per-so'-ne (Lat.).

DRAMATIS PRESONE, dram'-ā-tis per-eo'-ne (Lat.), the various personages introduced in the course of a drama, or the actors representing the characters in

drams, or the actors representing the characters is of a greater quantity of goods than what would have brighter executed in plaster or marble is attended with influently, and requires considerable skill on the part of the artist and modeller. It must be allowed, that the costame of the present day is peculiarly mented for representation in the above materials; but, in many cases, additional effect is given to the figure, and its fittly disposed to suit the circumstances under which sterry is conveyed to us in a more striking manner, by the addition of a little drapery thrown around the nude forcit, the folds of which are carefully arranged and exitified granted, entitling the owner to receive the drawback. No drawback is given on damaged or decayed goods. Dawmarnen, draw-brig (Ang.-Sax.), a movable and skilfelly disposed to suit the circumstances under which the figure is represented. Thus, a short gare ment girt round the waist of a running figere, showing the content of the fore part of the thigh sad knee, and streaming out behind, gives additional force to be desired to the carp of the dich in front of the sort of the thigh sad knee, and streaming out behind, gives additional force to the same of part of the dich in front of the sort of the time and on the same of currantees.

## Drawbridge

ever drapery is used, it should be so contrived that it may give expression to the form of the figure, and aid is explaining the story that the sculpter wishes to convey to us in connection with his work. Many will remember the sconderful and exquisite manner in which the light drapery was treated that was thrown over the bead of the "Veiled Figure," by Month, that was arhibited in the Austrian court in the Great Brhibition of [ARI] tion of 1851.

DEASTICS, dels'-tiles (Gr. drostices, active, brisk, from drue, I affect), is a term generally applied to such medicines as are very violent in their action, particularly as purgatives; such as croton oil, jalap, &c.

DEAUGHT, draft (Ang. Sax.), a technical term used in Mar. to express the depth of water in which a chip can float; thus, if a vessel requires twelve feet of water to enable her to float, she is said to draw twelve feet, no order that her draught may be assily known; it is norder that her draught may be easily known, it is marked on the stem and stern-post.

DRAUGHT (Lat. kaustus) is a liquid form of medicine

intended to be taken at once, or at a draught; whence

DRAUGHTS, a game played by two persons on a board similar to that used in playing chess. Each player has a set of twelve pieces, which cousist of small round flat disks, made of wood or ivory; one set is black and the other white. The pieces must all be placed on the same colour, in alternate fours in the first three rows, before each player. The pieces must only more one square at a time, diagonally and forwards. If an opponent's piece stands in the way, there is no retreat,—the player must either advance or take his adversary's piece. A piece can only be taken, however, when there is a vacant square directly behind it; the attack-ing piece is lifted over and placed on this vacant square, while the piece leaped over is removed from the board. The object of the game is either to take all the adversary's pieces, or to hem them in so that he cannot play. The game increases in interest towards the clos sary's first line become king, that is, their power is doubled, and they can move backward or forward to all parts of the board. The game of draughts does not

all parts of the board. The game of draughts does not require so much science as chess, but is a favourite recreation with a great number of people. In Prance the game is called les Dames, probably on account of its having been always very popular with ladies.

DRAUGHTSMAN, drufts'-man (Ang.-Sax.), one who is skilled in the use of the pencil. A mechanical draughtsman is one who is skilled in making drawings of machinery, diagrams, maps, and plans, in which the use of mathematical instruments is involved.

DEAWDACE, draw'-bak (Ang.-Sex.), in Com., is a term used to signify the sum paid back by government upon certain classes of goods exported, on which duty has already been paid. The object of this is, obviously, to enable the exporter to compete in the foreign mar-ket on an equal footing with those of other nations. ket on an equal footing with those of other nations. If the amount of drawback exceeds the sum paids as duty, then it partakes of the nature of a bounty (which see). The general principle of drawbacks is not objectionable, though they may be so in particular cases. "To allow," says Adam Smith; "the merchant to draw back, upon exportation, either the whole or a part of whatever excise or inland duty is imposed upon domestic industry, can never occasion the exportation of a greater quantity of goods than what, would have been exported had no duty been imposed." Such encouragements "tend not to overcure that balance

the grain of which runs in a contrary directly DRAW-PLATE, a steel plate used in the m of metals, for the purpose of converting them is or bars. It is furnished with a series of gr holes, through which the metals are drawn. draw-plate is also applied to a metal plate put in of a fire or over the front opening of a freplat

of a fire or over the front opening of a freeless, to order to cause the air to pass through the fire, instead of over it, in its way to the chimney.

DRAY. (See Yautcles.)

DRAYS, dreems (Du. droom, Ger. frank), are disfined to be "trains of ideas presenting themselves to the mind during sleep." It frequently, if not always, happens during sleep, that while some of the manual faculties are suspended, others are still active, and are busy with numerous ideas which succeed each other with more or less regularity. This is dreaming. This characterized by an absence of consciousness with regard to external things, and an entire suspension of voluntary control over the current of thought, so that the principle of suggestion—one thought calling and voluntary control over the current of thought, so task the principle of suggestion—one thought calling and another according to the laws of association—has un-limited operation. The subject of dreams is one of the most intricate and perplexing in the entire field of mental philosophy, and it has not yet met with that amount of attention that its importance demands. Sirwilliam Hamilton believes that, "whether we received our dreams or not, we always dream." To have a recollection of our dreams does not prove that we have not dreamed; for it can often be shown that we have dreamed, though the dream has left no trace upon our memory. Many other philosophers have held the same opinion; among whom Kant, who distinctly maintain that we always dream when salesp; that to coses the dream we arrays arount when sales; 7 that the coase to dream would be to cease to live; and that those who fancy that they have not dream have only forgotten their dreams. The phenomena of dreams along that to prove what is now generally believed to be true; that different mental faculties have different portions of the begin suproposited to them. brain appropriated to them, and through which they act. One of the most remarkable features of dreaming is the rapidity with which the mind passes through a long series of events. Whole years may seem to the dreamer to have elepsed, and a multisude of mages may have been successively piled up before him, thou the time occupied therewith is known to have occup-only a few minutes, or even a few seconds. The only a let industry, drawn involving a long succession of supposed symptohas often originated in some circumstance that aroused the once originated in some curvametance that arouse aleeper, and taken place within the shock space proceded the state of full consciousness. The district of a dream is often to be traced to some sensions ing or impression. Thus Dr. James Cracery have one concession gone to bed with a vessel of hot will his feet, dreamed of walking up Mount Bins, a ing the ground warm under him; and on such sion, having thrown off the bedelothes in his ab sion, having thrown off the bedelothes in his sheep, dreamt of spending a winter at Hudson's Bay. Reid, having a badly-dressed bilists on his he dreamt of falling into the hands of Indians, and be scalped by them. We believe that many more of preasur of falling into the hands of Indiant, a scaled by them. We believe that many me dreams may be traced to this source that ago imagined, and that many of those unpleases that are sometimes found to precede librar consisted by facility or satestions of wint ordinary waking state we are unconscious. This way that indigestion is so fruitful a case

Dreams

pleasant dreams. Of the fire senses, touch is the most excitable during sleep, and most fingeredly modifies the character of our dreams. The sense of hearing is the next; and the least excitable of all our senses is that of sight. Our before in the resulty of the scene brought before us, and in the presence of external objects not before us, are among the most curious and important of the phenomene of arcams. Everything seems real and rivid before us. Dr. J. Cunningham attempts to emplain this, by maintaining that the affinity that arists between sensations and ideas is greater than is commonly inegined, and that "all thought is objective and pictorial." "We cannot think," he says, "without thinking of something, and that that something must be thought of a outside the mind. It is not our thoughts, but the things we think mind. It is not our thoughts, but the things we think of that are present to our consciousness; and thus our thinking consists of a series of visious."—(Macmillan's Megazine, 1802.) Be this as it may, we believe that this phenomenon cannot be adequately explained by referring it to "a complicated case of association," reserving it to "a complicated case of association," as is sometimes steempted to be done. It is said that dreams turn most frequently upon what has occupied our thoughts during the day, and that the most reseent associations occur more readily than those which are more remote. This, however, we do not think to be so much the case as is supposed. death of a friend may occupy the chief part of our thoughts for weeks or months, and yet during all that time he may never once appear to us in our dresus; and it is only when he ceases to occupy so great a part in our thoughts during the day, that he begins to appear to us in sleep. "It is not always," says Sir W. Hamilton, "the subjects that occupy us most when awake that form the matter of our dreams; and it is curious that the persons the dearest to us are precisely those about whom we dream most rarely. The mind of the man of business, when he is away from home most frequently returns in sleep to the scene of his labours, and it is only, perhaps, some time after be has again returned home that the beautiful scenery his insource, as a sub-base has again returned home that the beautiful scenery and pleasant associations that occupied his mind when away again recur to his thoughts in sleep. We are rather inclined to the opinion, that, as a general rule, those faculties are most in action during sleep that a general rule, for it is well known that frequently the mind may be so exercised during the day that sleep can only be obtained with the greatest difficulty at night; and in the same way particular faculties may be so excited during the day as to continue in action also as excited during the day as to continue in action also in sleep; but generally a due amount of action demands a due amount of rest. But the phenomens of dreams are yet too little studied to enable us to assert much with certainty regarding them; and in all probability they differ very much in their nature and character in different individuals. It is commonly said that nothing supprises us in our dreams. This, however, is by no means uniformly the case. We do, seet, is by no means uniformly the case. We do, indeed, often see persons that are dead, or in a distant country, or witness events that have happened long ago, in our dreams, and feel no surprise; but sometimes, also, the idea that the person is dead or in a distant country, or that the event is matter of history, also occurs to us; then we are surprised, and we begin to think that we are dreaming. Or we find ourselves on some desert island, or the inhabitant of some gorgroup palace: we are surprised, and begin to cogitate how we came there. It is said, too, that there is a great goods pance: we are surprised, but negin to cognate how we came there. It is said, too, that there is a great distinction in the ordinary play of the emotions; that we may walk on the brink of a precipice, or see ourselves doomed to immediate destruction, and yet feel most the slightest emotion of fear; that we may perform the most rithless crime without computation, and see what would in our waking hours cause us unmitigated grief, without the smallest feeling of sorrow. This is by no makes immissingly the case, or even, so far as our own personnal empersone goes, is it so generally; but here, too, we believe that the nature of the dream differs in different individuals. Frequently the scenes that appears to us in our dreams are of the wildest and most arrows description. All probabilities, and even possibilities, of time, place, and giroumstance, are violated, and yet they reachy strills us as untrue or improbable. There is also in several a remarkable want

of coherence in our dreams, and a complete incongruorances in the thoughts and images that pass through
our minds. Sometimes, however, the very reverse of
this takes place, and the reaconing or imaginative
powers may possess a strength unknown to them in
their ordinary condition. Thus Condences saw in his
dreams the final steps of a difficult saleulation that
had puzzled him during the day; and Condiliae states
that when engaged with his "Cours d'Eude," he
frequently developed and finished a subject in his
dreams which he had broken off before retiring to rest.
The circumstances under which Mr. Coleridge composed his fragment called "Kubis Khan" have been
described by himself, as follows:—He had fallen asleep
in his chair while reading in "Purchas's Pilgrimage"
of a palace built by Khan Kubla, and remained asleep
for about three hours, during which time, as he himself tells us, "he could not have composed less than
two or three hundred lines,—if that, indeed, can be
called composition in which all the images rose up
before him as things, with a parallel production of the
corresponding expressions, without any sensation or
consciousness of effort." On waking, he instantly sat
down to commit it to paper; but, after having written
so much of it, he was called away by a person on business, and when he returned to the task, the poem had
vanished from his memory. The popular belief that
there is something supernatural in the hasture of
dreams, and that frequently in this way events are
revealed that are about to happen, has been held from
the carliest times, and is shared in by many wellinformed persons in the present day. Many of the
instances of remarkable dreams may, doubtiess, be
explained from natural causes, but there say others so
well authenticated that we cannot altogether disoredit explained from natural causes, but there are others so well authenticated that we cannot altogether discredit them, that are manifestly unexplainable by any natural means. If we admit the testimony on which these dreams are given, we are driven to confess that they arise from causers and are subject to flows, of which we are ignorant. "At present, we see only the particular are ignorant. "At present, we see only the particular interpositions, particular events, belonging to another system, which we call supernatural, which is governed, however, doubtless, like our own, or the natural system, by general laws, and which moves, perhaps coordinately with this to a common end, although we know not the laws of that system, nor to a connection between it and our own."—(English Cyclopedia.) It is, indeed, an interesting question,—what purpose do dreams serve in the animal scouomy? There can be little doubt, we think, that they exert a certain inlittle doubt, we think, that they exert a certain in-fluence upon the character. "A particular tendency," says Sir William Hamilton, "may be strengthened in says Sir William Hammion, "may be strengthened in a man, solely by the repeated action of dreams." "Dreams," says Sir B. Brodie, in his "Psychological Inquiries," "are, at any rate, an exercise of the imagination. We may well conceive that one effect of them may be to increase the activity of that faculty during our waking hours; and it would be presumptions of the state of the s during our waring nous; and a would purpose beyond this, in the economy of percipient and thinking beings." "If," says Pascal, "we dreamt every night the same thing, it would perhaps affect us as powerfully the same thing. as the objects which we perceive every day. And if an artisan were certain of dreaming every night for twelve hours that he was a king, I am convinced that he would be almost as happy as a king who dreamt every to elve hours that he was an artisan." Hence it is of some pe amost as happy as a king who dreamt every twelve hours that he was an artisan." Hence it is of some importance to study the art of procuring pleasant dreams, on which subject Dr. Franklin has an essay. A more accurate knowledge of the nature of dreams would tend to illustrate many of the mirre obscure mental phenomens. The analogy between dreaming and insanity is very striking. There is the assis wild disorder of the mental faculties, the same rapid and tunultuous thoughts, the same rejoid apparent to the most recent written on this subject is M. L. F. Alfred Maury, whose work, "Le Sommeil et les Rêves, Etudes Physhologiques aur ces Phénomènes et les divers Rists que all raitachent." Paris, 1801, is well worth the attention of any who are desirous of studying this subject. He cande unmerons experiments upon hintself, and had a second person by him to record what he might say or what gratiurs he might make during sleep, and to wake tim anddenly at any moment that might seem to promise a favourable

result. Many of his observations, however, we are inclined to regard as peculiar, and not to be generally characteristic of dreams; and homes we are inclined to question some of the general principles which he deduces from them; but it is only by the multiplication of such a knowledge as to be able to distinguish the general from the particular, the rule from the axception. Deed from the particular, the rule from the axception. Deed from the particular, the rule from the axception. The general from the particular, the rule from the axception. The general from the particular, the rule from the axception. The general from the particular, the rule from the axception. The general from the purpose of bringing up shells, &c. The common cyster is obtained by dredging. The dredge employed is a bag-net, composed of iron rings linked together so as to form meshes. The mouth is made of sheet-iron, and acts as a scoop when the dredge is lowered, and drags along as the bost sails over the cyster-beds. Dredging has lately been much practised by naturalists for the purpose of investigating animal life in the ocean. The late Professor Forbes, by a series of interesting experiments, was true enabled to show that there are zones of animal life corresponding with that there are zones of animal life corresponding with different depths of the sea. The naturalist's dredge is of much lighter construction than that of the oyster dredge, and recembles more a shrimp or sole-dredge but it varies according to the bottom to be explored.

but it varies according to the bottom to be explored.

DEBDGING-MACHINE, a machine employed for the purpose of clearing out or deepening the channels of rivers, harbours, &c. The most effectual machine is the bucket dredging-machine; it is in the form of a large barge with an open hold. A long stage, in the form of an inclined plane, overhangs the side of the barge, having a strong wheel at each end working an endless chain. To this clasin a series of perforated iron buckets is attached, each with a shovel-shaped steel mouth projecting on one side. The buckets, which ascend on one side of the inclined plane and descend on the other, are so contrived as to descend which ascend on one side of the inclined plane and descend on the other, are so contrived as to descend empty. On reaching the lower wheel, the shovel-shaped mouth digs into the bottom, and as it turns round is partially filled with rubbish, and passes upwards to the upper wheel. As it is inverted while passing over the upper wheel, it discharges its contents into the open hold of the barge. Every succeeding bucket on the endless chain continues the action, and the depth of working can be increased or decreased by changing working can be increased or decreased by changing the inclination of the framework. The more powerful dredgers, instead of emptying the buckets into their own holds, discharge them into other barges drawn up alongside. Dredging-machines are worked some times by steam-engines, sometimes by the action of an undershot wheel, and sometimes by horse-power,-the undershot wheel, and sometimes by horse-power,—the horse moving round a circular path in the barge. Some very large and powerful dredging-machines are in use on the rivers Tyne and Clyde. One of the most perfect forms of dredging-machine was that constructed by Mesare. Bury, Curtis, & Kennedy, of Liverpool, for deepening the bay of Santander, in Spain. \*#he engine was a side-lever, low-pressure condensing marine engine, of 25-horse power, having a cylinder of 28 inches diameter and 3 feet stroke (crank making 28 revolutions per minute); the cylinder was supplied with abort D-valves of brass. The air-pump had a diameter of eighteen inches, lined with brass \*#ho of an inch thick, with a brass lined with brase  $\frac{1}{\sqrt{2}}$ , of an inch thick, with a brass bucket, brass discharging- and foot-valves; rod of wrought iron, cased with brass. The engine was fixed on a cast-iron bed-plate  $\frac{1}{2}$  inch thick, secured to the keelsons of the vessel by aixteen  $\frac{1}{2}$ -inch thick the inch bolts; the condenser was cast solid on the bed-plate. The side-levers were 9 feet 31 inches long, 19 inches broad in the middle, and 14 inch thick in the plate; the main centres were keyed into the contre on each side. There were two fly wheels on the crank-shaft, each 13 feet 6 inches in diameter, the rim being 9 inches deep by 5 inches broad on the edge. The crank-shafts were constructed of cast iron, of 7 inches diameter in the journals, and supported at the ends by brackets fixed to the side of the boat. The engine was provided with a governor, which was driven from the crank-shaft by a bult and pulleys. The framing, columns, and crank pedestals were east in one piece. The boiler was il feet long, 8 feet wide, and 8 feet high, with steam-chest 5 feet long, 1 feet 6 inches wide, and 1 foot 8 inches high: With respect to the dredging machinery, the spar-wheel,

on the fly-wheel shaft which connected the engine on the nywheel sums which connected the engine and other wheels for working the machine, was 6 feet 6 inches in diameter to the pitch-line, 24 inches pitch and 8 inches broad on the edge; and on the piten and a neues or our on the range; and a hant of this last-mentioned wheal there was fixed a wheel of 4 feet 5\frac{1}{2} inches diameter, 3\frac{1}{2} inches pitch, and 10 inches broad on the edge, which worked into a wheel keyed on the bucket-abat, 8 feet in diameter, of 3\frac{1}{2} inches, pitch, and 10 inches broad on the edge. The main, or bucket-abatic on which the 3-foot wheel was keyed, was of east iron as far as the coupling-boxes on each side; the ends of this shaft rested on pins of 8 inches diameter, fixed into the tumbler-shafts, which were of wrought iron, and turned to receive the tumblers. The shaft for the lower tumblers was also of wrought iron, and worked in chilled cast-iron bushes. The upper tumblers were square, with hoops of wrought iron a inches by 1\frac{1}{2} inch (steeled on the corners); the flange on one side was made loose for the purpose of putting the hoops haft of this last-mentioned wheel there was fixed a was made loose for the purpose of putting the hoops on. The lower tumblers were square also; the part under the bucket-link was chilled. There were four steel knives in each flange, for the purpose of cutting the soil before the bucket. The hangers, for carrying the bucket-frames, were of cast iron, the inner one firmly bolted to the side-framing; the outer one was fixed on the end of a transverse beam. The bucketframes or ladders were 48 feet long between the centre of the upper and the centre of the lower tumblers; or one upper and the centre of the lower tumblers; they were made of the best English oak, each side in two pieces, 12 inches by 6 inches, and bolted to the cast-iron brackets at each end with 12-inch bolts. The buckets were made of boiler-plate half an inch thick, and welded at the corners. The bucket-links were of wrought iron, with a ring of steel 12 inch thick welded into the eye of each link. The rollers on the bucket-frame, for carrying the buckets, were 9 inches in diameter. The coupling-boxes on the bucket-hait were for the purpose of disengaging the tumbling-shaft when one row of buckets was required to work. These coupling-boxes were also fitted with to work. These coupling-boxes were and attention a friction-strap to prevent accidents to the machinery, a friction-strap to prevent accidents to the machinery. should the buckets meet with any obstruction. The mitre-wheel on the bucket-shaft, 2 feet 3½ inches diameter, worked into a mitre-wheel keyed on the end meter, worked into a mitre-water keyed on the ead of an upright shaft; and on the lower end of this shaft there was another mitre-wheel, which worked into a mitre-wheel keyed in the chain-barrel shaft. The barrels for hoisting the end of bucket-manner were of cast iron, with a brake-wheel fixed on the end for lowering the frame when the barrel is disconnected from the intermediate shaft by the couplingbox; the handles of the coupling-box and also the brake-handle were placed on deck. The rope gearing for hauling the boat forward received motion from the upright shaft in the following manner:—A mitre-wheel was fixed on the upright shaft, working into another mitre-wheel on the intermediate shaft, and on another mitre-wheel on the intermediate shaft, and on this shaft there was a spur-pinion working into a wheel on the capstan-head shaft. The capstan-heads were of cast iron, with a coupling-box and friction-wheel, the handles of which were placed on deck. On this shaft there was a pulley two feet in dismeter, which was driven by a belt from the fuzze-pulley before mentioned

Danss, dres (from Fr. dresser, to make straight), a term applied to the body-coverings used by all but the most uncivilized human beings for the purposes of warmth and ornament. In tropical climates, the origin of dress was most probably ornament; but in proceeding from the equator to the poles, man would find it necessary to provide himself with clothing which would protect him from the inclemency of the weather. would protect him from the inciencing of the weather. Skins and furs, and those vegetable products which could be manufactured readily, would, in all likelihood, form the first garments; while with the progress of civilization, more complicated textures, such as those of wool, hair, flar, silk, &c., came into use. The dress adopted is different nations differs in form and in the substances employed, but in general is actived to the climate in which it is worn, and the occupations of the people. In most of the countries of Europe, among the upper and middle classes, one style of dress adopted, varying at times according to the diotates of fashion. But all the slight changes of late years, with

word is often used as an abbreviated term for the Glacial Drift of the Pleistocene period. (See GLACIAL

DEPOSITS.) DEVLL, drill (Du. drillen, Sax. thirlian), a tool used for boring holes in wood, metal, stone, bone, &c. It stone, bone, &c. It is formed in different ways, according to the kind of hole it is required to make, and the material which it has to penetrate.

Drills for boring iron have pointed heads, with sharp edges projecting from them, that cut in different directions. Those for boring wood are like an auger or large gimlet, or they are broad and flat, with a pro-jecting spike in the centre and cutting edges on either side : drills of this form are called centrebits. These tools are worked by a rotatory motion im-parted to them by a cranked handle, having a socket and spring at one end to receive and hold the drill, and a boss at the other, against which the workman presses his chest; or by a bow of steel, with a strong piece of catgut at-tached to it loosely enough to admit of its being passed once or twice round a pulley, through the cen-tre of which the tool passes. The workman presses the drill against the material that he is boring by his chest, which is protected by a plate of metal. A very fine example of a drillingmachine, emanating from the workshop of the celebrated mechanicism Sir Joseph Whitworth, of Manchester, may be here described. This machine answers all the purposes for tools of this kind are

its construction and motions, and have the same letters of reference. A. A. A. A. indicate the form of the cast-iron framing of the machine, upon which all the

very few exceptions, seem to be tending towards a more simple and appropriate style of dress.

Dairr, drift (Dan. drift), in Geel., a term signifying that which is driven; "as drift-wood, wood carried plate TT, intended to reat solidly, and without any down by rivers, and driven by tides and currents to distant shores; sand-drift, and driven and accumnitate to the workshop of the main frame a strong bracket is lated by three strong bracket is upper portion of the main frame a strong bracket is

cons and work-table. Fig. 2 is a front view of the spindle b and back-speed spindle of the machine, agreeing in its letters of reference with the spindle b and back-speed spindle of the machine. Upon the spindle b and back-speed spindle b, of three fig. 1. The other figures are drawings of parts of the speed.

The other figures are drawings of parts of the speed.

The speed-cone B is loose upon the shelt, and only a speed spindle of the spindle b. communicates motion to it by means of the spur-wheel C, which is keyed upon the spindle, and to which the cone can be attached by a stud-pin and nut

#### Drill

at c. This wheel gears with the pinion E, on the same spindle which carries the wheel M'; this in turn gears with the pinion N, which is fast upon the end of the cone B, but runs loose upon the cone-spindle b. This arrangement is in every respect the same as the ordinary back-speed of a lathe, and serves the same

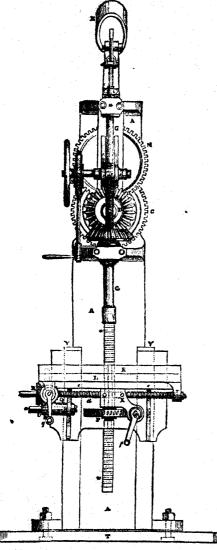

Fig. 2.

purpose. Supposing the back-speed removed, the cone, being driven by its belt, causes the spindle b to revolve, in consequence of its attachment to the fast-wheel C, and at the same time gives motion directly to the bevel-pinion D, on the end of the spindle. This again gears with the bevel-wheel F, on the drill-spindle GG, which is free to alide vertically in the eye of the wheel, while at the same time it is prevented

## Drill

from revolving in it by a sunk feather. By this means three different degrees of quick speed may be communicated to the drill. But let the back speed be in gear, as represented in the drawing (fig. 1), and let the stud-pin c be removed, and the cone thereby loosened from its attachment with the wheel C, the

notion being communicated to it will not drive the shaft b directly, as before; but the pinion N, being fast upon it, will give motion to the wheel M, upon the same spindle with the pinion E. This last will therefore make the same number of revolutions as M, but being less in diaber of revolutions as M, but being less in diameter, will convey a proportionally less velocity to the wheel C, with which it gears, and which it consequently drives with a speed diminished in the ratio of the gearing pairs. Now the wheel C, being fast on the shaft b, conveys to the bevel-pinion I) the same diminished speed, and this cash to the dell'applied G C. This and this again to the drill-spindle G G. reduced speed may of course be varied, as before, by placing the belt on one pulley or other of the speed-cone. Behind the pinion E there is a recess cast in the framing, to allow it to enter when the back-speed wheels are to be thrown out of gear: and it may be remarked that this speed-gear is only required to be in action when the machine is employed in boring holes of up-wards of an inch and a half in diameter. The wheel F is cast with a long hollow boss, which is turned and fitted into a brass collar in the lower branch of the carrying-bracket, as seen in fig. 1. This collar is kept in its place by a cover bolted over it, as shown in fig. 2. As already observed, the drill-spindle passes through the wheel F, which thus serves as its lower guide. The upper end of the spindle is at the same time guided in a collar similarly fitted into the time guided in a collar similarly fitted into the upper branch of the bracket at a, and is thus guided vertically in ascending and descending. In the drawings it is shown at the lowest limit of its travel. To the top of the drill-spindle is attached the back-weight H by a jointed lever and guide-link, which embraces the top of the spindle and moves upon a vertical guide-rod, kept firm in its place by having its lower end held by a screw nut in a socket cast in the brucket, in the manner of a bolt, a ruff forged upon the lower end of the rod answering to the upon the lower end of the rod answering to the head of the bolt. The drill-spindle is itself screwed towards the middle of its length, it is then embraced by two screw-wheels (J, J), between which it turns, and which serve the purpose of a unt to feed down the spindle in the operation of drilling by an arrangement which will be presently described. K is the table upon which the article to be bored rests, and to which it can be held firmly down and adjusted by Theaded bolts and glands in the usual way when thought necessary. The table, it will be observed, is recessed and grooved to receive and retain the T-heads of the holding-bolts, as fully shown in the horizontal section, fig. 3, and the side view, fig. 4. When the article is much smaller in area than the surface of the table, the fixing bolt-head can be entered at any convenient point of the surface by the recesses k, k, and slid forward until it passes below the projecting ledges of the recess, where it is retained. The common mode of running two sets of inverted dovetail grooves at right angles to each other, lengthwise and across the table, seems, however, preferable to this mode of partially re-cessing the surface. The table is itself supported

cessing the surface. The table is itself supported upon the sole of the large carriage-bracket L, which is strengthened by two ribs cast on its under side. This bracket is attached to the framing A.A. by two pieces Y, Y, which are bolted upon it, and planed true to the angle of the inverted bevel edges of the broad face-rib of the main frame. These edges are also planed where they ment the oblique faces of the pieces Y, Y. By this means a joint is formed which allows of a sliding motion vertically; but slove not admit of any deviation laterally. When the alides become loose by waaring of their surfaces, the pieces Y, Y admit of being

Drill

Drill

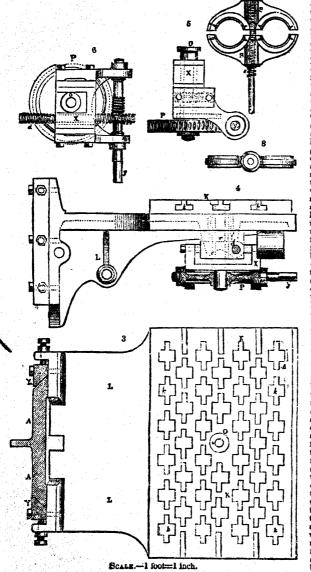

tightened by means of pinching screws fitted against tightened by means of purchase states against them through continuous sough cast on the bracket.

This arrangement is fully explained by figs. 3 and 4.

This bracket is raised and depressed by means of a which will either be raised or lowered according as the crank is turned in one direction.

of the machine, so as to form an integral part of it. By turning the hand-crank on u, it is thus manifest that the motion will be transmitted to the bracket,

or the other. The table K has or the other. The table K has a double movement upon the sole of the carriage-bracket; one movement is circular, and the other is in the direction of the length of the table. The circular movement is effected by means of the hand-orank p upon the spindle #, carried in bearings formed upon the box X, which thus serves as a centre of rotation. On the spindle y is formed a worm, which, gearing with the worm-wheel P on a stud projecting downwards from the table K, conveys the motion of the handle p to the table. This arrangement is well shown separately by the plan, fig. 6, and the elevation, fig. 5. This last corresponds to the view orresponds to the view given in fig. 2. Opposite views of it are also given in figs. I and 4, the last on an enlarged scale. It will be observed that the stud on which the wormwheel P is fixed is cast bollow, and is fitted into the table K by a key at o, shown in fig. 3. The lateral movement of the table is effected by a different arrangement. A recess in the form of a parallelogram is east in the sole of the carriage-bracket L, with projecting ribs (e, e) on its under side, to serve the double purpose of giving strength to the sole plate and of forming guides, against which the cover of the travelling-box X may slide, the surfaces in contact being planed true for that purpose. The motion is that purpose. The motion is communicated by means of the hardle q (figs. 1 and 2) upon handle g (tigs. I and 2) upon the spindle which carries the bevel-wheel Q, seen in fig. 2, and partially in fig. 1; also se-parately in fig. 10. This spindle has its bearings attached to the bracket L, and its wheel gears with the equal wheel R, upon the end of the screwed spindle d, which has its bearing (r) also attached to the sole-plate of the attached to the sole-plate of the carriage-bracket, and works in a long nut or internal screw formed in the cover of the travelling-box X. (See fig. 2 for the general arrangement, also figs. 4, 6, and 9.) By turning the handle q, it is thus clear that the piece which serves the nurses of a nut on the the purpose of a nut on the screw d will be carried along in screw a will be carried along in the direction of the length of the serew; but the nut being attached to the table K, the whole will be moved simulta-neously in that direction. By means of these two motions, any point of the table K can be brought under the axis of the brought under the axis of the

brought under the axis of the drill; and by the means of verticate and expansion of the spur-pinion U, shown in combination by figs. 1 The feed of the tool during the operation of boring and 2, and separately by figs. 11 and 12. This pinion gears with the spur-wheel V, parally seen in figs. 1 and 2, on the same spindle with the pinion W, fig. 1, which the same spindle with the pinion W, fig. 1, which the same spindle with the pinion W, fig. 1, which the same spindle with the rack w, let into the frame AA the axes of these wheels are placed two pulleys, the

part of the drill-spindle revolving between them, some minor fault, which he has to go through in heavy part of the drift-spindie revolving between them, they will act as a stationary, and cause the spindle to descend through a space equal to one-third of its screw during every revolution. Again, suppose the pulleys and wheels tree, the screw of the spindle instead of descending will simply cause the wheels J, J to results on their wast through a space gould to one to revolve on their axes through a space equal to one

marching order.

DRILLING, in Agriculture, is a mode of sowing by which the seed is deposited in regular rows, equally distant from each other. "It has been practised by

distant from each other. "It has been practised by gardeners from time immemorial, and from the garden it has gradually extended to the field. In those countries where maize, or Iudian corn, is extensively cultivated, the seed is always deposited in rows; and during the growth of the plants, the soil in the intervals is repeatedly hoed and stirred to a considerable death. to a considerable depth, as is likewise the prac-tice in vineyards. This cultivation not only keeps the land free from weeds, but, by allowing the dews and the influence of the atmosphere to pene-

rarely employed.

DRINKING USAGES (Sax. drincan, to drink; Fr. usage, usage).—From the earliest times of remote antiquity, there have always been special usages connected with the custom of drinking. Amongst the ancient Hebrews, the drink-offering constituted one of the most solemn parts of their religious ceremonies. The patriarch Jacob poured out a drink-offering on the pillar of stones which he had erected to mark the place where he had talked with God (Gen. xxxv. 14). In the 15th chapter of Numbers there are special directions for the pouring out of drink-offerings of wine with the burnt-offerings, to be "a sweet savour unto the Lord." Amongst the ancient Greeks and Romans, the pouring out of libations to the gods was an ordinary religious ceremony. They were not only offered before solemu prayers, but also before meals. In the latter case, the host, before the guests began to eat, poured a small quantity of whe upon the floor, as a sort of propitation to the gods. This practice was somewhat equivalent to our grace before meat. It was also the custom at times to drink to the health of the guests. From usages such as these, in after-time, arose the custom of pro-

Fig. 12.

Fig. 10. Fig. 11.

tooth during every revolution of the screw. Now. between these extremes my amount of feed or downward motion of the drill-spindle may be obtained by simply retarding the motion of the wheels, by means of the friction-collars S, S, which embrace the small pulleys on their uxes; for the friction of the collars being less than to prevent entirely the motion of the wheels, and, at the same time, greater than to allow a tooth to pass during a revolution of the spindle, a downward motion of the spindle must thus be pro-duced at pleasure, by the contrivance of the friction-collars, shown separately in figs. 7 and 8. These collars are formed in two halves (8 8), with bosses joining the segments, pair and pair; these bosses are reverse-ecrewed internally, the thread of the one to the right, and that of the other to the left; and being placed in a rod (s s) correspondingly screwed right and left, they are made to approach or recede according as this rod is turned to the right or left, and to as this rod is turned to the right or left, and to embrace more or less closely the pulleys upon which they are placed. This screwed rod is prolonged, and has a bandle placed in its under end, by which the required degree of friction can be adjusted at pleasure (see fig. 2). The friction-collars are lined with copper, for the purpose of increasing the friction; for its manifestly of advantage to obtain as much friction on the pulleys as possible with the least amount of pressure. This arrangement has also the advantage of pressure. This arrangement has also the advantage of allowing the tool to be speedily withdrawn; for on slacking the friction-collars, the balance-weight H will raise the spindle in ordinary cases, and when the tool has a hold in the hole which is being bored, the balance-weight can be assisted in its office by the hand wheel placed on the axis of one of the wheels (J): the wheel and screw will thus for a time be converted into a pinion and rack. The figures of Whitworth's excellent machine, and the description of it, are taken from a useful and instructive work, one we commend to every mechanical student.—Mr. David Scott's "The Engineer and Machinist's Assistant."

Drill, in Mil., the general name given to the exercises by which a soldier is qualified for his duty. Squad, or setting-up drill, teaches him how to march in slow, quick, and double time, to go through his facing. and to perform certain simple evolutions from the halt or when marching; these are combined with pos-ture exercises, called extension motions, which tend to give the soldier a good carriage and an erect inilitary figure. When the recruit is dismissed from equad drill, which is taught to small batches or squads of men by a sergeant appointed for the purpose, he learns company drill, the manual and plateon exercise, and position drill; he is then competent to go through a course fore drinking. Waskall is evidently derived from this fore drinking. Waskall is evidently derived from this

origin; but it is attributed by some to an occurrence said to have taken place between Rowens, the daughter of Hengist, and the British king Vortigern. The king was at an entertainment at the castle of The king was at an entertainment at the castie of Heugist, and, during a feast, lost his heart to the fair Rowens, who, kneeling gracefully before him, presented a cup of wine, saying, "Liever kyning, wass kell (dear king, your health). The wes kell of the Saxons was, however, in use before that time, and was equivalent to the "Your health" of the present day. The practice of pledging a guest before drinking arose from a necessity of showing that there was no poison in the wine, or that there was no the guest while wine, or that there was no danger to the guest while he drank. It originated in the 10th century. The introduction of Christianity did not at all contribute to abolish the practice of using the wassail cup. It began, on the contrary, to assume a religious aspect; and in the larger monasteries, amongst the monks of old, the wassail bowl was placed at the right hand of the abbot in the refectory. It was handed round to each, and was called Poculum Charitatis. In the unieach, and was called Poculum Charritatis. In the universities a similar cup is still passed round, called the grace cup. In the dinners given by the public companies of the city of London, after the cloth has been removed, the master and wardens rise, and "drink to their risitors in a loving cup, and bid them all heartily welcome!" A silver cup filled with warm spiced wine is then handed round to all present. Some of the drinking-cups belonging to the priesthood in the Middle Arge were of the most costly workmanshin. Middle Ages were of the most costly workmanship. That of Thomas à Becket is still preserved; it is made of ivory, mounted with silver, and studded on the summit and base with pearls. Round the cup is an summit and base with pearls. inscription, "Vinum tuum bibe cum gaudio" (drink thy wine with joy); but round the lid, deeply engraved, is the restraining injunction "Sobrii estote" (be moderate). The word toast, with regard to drinking usages, is comparatively modern; it originated in the usages, is comparatively modern; it originated in the practice of putting a piece of toast in a jug of ale. According to "The Tatler," the word toast was first applied to the drinking of healths at Bath, in the reign of Charles II. A celebrated beauty of the time was in the large public bath, and a number of her admirers were standing around. One of them took a glass of water from the bath and drank to her health; while another who was standing by, half tipsy, offered to jump in, saying, that although he objected to the liquor, he would like to have the tosat. From that time the word was applied to drinking the health of any beauty at private parties, and, in time, all sorts of subjects were toasted at public and private feasts. Toasts also began to be accompanied by cheers; and Toasts also began to be accompanied by eneers; and at the present day, at large public banquets, toast-masters are generally appointed, who not only give out the subject of the toast, but lead the cheers which follow. Many drinking usages are connected with domestic events, and seem to have been handed down from ancient times. The custom of drinking at births, christenings, and marriages, can easily be accounted for; but the strangest usage of all is the practice of drinking at funerals. The wakes held in Ireland and orning at tonerals. The wakes held in tream and some parts of Scotland have been long maintained, and are still kept up by habit. They probably owed their origin to the want of excitement amongst the phlegmatic northern nations, and the long dark nights in a cheerless climate.

DEFERS, drinks (Ang. Sax.).—In order to dilute our food and repair the constant waste of fluids that is taking place in our system, a certain quantity of liquid must be taken into the system; and so necessary is must be taken into the system; and so necessary is this, that one can bear hunger better and longer than he can do thirst. Water is, undoubtedly, the natural drink of mail, and, in a perfectly healthy condition, is preferable to any other; but there are many others which, in certain conditions of the body, or through habit, may be taken, not only without injury, but with advantage to the health, if only taken in moderation; such as alsoholic drinks. Much depends upon the purity of the water one uses in the preservation of health, and the presence of even very minute quanti-ties of earthy or putrescent matter may produce the most pernicious results. Thus a very minute impreg-nation with lead is quite sufficient to develop all the symptoms of chronic lead-polloning if persevered in for a sufficient length of time. Again, an excess of the 702

saline ingredients which appear to be innocuous in small quantities, may produce a marked disorder of the digestive organs, and through them of the system generally. The injurious effects of the use of impure digestive organs, and through them of the system generally. The injurious affects of the use of impure water are also manifest in the extraordinary augmentation of the liability to attacks of such zymotic diseases as may at the time be prevalent. For the purification and preservation of water, numerous ingenious methods have been adopted; and one of the most approved is by means of patent filters, in which the water is pussed through alternate layers of sand and charcoal. (See FILTEL) Where there is reason, however, to suspect much injurious contamination, the process of holling should never be comitted; after process of boiling should never be omitted; after which it may be strained and filtered, and lastly agitated in contact with the atmosphere, in order to agitated in Contact with the stimosphere, in Order to restore to it its natural proportion of air. Much has been written for and against the use of alcoholic or fermented liquors; and it is one of those points on which medical men are very much divided. Without going into the arguments advanced on either side, we may give it as our opinion, that while in a healthy and natural state of the human frame, their use may be, and probably is, in some measure injurious; yet that, from the tear and west that most people have to endure in the present state of society, more or less of endure in the present state of society, more or less of alcoholic liquor is necessary to maintain the body in even the ordinary state of health. The quantity of drink required varies according to the climate, the nature of the solid food taken, and individual peculiarities. Most persons generally consume too much of liquids; and this is to be particularly guarded against during meals. By diluting the gastric juice, it presents the food from height property stead upon. Perfure the the food from being properly acted upon. Perhaps the best time for taking drinks of any kind is an hour or two after meals, as is shown by the degree of thirst which is then felt. Drinking large quantities of water is sometimes employed with beneficial effects in the cure of certain diseases. By exciting the vascular system and its connected secreting organs, it tends to remove from the blood various effets or noxious matters. On the other hand, a total abstinence from drink for two or three days is recommended as an effectual mode of stopping fluxes and of relieving catarris,

inflammations, and congestions. (See Com.)

Driven Ant, dri'-ver, the local name of a species of hymenopterous insects belonging to the fam. of Auts. DRIVING, FURIOUS, dri'-ving fu'-re-us (Sax. drifun, to drive; Lat. furiosus, furious), which was a misde-meanor by common law, was declared to be a statutory offence by 1 Gec. IV. c. 4, which declares that if any person shall be maimed or otherwise injured by reason of the wanton and furious driving or racing, or by the wilful misconduct of any coaciman, or other person having the charge of any stage-coach or other public carriage, the offender shall be guilty of a misdemeanor, carriage, the offender shall be guitty of a misdemeanor, and punishable as such by fine and imprisonment. By 2 & 3 Will. IV. c. 120, the provisions relating to stage-coaches were consolidated, and penalties imposed for furious driving, or other offendes against the act. This act was amended by 3 & 4 Will. IV. c. 48; 2 & 3 Vict. c. 66; and 5 & 6 Vict. c. 79. The provisions relating to backney and stage coaches in London will be found in 1 & 2 Will. IV. c. 22; 6 & 7 Vict. c. 86; 13 & 14 Vict. c. 17; and 16 & 17 Vict. c. 33.

DROFE, (See Bre.)

DROFE, (See Bre.)

DROFE, droft-se (Gr. hadrops, from hador, water, and ops, aspect or appearance), in Path., is a disease characterized by the accumulation of watery fluid in one or more of the shut cavities of the body, or in the areolar tissue, or in both, independent of inflammation. In a state of health, the capillaries, which ramify every part of the body, constantly pour out upon every surface, into the most minute cells as well as the great cavities, a watery fluid to moisten the parts, and thereby facilitate motion and prevent injury from friction. This watery fluid is speedily taken up

Drowning

by another class of vessels, called the absorbents, which carry it back to the general circulation. When the by another class of vessels, called the absorbers, which carry it back to the general circulation. When the healthy condition of these organs is impaired, either from the exhalents acting too powerfelly, or from the absorbents being deficient in action, an accumulation of fluid takes place, either in the general cellular membrane or in the natural cavities of the body. Dropsy is either active or passive. Active or soute dropsy is owing to excessive action of the exhalents, in consequence of increased action of the heart; it comes on suddenly and tumultuously, and sometimes can scarcely be discriminated from inflammation with serous effusion. It is induced by various causes; as exposure to a cold moist atmosphere, particularly when the body is in a state of perspiration from active exercise or long exposure to heat. A labourer "has been digging (perhaps) in a wet ditch in winter time, and he pauses to take his meal; or he has been unloading a waggon, and rides home some miles in a heavy rain that wets him to the skin; or he has been mowing in the heat of summer, and lies down to sleep upon the damp grass."
The perspiration is suddenly checked, and in the course of a few hours he becomes universally anasarcous. Chronic or passive dropsies are occasioned by defective absorption, arising, in some measure perhaps, from an enfectled state of the absorbents, strictly and anatomically so called, but more frequently, chiefly, and in some cases entirely, from undue fulness of the veins; this venous repletion being produced almost always by some impediment to the free return of the blood to the heart; as tumours pressing on the great blood-vessels, ossification of the valves of the heart, &c. When the veins are distended to a certain degree with watery fluid, the entrance of more of the same fluid through their sides is impeded or prevented; and when the distension is still greater, the aqueous part of the blood may even pass in the other direction out of the vessel. The difference between active and passive dropsy is chiefly in the rate at which the collection augments; in the one case the liquid is rapidly ef fused in quantity much beyond the natural amount of exhalation, in the other the exhalation goes on as usual, but the fluid exhaled is not taken back again into the circulating vessels with sufficient facility. Wherever there is a shut sac, or wherever there is a loose and permeable areolar tissue, there we may have dropsy. There are certain parts, however, where it is more generally met with than in others, and is hence distinguished by particular names; thus, when in the head, hydrocephalus; in the chest, hydrothorax; in the belly, acities; in the arcolar tissue generally throughout the body, anasarca. When the arcolar tissue of a part becomes dropsical, it is said to be adematous. Cateris paribus, those parts of the body become the most loaded with serous fluid, of which the arcolar tissue is plentiful with serous num, to when the disease, the first and loose. In the treatment of this disease, the first object is to get rid of the preternatural accumulation of watery fluid; the second, to prevent its collecting again; for dropsy is generally a symptom or sequence of other disorders, and rarely a disease of itself. In active or febrile annasarca general blood-letting is often of great advantage, as it not only helps to relieve the congestion upon which the effusion depends, but it tends to abate the undue action of the heart; in other cases, however, blood-letting would be very interesting the content of the cases.

and symmetrical, hypogynous, with a quinary arrangement of their parts, which are persistent and imbricate; anthers extrorse; styles several; placentas parietal; frait capsular, I-celled, with loculicidal debiscence; seeds numerous; embryo small at the base of copious fleshy albumen. The Droseracea are found in almost all parts of the world with the exception of the Arctic regious. They possess slightly said and acrid properties. The typical gen, is Drosera, the sun-dew, the species of which are interesting, from the peculiar irritability of the hairs on their leaves. The plant commonly known as Venus's fly-trap is a The plant commonly known as Venus's fly-trap is a species of Dionese, another genus of this order, and exhibits in a most striking manner this irritability. (See Dronga.) Some of the sun-dews communicate a beautiful purple stain to the paper upon which they are dried, and also yield a yellow colour when treated with ammonis. They may, therefore, be expected to furnish valuable dyes, and should be examined with this view by the practical chemist.

DROWNING, drown'-ing (Dan, drugner, to drown), is sufficiation produced by the immersion of the body under water, or, according to some, by the exclusion of stmospheric air from the lungs by any liquid. The necessity of air to life is well known, and any exclusion of it, for even a few minutes, produces death. When a human being unable to swim falls into the water, if it is not of great depth, he first goes to the bottom; but on account of the air in the lungs rendering the specific gravity of the body lighter than the water, he immediately rises again to the surface. The efforts made by him to maintain himself at the surface diminish the quantity of air in the lungs, and he again sinks to the bottom, but soon rises again; and this alternate rising and sinking may occur several times in succession. The air which is expelled from the lungs is seen to rise to the surface in the form of bubbles, and with every expiration the specific gravity of the body is increased; the powers of sensation and voluntary motion rapidly diminish, and the body settles at the bottom. A feeble motion may still be perceived in the chest for a short time, but that, too, ceases, and death ensues. In drowning, death is effected by the impure condition of the blood. The impure or venous blood of the system is constantly being carried to the lungs, of the system is constantly being carried to the lungs, where, being brought into contact with the air, its impurities are carried off, and it is converted into pure or arterial blood. When, by any means, as in drowning, the lungs are shut out from communication with the external air, this operation cannot be carried on, impure instead of pure blood is carried through the system, the brain is immediately affected, sensation and volition ranially diminish, and at length cease. and volition rapidly diminish, and at length cease. The period during which life may continue in sub-mersion varies in different persons. In some instances bodies submerged but one minute have been found to be lifeless; and in many cases recovery hus taken place after a submersion of eight or ten minutes. Occasionally, mimation has been restored after a subplace after a submersion of eight or ten minutes. Occasionally, numation has been restored after a submotive or febrile anasarca general blood-letting is often of great advantage, as it not only helps to relieve the congestion upon which the effusion depends, but it tends to abate the undue action of the heart; in other cases, however, blood-letting would be very in jurious, from its enfectbing the patient; and as it frequently occurs from weakness, or living on poor or unwholesome food, the treatment must consist of a generous diet, with tonics. In general, the object is to augment the discharge of watery fluid from one or more of the secreting surfaces of the body; and it is often a matter of great micety to determine by what surface or channel this ought to be attempted. In some cases it is best to seek to promote this discharge by way of the kidneys; in others, by the nucous lining of the alimentary canal; in others, by the external skin. Sometimes great present relief is afforded to the patient by tapping; but it is generally only temporary, and can only sometimes be resorted to.

DROSEALORM, GROSEALORM, GROSEAL

Druids

on the face, with one arm under the forchead, so that any fluids may flow from the throat and nuth, and without loss of time,—I. To exist everpication; 4. turn the patient on his side and, a, apply anuff or other rritant to the nostrills; b, dash cold water on the face, previously rubbed briskly until it is warm. If there he no success, again lose no time, but, II. To smilate respiration; 5. replaces the patient on his face (when the tongs will then fall forward, and leave the entrance into the windpipe free); then, 6. turn the body gently, but completely, on the side and a little beyond (when inspiration will occur), and then on the face, making gentle pressure along the back, when capiration will take place, alternately. These measures must be reseated deliberately, efficiently, and perseveringly, fifteen times in the minute only. Meanwhile, III. To induce circulation and warmth, continuing these measures, 7, rub the limbs upwards with firm pressure on the face, with one arm under the forehead, so that measures, 7. rub the limbs upwords with firm pressure and with energy, using handkerchiefs, &c., for towels; & replace the patient's wet clothing by such other covering as can be instantly procured, each bystander supplying a coat, waistcoat, &c. "These rules," says Dr. Hall, "are founded on physiology; and whilst they comprise all that can be done immediately for the patient, available all apparents galvasium the warm. patient, cricule all apparatus, galvanism, the warm bath, &c., as useless, not to say injurious, especially the last of these, and all loss of time in removal, &c., as fatal."

Dave, drug (Fr. drogue), a term applied to those substances used in medicine sold by the druggist and compounded by apothecaries according to the prescriptions of physicians and surgeons. The proand compounded by apothecaries according to the prescriptions of physicians and surgeons. The professions of the chemist and of the druggist are mixed together in a very confused manner. This uncertainty has been caused principally by the rules established by the medical corporations, such as the College of Physicians, the College of Surgeons, and the Apothecaries Company. Acids, alkalies, oxides, and salts, which are used in large quantities, are manufactured on an extended scale in several parts of Great Britain. The term of chemist and druggist is, however, smally ambied to those oproms who retail and undersmally manifed to those oproms who retail and undersmally manifed to those oproms who retail and underusually applied to those persons who retail and understand the ohemicals which they purchase from other parties who make them on a large scale. A book has been lately published by Dr. Normandy, under the title of "The Commercial Handbook of Chemical Analysis:" of "The Commercial Handbook of Chemical Analysis: " this work is intended to afford aid in the detection of fraud in the manufacture of food, drugs, and chemicals. The subject upon which it treats is of especial importance to provincial druggists. The different substances are alphabetically arranged. The following remarks show the usefulness of such a work:—"Country druggists form a class of persons to whom this work would be very serviceable; for although there are, of course, highly creditable exceptions, particularly in great provincial towns, the bulk of whom are not distinguished for chemical, or even pharmaceutical knowledge. Few are expable of conducting an analysis or organic research, and they are frequently imposed upon by wholesale dealers, who send them damaged or spurious wholesale dealers, who send them damaged or spurious drugs, which, if administered in dangerous maladies, might induce agravation of disease, and very probably cause death." In 1558 a new medical act was passed, by which the new general council formed to carry out the provisions of the act is empowered "to cause to be published, under their direction, a book containing a list of medicines and compounds, and the manuer of preparing them, with the true weights and measures by which they are to be prepared and mixed, and conby which they are to be prepared and mines, and con-taining such other matters and things relating thereto as the general council shall think fit, to be called British Pharmacopoia; and the general council shall cause to be attered, amended, and republished such Pharmacopens as often as they shall feel necessary." In mercantile language, any commodity that lies on hand, or is not saleable, is called a drug.

nand, or is not sateable, is called a drug.

Drugger, drug-get (Fr.), a sort of cloth, of a coarse, flimey woollen texture, generally used for covering carpets, but in some parts of Great Britain used as an article of clething by families among the poorer classes.

Usually, it consists of a mixture of woollen and cotton, and in Scotland the insterial called drugget has generally the warp of a coarse flax, and is commonly striped blue and white.

Druggers / See Crawers and Theorems.

DECOGIST. (See CHEMIST AND DEUGGIST, PHAR-

MACRUTICAL SOCIETY OF GREAT BRITAIN, and UNITED SOCIETY OF CHEMISTS AND DEUGGISTS.)

DEUIDS, dru'-idz, a name given to the order of priests Drine, dru'-idz, name given to the order of priests which existed in ancient times among certain branches of the Celtic race, if not among all. Numerous derivations have been given of the name; but the most probable seems to be from the old Celtic word derouyd, from de, 'god,' and rouyd, 'speaking,' a participle of the verb rouyddim, 'to speak.' Various writers have endeavoured to establish a connection between the Druids and some of the other early heathen sects. Druids and some of the other early heathen sects. Some argue that the Druidical and Persian religious were identical; others regard them as connected with the Hindoos, others with the Egyptians, and so on. They only become known in history about the 1st century before Christ, and they were then chiefly found in Gaul and Britain. Julius Cæsar is the ancient author who has given the clearest and most minute account of them. According to him, they formed one of the two orders of rank and dignity in Gaul. They were engaged in things sacred, conducting the public and the private sacrifices, and interpreting all matters of religion. They were held in great honour an matters of reignon. They were head in great among the people, and a number of young men resorted to them for the purpose of instruction. They determined almost all controversies, public and private; decreed rewards and punishments; and if any one did not submit to their decision, they interdicted him from the sacrifices, which, among them, was the most heavy punishment, such persons being abunned by all, and deprived of all civil rights and privileges. Among the Druids there was one who possessed surreme authority Druids there was one who possessed supreme authority over them, who was either elected by the sullrages of over them, who was either elected by the sulfrages of the others, or, if pre-eminent in dignity among the rest, was at once elected. They assemble at a fixed period of the year, in a consecrated place in the terri-tories of the Carnutes, which is reckoned the central region of the whole of Gaul; and hither all who have region of the whole of crait; and influer all who have disputes assemble from every part, and submit to their decrees and determinations. They do not go to war or pay tribute like the rest, being exempted from military service, and having a dispensation in all matters. They are said to learn by heart a great number of verses; for they regard it unlawful to commit these to writing; and hence some remain in training for twenty years. In almost all other matters in their public and private transactions, they use Greek characters. Ones of their leading tenets is, "that souls do not become extinct, but pass after death from one body to another; and they think that men, by this tenet, are in a great degree excited to valour, the fear of death being dis-regarded. They likewise discuss and impart to the youth many things respecting the stars and their mo-tion; respecting the extent of the world and of our earth; respecting the nature of things; respecting the power and the majorty of the immortal gods. This institution is supposed to have come from Britain; and even now those who desire to gain a more accurate even now those who desire to gain a more accurate knowledge of that system, generally proceed thither for the purpose of studying it." As to the amount of knowledge possessed by the Druids, we have little means of determining. They unquestionably, however, possessed some knowledge of the beavenly bodies beyond what simply pertained to the regulation of their religious festivals, inasmuch as they computed the year by lunations, which supposes an acquairtance also with the solar year; and various relics have been found in Ireland, among Druidioal remains, which are thought to land, among Druidical remains, which are thought to be astronomical instruments designed to show the phases of the moon. At the same time, there was not a little of astrology, divination, and magic mixed np with their purer science. In their dootrine of medicine particularly, there was far more of superstition than of knowledge. To a great many plants they attributed a sacred mystic character. The oak was especially regarded as sacred among them, and in the out-groves they frequently performed their rites, deriving, according to some their name from the oak. Most cording to some, their name from the oak. cording to some, their name from the oak. Most sacred of all, however, was the mistletoes, which they esteemed so an antidote to all poisons, a cure for all diseases. It was gathered at certain seasons, with the most formal and pompous ceremonies. According to Pliny, as soon as it was discovered upon the oak, the Druds collected in crowds about the tree; a priest in white vestments ascended, and, with a knife of gold,

Dry-rot

out the mistletoe, which was received by another standing on the ground; sacrifices were offered up, and the day spent in rejoicings. These were certain other plants which were regarded as potent remedies for various diseases, and were servied about as charms, as well as amber beads, which the Druids manufactified for warriors in battle, and which are still found in their tombs. A still more powerful taliuman was, according to Pliny, the serpents egg. It was formed, he says, by the poisonous spittle of a great many serpents twined together. It was gathered at moonlight, and afterwards worn in the bosom. Their profounder seremonies, those which they celebrated in the depths of the oak forests or of scolladed caves, are known to us only through the vaguest traditions, and in the stupendous but displated stone mountents which still exist in some parts of France and Britain. It is said pendous but dispidisted stone monuments which still exist in some parts of France and Britain. It is said that human sacrifices were frequently offered up upon their slars. They consisted of three distinct classes,—the bards, the vates or prophets, and the priests proper. The bards were poets, not only of a religious, but also of a martial and satirical class. The vates were the diviners or revealers of the future, who were charged with the conduct of sacrifices and other exchanged with the conduct of sacrifices and other external ceremonies, and who stood as mediators or interpreters between the people and the higher order of priests. These dwelt in the depths of the oak forests, of priests. These dwelt in the depths of the oak forests, cultivating the more secret and mystic doctriner of their faith. They exercised judicial functions, and were resorted to in great numbers by the youth for instruction. When Gaul was subdued by the Romans, the Druidical religion gradually retired before the classic heathenism, and, step by step, withdrew at first into Armorica, and then into Great Britain, where, in the time of Nero, it was attacked and mostly suppressed. It lingered as a public worship longest in the sland of Anglesca, whence it was finally driven out by the Roman troops, amid a great deal of alaughter. Nevertheless it continued, as a superstitious belief, to hold sway for many years thereafter over the minds of the Celtic tribes and their descendants.

Datus, draw (Du. trom, troomed, Ger. troomed, Dan. fremme), a musical instrument of percussion, supposed to be of Oriental invention, and said to have been introduced into Western Europe by either the

been introduced into Western Europe by either the Moors or the Arabians. Of drums we have three kinds they are as follows:—1. The base or Turkish drum, which is the largest, and consists of a hollow cylinder of oak covered at each end with vellum fastened to the rim in such a manner that it may be tightened or loosened ad libitum by means of small cords or brace loosened at libitum by means of small cords or braces exted upon by sliding knots of leather. 2. The double or kettle drum.— An instrument made of copper, nearly hemispherical, covered with a strong head of calf-skin, and standing upon three iron legs. They are always in pairs, and are tuned by screws,—one to the keysote of the piece accompanied, and the other a fourth below. 3. The side-drum.—This is constructed like the first, but generally has a breas cylinder, and is much smaller. Within the last six years great improvements have been made in the manufacture of side-drums by Messrs. Mey, Rudall, and Co., Charing-cross, London; and, since 1858, our infantry have side-drums by Mesers. Key, Rudall, and Co., Charing-cross, London; and, since 1858, our infantry have been supplied with these drums by the above-mentioned makers. They weigh three pounds less than the old fines, are much smaller, of a superior tone, and tuned by screws instead of the old straps and ropes. There has also been a drum of this kind invented without a cylinder, resembling two tambourines joined at a short distance apart by small bars of iron, with their concavi-ties facing each other.

Danwellan Cours-Mastal, the name given to a

ties facing each other.

DEUM-HEAD COURS-MASSTAL, the name given to a conneil of officers convoked in haste when on active service, to punish or pass sentence of death on any soldier who has committed an offence which requires to be dealt with in a summary manner. The big drum was used as a table, round which the officers composing the council assembled; whence the name, which is now applied to any court-martial held in haste.

Deut-Major, the principal drummer in a regiment, who beats the big drum, and teaches and has the general misagement of the other drummers. He also receives orders from the officer in command respecting the drummers, and the beats to be given at any appointed time.

DRUMMER, drum 'mer, any man or boy in a regiment who bests the drum, and in this manner gives various signals to the troops. (See Braz or DRUM.) Signals are given to light infantry by bugiers instead of drummers. The drummer has to perform the unpleasant duty of flogging any soldier who may be ordered to receive a certain number of lashes as a pumishment. The drummers stand immediately before the privates on the musterwich. on the muster roll.

On the muster-rus.

Drummer, a species of coackroach found in the West Indies, and so named from its habit of keeping up a continual knocking noise during the night. They are said to attack people when salesep; and this is probable correct since they have been seen to pray on the

minute in proportion to its wonderful brilliancy.

DRUTACEE. (See ANYGDALEE.)

DRUTA, drop (Lat. drupe), in Bot., a superior onecelled, one or two seeded, indehiscent fruit, having a
fleshy or pulpy sarcocarp (middle layer), and a hard
or bony endocarp (inner layer). The perioarp, or
complete envelope of tha seed, is separable into its
component parts,—namely, epicarp (orternal layer),
sarcocarp, and endocarp. The drupe is commonly
called a stone-fruit. Examples occur in the peach,
apricot, plum, and cherry. The trut of the almond presents all the characters of a drupe, except that the sarcocarp is of a toughish nature, instead of being

sarcocarp is of a toughish nature, instead of being succulent. A number of drupes aggregated together on a common receptacle, as in the raspberry, form collectively a kind of eterio (which see).

DRYING OILS, dri-ing oils (Sax. dri, dry).—Oils are divided into drying and non-drying oils, according as they become solid or remain liquid by the absorption of the oxygen of the air. The principal drying oils are linseed, walnut, poppy, hemp, cod-liver, and aperm. Those belonging to the latter class are olive, almond, rape, colra, and many animal oils. The uses of the former for paint, and of the latter for illuminating purposes, are instances of their opposite properties being taken advantage of.

Dry-form, in Eng., a sharp, fine-pointed etching-

DNY-POINT, in Eng., a sharp, fine-pointed etching-needle, used to cut fine lines in a copper or steel plate without biting them in with soid. Work produced in this manner is very delicate as well as durable.

whout biting them in with said. Work produced in this manner is very delicate as well as durable.

DRY-ROY, the name given to the decay of timber, proceeding from the fermentation of sap that is left in the wood, and which is brought about by the influence of warmth, combined with a certain degree of moisture and the want of proper ventilation. It appears in timber that has not been properly eassoned, or which has been cut in the spring of the year, when the sap is rising, as in the case of oak-trees, which are cut at this time for the sake of the bark. When the sap has fermented, the vegetation of fungi follows, which spreads through the wood, destroying the fibres to such an extent that they crumble into dust under any slight pressure. To prevent dry-rot in timber, it is necessary that it should be well seasoned, and that the air should at all times have free access to it. Various methods have been adopted for filling the pores of the wood with some solution, to reader it proof against destruction by dry-rot, among which may be mentioned Sir William Burnett's process, by which the wood is seaked in a solution of chloride of sino, and that of Kyan, by which the pores of the timber are filled with a solution of heloride of sino, and that of Kyan, by which the pores of the timber are filled with a solution of heloride of sino, and that of Kyan, by which the pores of the timber are filled with a solution of heloride of sino, and that of Kyan, by which the pores of the timber are filled with a solution of heloride of sino, and that of Kyan, by which the pores of the sino page of the sino page and the sino page and the sino of the chloride of mercury, forced into them by the sir-pump.

DEFERENCIANCES AND ASSESSED ASSESSED AS AS In 1851 a royal commission was appointed to inquire into the state, discipline, studies, and revenues, of the nniversity; and in consequence of their report, various alterations were effected in the statutes. In the alterations were effected in the statutes. In the charter of feundation the queen nominated one provost, three fellows, and three scholars, in the name of the statute of t more, to constitute, with their successors, for ever, a body corporate and politic. The number of the cor-poration has been increased from time to time, and at present consists of a provost, seven senior and twentyseven junior fellows, and seventy scholars. The pro-vost and senior fellows form the board of management, and power is given to them to alter, amend, or repeal all laws, rules, or by-laws, to make new laws and rules from time to time; such new laws or alterations, however, not to have force or be binding upon the university until approved of by the senate or congregation. ever, not to have force or be binding upon the university until approved of by the senate or congregation. The senate consists of the chancellor, or, in his absence, of the vice-chancellor or pro-vice-chancellor for the time being, and unch doctors or masters as shall are and keep their names on the books of the college. The caput of the senate is a council, consisting of the chancellor or vice-chancellor, the provest (or, in his absence, the vice-provest), and the senior master non-regent, who is elected by the senate. Every green cover, more especially those of the preceding year. Terms may be kept in two ways.—by attendance upon mences with an examination of the studies previously one over, more especially those of the preceding year. Terms may be kept in two ways.—by attendance upon the lectures or by merely passing the term commences are passing the term commences and the senior and number of the caput has the caput before it can be proposed to the respictive voice. The provest, or head of the college, is appointed by the Crown, and must be in boly orders, and a solution of the senior, and therefore an elegative voice. The provest, or head of the college, is appointed by the Crown, and must be in boly orders, and a solution of the caput in the city; law, engineering, and medicine, however, are continued by the Crown, and must be in boly orders, and attend lectures are promoted from the juniors in the order of saniority. The examination comprises mathematics, mentals, inserted and morel sciences, physics, classics, the leftway are promoted from the juniors in the order of saniority. The examination comprises mathematics and experimental and experimental, classically an experimental and experimental, classically an experimental and experimental.

# Dublin University

benefices at the disposal of the college. The law binding them to calibery was abolished in 1286. They must be members of the English dearch, and are all bound to enter into pricate orders except five a madisus, two jurists juris civilie, and two jurists juris anglish. The average annual moons of a serior follow from various acuroes is naually from £1,200 to £1,500; of a invitor follow membrals from this past of the from various sources is usually from \$1,300 to \$1,560; of a junior foliow, principally from thition, about \$300. The income of the provest is about \$2,560 per annum. The scholars are chosen from among the undergraduates fatter examination; one close of scholarships being fog classical, another for scientific merit. Scholarships are open to all students being or becoming mambers of the established church, and age tenable until the holder is entitled to the degree of thatter of arts. Nichelarships their commonstrate of streams arts. Nichelarships their commonstrate of streams and meaniers of the established cancer, and are venante until the holder is entitled to the degree of thester of arts. Scholarshave their commonsfree of expense, and their rooms for half the charge paid by other students; they pay half-feet, but are exempted from college charges or decrements, and receive from the college charges or decrements, and receive from the college charges or decrements, and receive from the college charges are also non-foundation scholarships, founded in 1854, open non-foundation scholarships, founded in 1854, open to students of all religious denominations. Their emoluments and tenure of office are the same as those of the other scholars; but, as their name imports, they are not members of the corporation, and do not enjoy the univarsity franchise. There are four grades of students:—1. Noblemen, sons of noblemen, and baronets, who enjoy certain privileges, the two first being entitled to the degree of B.A. per speciales grations; 2. fellow-commoners, who have the privilege of dining at the fellows' table, and who are entitled to the degree of B.A. with one term exemination less than pensioners; 3, pensioners, who form the great body of the students; 4 sizars, who are students of limited means, and have their commons free of expense, and are exand have their commons free of expense, and are ex-empted from annual fees. Sizars are admitted annually by examination, and the number is limited to thirty. Each rank has a dress peculiar to itself. The mode admission into the university is by an examination held once in every month (except February, August, and September); those in July, October, and November being public, the rest private. The subjects of exam-ination embrace Latin and English composition, arithmetic, algebra (the first four rules and fractiona), English history, modern geography, and two Greek and Latin books. Besides the honour of "firstplace" at entrance, prize of the value of Me and E2 are awarded for excellence in special branches of the entrance course, and ske for Hebrew. Each student at entrance must select one of the innior fellows who act as tutors to be his instructor and guardian of his interests during his academic carear. Undergraduates of the first and second year are junior and senior freshmen; of the third and fourth, junior and senior resamen; of the third and fourth, junior and senior sophiators. The course for all students is.—first year, mathematics, Greek, Latin; second, mathematics, logic, and metaphysics, Greek, Latin; third, logic and metaphysics, physics (mathematical and experimental), classics. An extended course is prescribed for those

#### Drong

26. St., the sizers being exempt. These do not include recess and commons. To encourage meritorious sindents, and to make some provision for those who, after graduation, desire to devote themselves to learning, fourteen studentships were standed by royal statute in 1859. These are open to candidates of all siligious denominations, and are temable for a period not exceeding seven years. The manay, as fixed by the provent and senior fellows, is not to exceed \$100 per annum. A school of engineering was established in the university in 1853, with the view of combining the theoretical and practical instruction necessary for the processes a very complete staff of professors, who represent negaty all branches of summa knowledge. The total number of students on the college books, under the degree of M.A., was in the year 1871 as follows:—Scholars of the house, 69; non-foundation scholars, 10; fellow-commoners, 37; pensioners, 1,132; sizars and ex-sizary, the M.E. Dub. University Calendar, 1871.

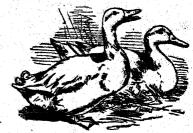

Dygar, bub-ut (last ducates, duchy), a gold coin very much used throughout the currency of Europe. It derives its mane from the legend found on the first pieces of the kind, which were coined in Sicily during the 12th century. The legend runs: \$11 tiel; Christe, dates, quem tu regis, Duactes, ! Let that duchy

during the 12th ventury. The legend runs: Sit fibi, Christs, datus, quem tu regis, Duactus, 'Let that duchy be thine, O Christ, which thou rulest.' After the 12th ventury the issue of ducats increased largely in Italy: Venetian ducats were called Lecchini, from Leoca, where they were coined. In 1509, Germany adopted the ducat into the consequence of the ducate into the consequence. where they were coined. In 1859, Germany adopted the ducat into the currency, and shortly afterwards its use spread over the whole of the north of Europe. The ducat varies in quality and weight. The ordinary ducat, which is current in Russia, Austria, Hamburg, &c., weighs 54 grains troy, and has a value of 9s. 4d, sterling. Many German states no longer issue ducats. The Italian ducat is of less value than the translational that Versiting ducat heirs, which that mentioned, the Venetian ducat being valued at the sterling. The Spanish ducat is called ducado, but is generally called a dollar: its value in English money is 4s. 2d., and it is made of silver.

DUCES TROUM, du'-seez te'-kum (Lat., you will bring with you), in Law, is a writ commanding one to appear at a certain day in the court of Chancery and to bring with him some evidences or other things which the court would view. A party in any cause or matter depending in the court of Chancery may by subpona ducing focus require the attendance of any winces before the examiner, and is entitled to the production of any deed, paper, or writing in his possession, custody, or power. If the court, however, does not think it probable that the documents will be evidence

#### Duck

and even now our fen counties are patronised by them in anoh wast numbers as to been the London market fully supplied in the season. The extreme wastiness of these birds renders necessary much patience and ingenity in obtaining large quantities of them. They fly at a considerable height in the six, in the shape of a wedge or triengle, before they slight on any spot, they take several wheels in the air, as though to reconnecte, and then descend with extreme precusion. When at rest on the water, they take bare to been at a considerable distance from the afters, and when they compose themselves for eleep, some of the company are always awake to keep guard, and to imprise the compose themselves for elemp, some of the company are always swake to keep guard, and to apprise the remainder of the approach of danger. They are much more active by night than by day. The wild duck usually makes her next amongst the tail grass or rushes skirting the water; but instances have occurred of the birds building in trees. "In Susser, the nest of a mallard was found in an oak-tree five and-twenty

AYLESBURY DUCKS.

feet from the ground; the old bird was sitting upon nine eggs supported on some small twigs laid crosswise. In Derbyshire a gerileman's gamekeeper observed a wild duck fly out of a large oak in which the year previous had been a hawk s nest. On examination she was found to have completely repaired the old nest she was found to have completely repaired the old nest and to have high therein two eggs. Another instance occurred at Madely, in Staffordaire. In this case the wild duck took possession of a fook's nest near the top of an oak. The drake was also seen to perch on a bough near her, and occasionally in her absence to sit in the nest."—(Staniey's History of Birds.) The food of the duck consists of worms, molluses, and aquatic insects, which they separate from the mud by the agency of lamelles at the margins of the bill. Inspeaking of the malliard as the type of the timeduck, Mr. Tarrell observes, concerning their leading characteristics — Externally they exhibit considerable length of neak; the wings are also long, reaching to the end of the tail; the tarsi somewhat round; the hind toe free, or having no pondent lobe. In habits they may be stated generally as frequenting fresh water, but passing much of their time on land, feeding in ditches and about the shallow edges of pools, on aquatic plants. think it probable that the documents will be evidence between the parties, the court will not compet the comments of a third party to be produced.

DUGHA HERF. (See MECHANDARME).

DUGHA, dutables (Fr. dutable), a term applied to the courtery or dominious of a duke; as the dutably of Langaster. The court of the duciny of Langaster in Externally they exhibit considerable length of the results which the name of dutk is generally extended is characterized by greater breasth of bill then either which the name of dutk is generally extended is characterized by greater breasth of bill then either the whilst that of both swans and getes is in frest part vegetable. A well-known brimple of this family is the wild duck, or common maliard (Lang Berkell), the conjunction of all the countries of Europe, but abounds especially in the northern parts. It is heavy two feet in length, three feet in extent of wings, and weights about three pounds. The bill is of a greenish yellow colour; the head and upper part of the neck of a closey green, terminated in the middle of the neck by a white colour. The scapings for white colour; the best is brown, and the rump black, shaded with green. The lower part of the neck of a white colour. The scapings for white solder. The isometract of marsh hand in the proper places. The common status of the neck by a white older. The scapings for white colours the best in extent of an extent of an extent of the neck by a white colour. T

#### Duck

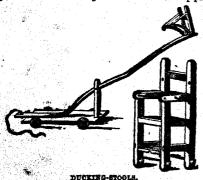

with one mate, but takes the control of an entire troop of hems. Whatever its species may be, the tame duck is a desirable bird to have in a poultry-yeard. Nor is water indispensable to its existence; "so far from it, instead of being absolutely necessary, it is often injurious to the young; in fact, they should never be allowed to swim till more than a month old. Instead of allowing young ducks to go out in the morning to est slugs and worms, they should be kept up, since this food, notwithstanding their partiality for it, is injurious."—(Stanley.) They lay a great number of eggs, require very little attention, and, with respect to ducklings, they may be easily fattened in the course of a month with any kind of pulse, or grain and water. (See Dacor.)

O's Boots, with any aim of pune, or grain and excellent (See Dacot.)

Duck (from Swedish duk, a cloth), a sort of plain heavy linen, highly glazed, and of coarse texture. It is much used for making the smock frocks worn by the agricultural labourers in England, and also for the many different in course and iron

roogh shirts worn by workmen in copper and iron smelting-works and forges.

DUCKELLA, ORNITHOERINGUES, or PLATTPUS, dubi-dilys gen. of mammalis, ord. Monotremata. Only one species is fully ascertained (O. paradosus, or pasatious), generally known as the water-mole in the Australian colonies. The active length of the suited including generally known as colonies. The entire length of the snimal, including bill and tail, is about two feet; body long and compressed, and thickly covered with very glossy hair, at the roots of which is a layer of waterproof felt-like material. The head is round and small, eyes small and bright, no external ear, and instead of the muzzle, mouth, and teeth of an ordinary quadruped, the creature is furnished with a bill like that of a duck (but have after it proportion), and possessing small transverse broader in proportion), and possessing small transverse lamine like the duck's bill. The legs are short; the fore feet have each five toes, with strong burrowing claws and a connecting membrane for swimming. The hind feet are likewise webbed, but the web does not extend beyond the base of the claws. The tail is strong, extend beyond the base of the claws. The tail is strong, broad, and flattened, about half as long as the body, covered with longer and coareer hairs, and nearly naked on its under surface. It lives chiefly in the water, and, like the duck, seeks its food among the mud. Its burrowing powers are said to exceed those of any other animal, fifty feet being no very uncommon length for it to run. It is wary and active, and by no means easily shot. Its voice resembles that of a young puppy. DUCKING-STOOL, dak'-ing stool (Ang.-Sax.), an apparatus of varied form, used formerly in Britain for punishing scolding wives. One of the most ordinary forms of the ducking-stool was the following:—A strong wooden chair was fastened to the end of a long beam, which worked like a see-saw on a pivot, on a post bedded into the edge of a dam or the deep part

The woman was placed in the chair with of a river. The woman was placed in the chair with her arms drawn backwards; a bar was placed across her back and inside her elbows, while another bar held her opright; in this uncomfortable position she was securely tied with cords. The persons appointed to carry out the punishment, by raising their end of the beam, caused the unfortunate outprit to go over head in the water. By pushing down their end 708

## Duelling

with a chain, she was once more brought to the surface; and the ducking was repeated, according to the enormity of her offence. Sometimes the ducking stool was combined with a tumbrel. A ducking stool of this description was in use at Leominster up to the year 1809; the beam was 23 feet in length. The practice of using the ducking-stool commenced in the 15th century, but had almost died out by the close of the 18th. The cucking-stool, often confounded with the descript stool was different tunishment; it the ducking stool, was a different punishment; it was used unreservedly for men and women, who were fixed in a stool at their own doors, to be pelted and hooted

at by the mob.

Ducr, dukt (Lat. duco, I lead or conduct), denotes generally any tube or canal by which a fluid is conducted or conveyed. It is more particularly used in Auat. to denote the vessels which convey the fluids in

animal bodies.

DUCT, in Bot. (See VESSEL.)

DUCT, in Bot. (See VESSEL.)
DUCT, ALIMENTARY. (See ALIMENTARY CANAL.)
DUCT, ALIMENTARY. (See ALIMENTARY CANAL.)
DUCTLITY, duk-till-e-fe (Lat. ductible, from duco, I lead, draw), the power possessed by certain bodies, and especially the metals, in virtue of which they are capable of being drawn out in length, while their diameter is diminished, without fracture or separation. Among the metals it may be called the property of being able to be drawn out into wires. The order of the metals which are ductile is almost similar to the order of those which are malleable; it is as follows:—Gold, silver, platinum, iron, copper, zino, tin, lead, nickel, palladium, cadmium. Platinum wire has been produced only acont of the indiameter. Glass produced only 1000pth of an inch in diameter. Glass is exceedingly ductile at a high temperature. The property is also possessed by other substances; such as gums, glues, resins, &c., when softened by moisture or heat.

DUELTING, du'-el·ling (Lat. duellum, Fr. duel), a combat between two persons, at a time and place specified in a challenge sent by one of the parties to the other. Duels usually arise out of private quarrels, and the general practice is for the party insulted to send a friend to demand an apology. If he refuses, he is requested to name his friend; and the two friends, is requested to name his friend; and the two friends, or seconds as they are called, arrange the preliminaries for the combat. They also choose the ground, regulate the mode of fighting, place the weapons in the combatants' hands, and enforce compliance with the rules which they have decided upon. Although the duel is now of very rare occurrence, it is comparatively a modern institution. is comparatively a modern institution. Among the ancient Greeks and Romans no such practice existed, and the word duellum meant a war between the ancient offers and homes in such passes, existed, and the word duellum meant a war between two nations. Afterwards, under the belief that God would interfere miraculously in behalf of the innocent against the guilty, judicial disputes were decided throughout Europe by trial by battle. (See Battle, or Battle.) Probably the duel originated in a belief in the same principle. It seems to have had its origin among the Germanic nations. Louis le Débonnaire was the first French king whe permitted disputants to resort to arms. Henry II. prohibited duelling, on account of a combat between his friend Francis de la Chastaignerie and Guy Chabot de Jarnac, in which the latter was slain. The practice of duelling, however, still continued. Francis I openly encouraged it, and set an example by challenging Charles V. Several ineffectual attempts were made to put down the practice; but to such an extent was it encouraged it, and set an example by challenging Charles V. Several ineffectual attempts were made to put down the practice; but to such an extent was it carried on during the sovereignty of Henry IV., that in the first eighteen years of his reign 4,000 gentlemen lost their lives in duels. Henry was compelled by popular feeling to endeavour to abolish the outsom by adding death, in extreme cases, to the penalties then in force. He, however, did not look with an unfavourable eye upon duelling; somequently, although very unlawful, it became very fashionable. During the reign of Louis XIII duelling became so prevalent that it was said in Paris that no Frenchman was worth looking at unless he had killed his man. Although duelling was so common, the law against it was carried out with great rigour, sud several noblemen and gentlemen of high renown were bebeaded for pernisting in fighting. During Louis XIV's reign, duels of three, four, and five a side were common; but the king at last enforced the laws with such firmness that, for the time, duelling

was almost abolished. Duelling appears to have been introduced into England about the time of the Norman conquest; but it was principally in its public or judicial form. Private duelling was very prevalent in the reign of Queen Elizabeth. It declined public or judicial form. Private dueting was very prevalent in the reign of Queen Elisabeth. It declined during the Commonwealth, but broke out again in the reign of Charles II. During the reign of William III. attempts were made to abolish duelling; and in 1712 - till was introduced into parliament, but 1712 a bill was introduced into parliament, but was thrown out, notwithstanding that its objects was thrown out, notwithstanding that its objects had been strongly advocated in Queen Anne's speech. After the wearing of swords was abandoned, dueling diminished for a time; but the pistol soon began to take the place of that weapon. After a time, chance took the place of skill, and ghastly, albeit absurd, duels were fought at two or three paces, one pistol being loaded and the other not. This sort of duelling seemed to reach its climar when the disputants made choice by lot between two pills, one made of bread and the other containing poison. From the woint duelling declined, and has quite fallen into made of bread and the other containing possible. From this point duelling declined, and has quite fallen into disrepute; in this country, indeed, it may be said to be abolished. By the laws of England, any man killing another in a duel, however fair it may have been, is sonsidered guilty of murder. Whilst it was not looked about marourably by the public, no jury could be found who would convict any one charged; but the case would probably be different at the present day. The duels among the German students were merely fencing-matches with sharp weapons; and although some ugly cuts in the face were given and received. they were never absolutely dangerous, as armed seconds were always on the alert to prevent any serious wounds. Several stringent additions on the subject of duelling were added to the Articles of War in this country in 1844 by the commander of the forces. Partly through these, but more particularly through the increasing improvement of English society, duel-

ling has ceased to be an institution of this country.

DUENNA du-en'-nā (Span. dueña), the title applied to the chief lady in waiting upon the queen of Spain. In a more restricted sense, the termed is used to designate a person holding a middle position between and companion, and appointed to take charge of those young ladies who are members of Spanish or Portuguese families.

DUET, du-et' (Ital. duetto), in Mus., a two-part com-position, either vocal or instrumental, with or without a bass and accompaniments. To form a good duet, the execution should be pretty equally distributed between the two parts; the melodies so connected, intermingled, and dependent on each other, as to be entirely inseparable, but at the same time perfectly related and concinnous when heard together. Although combined by the situation of the harmony, the parts are not necessarily similar in their motion; on the contrary, it is by varying and giving them contrary directions, that the best effects are produced.

Dugono, du'-gong (Halicore Dugong), a marine animal belonging to the herbivorous cetaces. In general form it much resembles the manates. Its length varies from twelve to twenty feet. It feeds on length varies from tweive to twenty rest. It leeds on the alga which grow on submarine rocks in shallow seas. Its affection for its young is remarkable; and if the latter can be surprised and captured, the mother may be easily taken. Its flesh is caten, and said to resemble coarse beef in texture and flavour. It is found among the islands of the Indian archipelago. Rüppell asserts that it was with the skin of the dugong that the Israelites were ordered to veil the tabernacle.

Israelites were ordered to veil the tabernacle.

DUGUERIA, du-gu-e'-sk-d, in Bot., a gen. of plants belonging to the nat. ord. dnonaces. The only interesting species is D. quitarensis, a native of Guiana, which furnishes the atrong elastic wood called lancewood. This is chiefly use by coach-makers.

DUER, dute (Lat. due, a leader, a general; Fr. duc, Ital. duca), an honorary title given in England to noblemen of the highest rank. The term is first used in history in Gen. XIXVI. 15, with reference to the grandsons of Esan, and probably signifies their position as the heads or founders of families or tribes, as it that early period. It wasseapplied as an especial title of rank to the military governors of provinces of the Roman empire about the year 325, in the reign of 709

Constantine the Great, when they ceased to exercise the civil functions which had hitherto formed a part of the duties of the Roman guretnors or proountators. There were from thirty to forty of these duces or dakes, ten of whom were partimistry disfinguished by the appellation of comes, or companion, in allusion to the closer relationship into which they were brought to the emperor, by virtue of the high dignity with which they had been invested. The title comes in late ages became "count," and then implied a rank subordinate to that of duke, although it had previously been superior to it. (See Court.) The early Roman counts and dukes were distinguished by wearing a golden baldrick or band, and they received considerable emoluments from the state, to enable them to support their dignity in a becoming manner. Their to support their dignity in a becoming manner. Their to support their dignity in a becoming manner. Their power was entirely restricted to their military command, other officers being appointed to collect the revenues and administer justice. The title of duke was preserved in snoceeding ages, and for the most part applied to military commanders of high rank, by the northern tribes, who asserted their supremacy over the south of Europe in the latter days of the Roman empire. At the time of the conquest it was account of the conquest it was a triant to restrain the super shearth and linkly given to persons exercising almost absolute and kingly power over large tracts of territory called dukedoms, acknowledging the superiority of the monarch, of whom they were supposed to hold their lands by fendal tenure, by some slight and cocasional act of homage. (See Faunt Swarzak). It was, however, no uncommon thing for the duke to enter the lists with his feudal lord on very slight grounds of offence, and successfully hold his own against him. Such were the dukes of Normandy, Gascony, Aquitaine, and Bur-gundy. Their dominions and titles were hereditary in all cases. The title is applied even in the present day to the soversigns of many notity German States long. to the sovereigns of many petry German states, sometimes with the prefix of "grand" or "arch;" as the grand-duke of Baden, the duke of Brunswick, &c. In our own country the Norman and Plantagenet kinga assumed the title by virtue of their continental possessions accurated by interience on marriage. Into it was sions, acquired by inheritance or marriage; but it was-first conferred as an honorary distinction by Edward III. on his son, Edward the Black Prince, whom he created duke of Cornwall in 1335; since which time the title has always belonged to the prince of Wales for title has always belonged to the prince of Wales for the time being, by prescriptive right. For some time after this the title was strictly confined to princes of the blood royal, or to those who were very nearly allied to the royal family; but shout 1450 the dignity was extended to the Staffords, Beauchamps, and other families, besides those who could claim close kindred with the sovereign. The majority of Roglish dukedoms were conferred in the reigns of William III. and Mary, Anne, and George I; but since the death of that monarch comparatively few instances here occurred of the creation of a dukedom, that of Wellington, created in 1814, being most worthy of notice, and curred of the creation of a dukedom, that of Wellington, created in 1814, being most worthy of notice, and most honourably earned. There are at present twenty-eight dukes of the United Kingdom, the duke of Cambridge, a duke of the blood royal, being excepted, of whom twenty are English, seven Scotch, and one, the duke of Leinster, Irish. The duke of Norfolk is the premier or senior duke of England, by priority of creation; and the duke of Hamilton, the premier duke of Rogland. duke of Scotland.

DUES OF EXERTE'S DAUGHREE, an instrument of torture resembling the rack in construction. It is said to have been invented during the reign of Henry VI., by the dukes of Exeter and Sussex. According to Blackstone, it was never put into use. It was at one time exhibited along with other instruments of torture in the Tower of London.

in the Tower of London.

Duke of York's School, the name commonly given to the Royal Military Asylum at Chelseaf established by the duke of York (who, by this and other sots, earned the sppellation of the "soldier's friend") at the commencement of the present century, for the orphan children of soldiers. The expenses of the institution are met by a public grant made for the purpose, which always forms a part of the annual army estimates. The boys are admitted as vacanies happen to occur, and are chosen by the board of management from the numerous applicants who are candidates for the benefits of the charity. On quitting

#### Dukumara

the explain the boys generally enter the erroy; but if they do not wish to do so, they are apprenticed to some trade. There was also a subsol for the orphan daughters of suddiers at Cheises; but this has long since been given up, owing to the missional destroisme of those who had been educated there. It appears, however, to be unjust that the should excited the daughters of suddiers who have deal in the saction of their soundry from participating in the advantages provided by the state for their some.

Dynamana. Also hereafter h

Depositions, deliverment (feel, delemello, from delement), a manifest instrument, most probably of the wind-species, used amongst the moient Hebrows. Its enter form is unknown.

BULSE. (See BEODOMENTA.)

FULSE. (See BEODOMENTA.)

Towners. du/-ij, was founded at Dul DULMING COLLEGE, Sul'-ij, was founded at Dul-wick, a suburb of London, about 41 miles S.S.E. of St. Faul's, by Edward Alleyn, an actor, in 1612. The pregnate revenues only amounted to £300, but they now exceed £12,000, and maintain a master, four fellows, exceed 222,000, and maintain a master, story lenows, six poor six poor sixters, twelve poor scholars, and thirty out-members. The building was recently regained and much improved, under the superintendence of the late Sir C. Barry. It has a picture-gallery containing some fine paintings, chiefly by the old masters, and sequesthed to the college by Sir F. Burgeois,

DUMB. (See DEAR AND DUMB.)

DUMB-BELLS, duran'. bells, two weights, generally made in the form represented in the en-graving, used for pur-poses of exercise. They are made of various weights, varying from about 8lb. to 28 lb. The centre bar, which is often covered with leather, is grasped in the hand.

DUNCTAD, TEB, dun'-sho-dd, a satire originally written in three books, by Alexander Pope, in 1728; he, howperiod Pope had suffered from the attacks of a number of critics and detractors, who not only denied his genies, but attributed to him the basest and meanest of motives. Unable to bear these attacks any longer estimathy, and stong to the quick, he determined to attribe out in every direction at his antagonists, and the Dimeniad was the method by which he achieved his said. Oritics, authors, publishers, at hoc genus comme, winsed and howled as the stinging lash of his satire fell it light and left among them, and wherever it fell it leave blood. He recriminated, and chartised in teres epigerum and not over-debeste sairs, every one by whom he thought he had been aggrieved, and immortalised his autagonists as he demolished them. Even now, although all the dramatic persons are passed away from period Pope had suffered from the attacks of a number although all the dramatic persons are passed away from the mene, the Dunciad can still be read with interest as a model of polished verse and keen pungent sature.

Dumms, or Downson verse and seen pungest satirs.
Dumms, or Downson, dunce (Cett, duns, h. hill, whence Fridmes, Ger. dunes, Du. duynen), the name given to low and simust bereven hills of sand of great breadth, that extend along the coast of Holand, Belgium; and the northwar departments of France, and serve to protect northern departments of France, and serve to protect the factile land within them from the insade of the coses. They have been formed by the wind blowing great questities at and inland whenever it set dear and a day after its askinding on an extensive a subcess. Surrey; and the North and South Downs, in Kent and

DUNG-REFILE, duny-by-fi (Ang-Seat), the most of certain of the Scarabuides, living, for the most spart on or in the dung of other sminals; They see seion on or in the dung of other animals. They are solventifically known as Coprophagi (Gr., dung bestie). For the most part they are black, or black and brown, and some few are adorned with brillians anshills coloure. To this section belongs the secret bestle of the Egyptians, the Scewaless ascer of Linnesse: it is about an inch long, and of a black colour. This species is not only found in Egypt, but is met with in the south of Spain, France, and Itsly, and, as well as other species of the group to which it belongs, incloses its eggs in a ball of extrement, which it forms by rolling the substance by means of its hind-legs. The size of the ball, when completed, is much larger than the insect, being sometimes as much as an inch and a half in diameter. sometimes as much as an inch and a half in diameter. The dor, or shard-born beetle (Geotraper sterogramiae), helongs to this tribe, and is one of the commonest of British beetles. It is of a stout form; less than an inch long; black, with metallic and blue reflexions on the undersurface. This species may often be heard droning through the air of a summer evening. We is almost impossible to ever-estimate the great-good per-formed by these insects. Not only do they hatten the removal from the ground of what becomes more offensive the longer it stays, but they carry the offensive matter to where plants grow, and, by distributing it in the soil, materially seniet their proper growth. Dusgator. (See Donion.)

DUNGEON. (See DONJON.)
DUNGERS, TUNEERS, GREMAN BAPTISTS, OF BRETSBEN, a religious sect of Baptists that originated in
Germany in the early past of the 18th century, about
twenty families of which left their native country, and settled in Pennsylvania, U.S., about 1719. They were speedily followed by others, and at length formed themselves into a distinct sect, and, in 1733, essablished a kind of monastic society at a place called Kphrata. The members adopted the dress of the White Friars, The members adopted the dress of the Winte Frans, and received monastic names, though they did not take any monastic vows. They hold the fundamental doctrines of Christianity, and acknowledge the Scriptures as the only infallible rule for faith and practice. They are chiefly remarkable for their rigid adherence to the precepts and ordinances of the New Testament, and do not admit of any innovations whatever on the established forms and ceremonies of Christ, even to the washing of the feet before recoving was continued. Their chief peculiarities are with regard to baptism and the sabbath. They hold to adult baptism, and administer the ordinauce by triple immersion; and they observe the seventh day as the sabbath. They washing of the feet before receiving the sacrament. they observe the seventh day as the sabbath. they observe the seventh day as the sabbath. They are exceedingly simple and peaceful in their manners, disclaiming viclence even in cases of self-defence, and suffering themselves to be defrauded and wronged rather than go to law. They consider future happiness only to be obtained by penance and outward mortification in this life, and deny the eternity of future punishment. This sect still exists in scattered bodies, wited in homosplane. chiefly in Pennsylvania.

DUNEOU PLIYOR, dun-see, a singular custom insti-tuted at Dunmow, in the county of Essex, in 1246, by Robert de Fitzwaiter. Its shjeet was the bestowal of a prise on a man and wife who had lived without quar-relling, on the following conditions:—"That whatever married couple will go to the priory, and, danseling on two hard pointed stones, will swear that they have not quarrelled nor repented of their marriage within a year and a day after its safetnation, shall smeare a fitch of bacon." The first prise was not assumed till two hundred years after the institution of the prise, and since that time there have only been subtle claim-ints for the fitch. The last two awards were made in 1855 and 1860. Mr. Harrison attenues the movelist, and others, have endeavoused of late years to per-petuate the custom. DUNNOW FLITCH, dun-mo', a singular custom insti-

### Duodecimo

example, suppose it were required to secertain the superficial contents of a piece of timber 12 feet 92 inches long and 3 feet 92 inches in width. In order to calculate this by the duodenimal scale, one dimension must be put under the other, the feet being piaced under the feet and the inches under the inches. The half-inch is expressed in lines, 6 lines going to the half-inch, 13 lines to a full inch :—

In this calculation, feet are considered as units of me sure, and inches are so many twelfths of unity. The units thus form the first place in the column, the twelfths the second, and the one hundred and forty-fourths the third. When the first line is multiplied fourths the third. When the first line is multiplied by 3 feets or 3 units, the result is 38 feet, \( \frac{1}{2} \) of a foot, and \( \frac{1}{16} \) of a foot. When the upper line is multiplied by \( \frac{1}{16} \) of a foot. When the upper line is multiplied by the six lines are made equal to \( \frac{1}{16} \). The first indeed to the other make \( \frac{1}{12} \) or \( \frac{1}{12} \) and \( \frac{1}{12} \). The dided to the other make \( \frac{1}{12} \) or \( \frac{1}{12} \) and \( \frac{1}{12} \). The ultimate result is as above, if a service forward. The ultimate result is as above, if a square feet and 120\( \frac{1}{2} \) square inches. To practical men the operation described is much simpler than the explanation, and beginners have great difficulty in meatering it. The dandecimal scale is not generally inserted in ordinary books of practical arithmetic. nary books of practical srithmetic.

DEODECINO, du-o-der-e-mo (Lat. duodecim, twelve), a term applied to a book when every sheet is folded six times, so as to make twelve leaves, or twenty-four pages. Is is usually abbreviated into 12mo.

DUODERUM, du-o-de'-num (Lat. duodesus, consisting

of twelve), in Anat., is the name given to the first por-tion of the small intestine, and was so called by the ancients because it was supposed not to exceed the breadth of twelve fingers; but as they dissected only animals, this does not hold true in the human subject. animals, this does not note true in the numan subject. It is from eight to nine inches in length, and commences at the pyloris end of the stomach. It first inclines upwards, backwards, and to the right, and, having arrived near the neck of the gall-bladder, it bends vertically downwards, and again changes to a transverse direction; thus forming two curves or angles. It is in this intestine that chylification of the food takes

It is in this intestime that chylification of the food takes place. (See Drouszion.)
Divelocation of the Cube, du-ple-kei'-shan (Lat. duplice, I double), a celebrated problem of ancient geometry, by which it was required to construct a cube whose solid contents should be double the contents of a given cube. The origin of this problem is as follows: During the occurrence of a plague at Athens, a deputation was sent to the oracle of Apolto at Delos, to learn what would stop or mitigate the catastrophe. The answer received was, that the plague would not cesse until they had doubled the size of the altar of the God. The shape of the altar was cubical, and the problem was, consequently, to find the side of another cube of twine the solid contents of the altar. This problem sould not be solved by plane geometry, as it cube of twice the solid contents of the altar. This problem sould not be solved by plane geometry, as it required the solution of a cubic equation. Hippocrates of Chica, however, by the insertion of two mean proportionals between two straight lines, resolved it into another and simpler problem. Several of the anoisnt geometers, including Archimedes, Eutocins, Esppus, and Misomades, discovered various methods of solving this problem by means of the higher curves. Newton and Huygens, among other celebrated modern mathematiciane, also gave much attention to the subject of the Duplication of the Cube.

DUBANERS, de-rol-mes (from Lat. derse, herd), in
Bot., the heart-wood or central portion of an exogenous stem. It is made up of wood-cells with thickened
sides, and which are impermeable to fluids, hard in
texture, coloured, and of a dry nature. (See ALBURNUE.)

# Durham University

DUBANTE, du-faile (Lat.), is a term completed in certain law phrases in the sense of during; as, duminal beas-placife, during pleasure; deresse vitt, during life. Durants minor state (during minority) if its ing-ilite. Jurants among another the minority of an infact executor, or the infant next of kin: durante attenties, an administration granted when the executor is out of the realing to continue in force until his returns. DURANS. deresse (Nor.), literally present hardship:

the realm, to continue in force until his retirra.

Durres, de-ress' (Nor.), literally means hardship; and hence, constraint of liberty. In Law, duress is of two kinds:—L. Duress of imprisonment, which is imprisonment or restraint of personal liberty; and 3. duress per minac (by mennaca or threats), cerviou imposed by fear of loss of life or limb. It is a general principle in law, that a contract made under compulsions not binding, and many acts will be excused on this ground which would otherwise be blameable; but the evil to be dreaded must be in some proportion to that which is commutated. A man some proportion to that which is commutated. some proportion to that which is committed. A man would not be excused for homicide to avoid even a considerable injury to himself. But in regard to civil transactions, a smaller degree of restraint will be a transactions, a smaller degree of restraint will be a sufficient ground for avoiding an obligation. Duress of imprisonment includes confinement of the person in any wise. The keeping of a man against his will in a private house, putting him in the street, is an imprisonment. If a man is under duress of imprisonment, and he seals a bond or the like, he may allege this duress and avoid the extorted bond. But if a man be lawfully imprisoned, and to procure his liberty, or on any other fair account, seals a bond or a deed, this is not duress of imprisonment, and he is not at liberty to avoid it. It is doubtful whether, in this country, mere duress of goods, as where the signature to an agreement dures of goods, as where the signature to an agreement was procured by a threat of detention of a person's goods or of injury to them, would suffice to avoid a contract; but in America this is held to be the case.

Contract; Dat: A America that is ent to be the case.

Duehan University, due-dm, dates its origin only,
from 1832, when a bill was introduced into parliament
to enable the dean and chapter of that see to appropriate an estate at South Shields for the establishment
and maintenance of a university for the advancement of
learning in connection with the said cathedral church. and maintenance of a university for the advancement of learning in connection with the said cathedral church, the late Bishop Van Middert engaging to provide even-tually for the warden, the professor of divinity, and the professor of Greek, by attaching prebendal stalls to the several offices. Under the authority of this act, the university was opened in 1833, and in 1835 a status was passed by the dean and chapter, and approved by the bidne intracting the ordinary management of the was passed by the dean and chapter, and approved by the bishop, intrusting the ordinary management of the university, under the bishop as visitor, and the dean and chapter as governors, to the warden, a senate, and a convocation. After a constitution and the studies had been satisfactorily arranged, a royal charter was had been satisfactorily arranged, a royal charter was granted under the great seal on the lat of June, 1837, incorporating the persons therein described by the name of "the warden, masters, and scholars of the university of Durham;" and granting them "all the rights and privileges which are assumed to the univer-sity by the act of parliament, or incident to a univer-sity established by royal charter." It consequently possesses the right of granting degrees. By an order-of her Majesty in council in 1841, it was provided that the office of warden should in future be permanently annexed to the desnery of Durham; a cassonry in the supered to the desnery of Durham; a caronry in the cathedral church was amound to each of the profesoathedral church was americal to each of the professor sorships of divinity and Greek; the professor of mathematics was appointed professor of mathematics and astronomy, with an increased sulary. It was also provided that a professorship of Hebrew and the other Oriental languages should be founded; and, in addition to the six fellowships which had been established by the dean and chapter, expiteen others were to be founded. Certain additional estates were assemed to the proving for this nurrough. A collect to be founded. Certain additional entaies were assigned to the university for this purpose. A college
was formed within the university, and building fitted
up for the reception of students, and censors and tutors appointed to watch over their conduct and direce
their studies. These accommodations were subsequently much enlarged, especially by the addition of
Durham Castle and its precinets. A new hall, called
"Histop Hatfield's Hall," was opened in 1986, said
unlarged by an additional building in 1989. Another
hall, called "Bishop Cosin's Hall," was opened in 1986.

711

## Durham University

In 1837 the benefits of the university were extended by the establishment of a course for students in vivil engineering and mining; and in 1852 additional facilities were given for students in medicine. Various alterations have since been made in the university, the last of which are by the ordinances of the university commissioners, but of the soft and administration of the university. In terms of these ordinances the bishop of Durham is to be the visitor of the university, and the dean of Durham the warden,—the latter exercising a general superintendence over the university, and convening the senate and convocation. The senate is to consist of the warden, professors, and tutors, and to manage the prodes, professors, and tutors, and to manage the pro-perty, maintain the discipline, direct the studies and examinations, and transact the business of the univeratty. The convocation is to consist of the wardens, professors, and tutors, and such persons as shall have proceeded to the second degree in the university; and will have power to confirm or reject what is submitted to it by the senate, but will have no power to originate or amend. The visitor has the appointment of the professors, to whose professorships canonics are annexed, and the senate will appoint all the other professors and all the store. There will be one professor of mathematics and astronomy; and in the school of physical science there will be at least three professors; namely, of chemistry and metallurgy, of geology and mineralogy, and of mining and machinery. To those professorahips not connected with canonics a fixed salary of £300 per annum will be annexed, and the tutors are each to have a salary of £250. Students will be of two kinds,—matriculated, whose names are placed on the register of the university, and non-matriculated,—such as have the permission of a professor to attend his lectures without his name being on the register. The matriculated student must reside elsewhere; and previous to matriculation he must state to what school he proposes to belong, and pass an elementary examinawill have power to confirm or reject what is submitted to it by the senate, but will have no power to originate proposes to belong, and pass an elementary examina-tion adapted to the studies of such school. The degrees are granted in three separate schools; viz.—1. Arts, classics, and mathematics; 2. theology; 3. physical science. No matriculated student is required to keep more than four terms in order to proceed to the degree of backelor in any of the three schools; and a graduate in any one of the three schools may, after an interval of three years, if he keep his name on the register of the university, proceed to the second degree in the same The matriculation fee will be £2, and the fee for tuition (each term) £5. Students resident in the college, or in any hall or house belonging to the university, must further make in advance the following pay-ments:—25 each term for rent, including furniture, and 21.5s. each week for battels, including service, and £1. 5s. each week for battels, including service, lighting, fuel, and all other domestic charges, except washing. A fee of 10s. is likewise payable each term to the university for keeping his name on the register. The fee for the first degree in any one of the times exhools is £2; for the second, £4. Forty open scholarships of £30 a year, each tenable for two years, are to be established, open to all persons, whether members of the university or not; but no member of the university shall be entitled to compete who shall have been a member lowest than one morth. These the university shall be entitled to compete who shall have been a member longer than one month. There are also to be forty scholarships of £50 a year each, open to all students commencing their second year, and tenable for one year; but, on the student graduing, in one school and becoming a student in some other, may be held for a second year. The scholarships are to be distributed between the three schools in proortion to the number of students at each respectively, portion to the number of students at each respectively, excepting that not more than one-third in number and value of them shall be held at any one time by the scholars in this school of physical science. There are also certain periests exholarshing, varying from £20 to £10. 10s. each, also tenable for two years, to be given to such persons as have most distinguished themselves in the examination for the university scholarships of £30 a year, and who are students in the school of arts. There are other private scholarships of from £25 to £10 s year each, given to such students of theology as have most distinguished themselves in the examination for the 200 scholarships.—Ref. Durkaw Univ. Oct.

## Dutch Liquid

DURIAM. (See DURIO.)
DURIO, du're-o (from Malay dury, thorny), in Bot., a gen. of plants belonging to the nat. ord. Steventiaces. The species D. sibethinus yields the fruit called the durian, which is highly esteemed in the southeastern parts of Asia, being accounted next in value to the delicious mangasteen. (See GAROIMIA.) It has, however, a strong smell, which renders it disagreeable at first to those unaccustomed to it; but the dislike to this smell is essensible soon overcome.

this smell is generally soon overcome, DURRA. (See HOLOUS.) DURIA. (See HOLOUS.)
DURIA ARMOSPHERIC, dust.—When a ray of any light enters a partially-darkened apartment through any amall aperture or chink in the shutters, or when a flood of intensely-brilliant light from the same source pours into a room through Venetian blinds or other means taken to exclude it to a certain extent, we can distinctly see small particles of various substances, familiarly called motes, floating about in the track of the sunbeam, and moving with creater or less randity the sunbeam, and moving with greater or less rapidity according to the extent to which the air is agitated in which they are suspended. Under ordinary dircumstances, these motes, or atmospheric dust, are invisible to human sight, being so minute that they can only be seen under the conditions that have been mentioned, through the reflection of strong sunlight from their surface, or by the sid of a powerful microscope. But whether they are visible to us or not, they are always present in the atmosphere that we breathe; and it is considered that the lower strats of the air immediately in contact with and above the surface of the earth are constantly impregnated with these small particles, of unappreciable weight and size, that are fragments of various organic and inorganic substances that have been worn away from the bodies of which they origibeen worn away from the bodies of which they originally formed a part, by friction and other causes. Scientific meteorologists ascribe the suspension of these small particles to the internal friction of the air, the resisting power of which increases very rapidly in proportion to the diminution of the particles themselves; that is to say, that, supposing we have two very small particles, one being the 1,000th part of an inch in dismeter and the other the 10,000th part of an inch, the power of the air to sustain the latter would be a hundred times greater than it would be to keep up the hundred times greater than it would be to keep up the former, although the diameter of the smaller particle former, although the diameter of the smaller particle has only been diminished to the tenth part of the greater one; so that it follows that when particles of dust are of extremely minute size, they would be held suspended almost in a state of perfect rest, provided that the air itself were free from agitation from any exciting cause. In many parts of the world, was toollections of this attacepheric dust are frequently formed, from excess that they not higher these explained. from causes that have not hitherto been explained; and to such an extent that they assume the appearance of thick have and banks of clouds, from which the terms "dust haze" and "dust storm" are frequently applied to them. When in Teneriffe, one of the Canary I for the purpose of making astronomical observations, Professor Smyth found these clouds of dust to be con-Professor Smyth found these clouds of dust to be constantly present in the atmosphere, often affecting the transmission of light to a great extent, so as to obscure the rising and setting of the sun, and to render the observation of the stars by day quite impossible, be sides gathering round the summit of the Peak of Tensriffe in horizontal strata, and almost concealing portions of it from view. This atmospheric haze, occasioned by particles of dust, has been noticed in South Africa and on the Himalays Mountains. Professor Smyth considers the convergence of the phanomanous to Africa and on the Himalays Mountains. Professor Smyth considers the occurrence of the phenomenon to be general throughout the world, although not so palpable to observation as in the districts already named; but he confesses his inability to determine where the dust came from, or whither it went, as well as why it should collect together in such quantities in mountainous regions. It has been discovered by Professor Ehrenberg, of Berlin, that the particles carried about by the wind, when submitted to chemical tests, consist of minute fragments of all kinds of mineral substances, mixed with mould and various organic bodies.—Ref. English Cyclopadis—Arie and Sciences.

DUTCH LIQUID, data his hard, in Chem. C.H.Cl., C. C.H.Cl. HO. When oleflant gas is mixed over water with chlorine in equal proportions, oily drope of a heavy, sweetish, aromatic liquid condeuse and

## Dutch Metal

sink in the water. This product is called Dutch liquid from the circumstance of its having been discovered in Holland, and its oily appearance gives the name to oledant gas. It is a very interesting substance to chemists, having been extensively employed by Faraday and Regnault in the elucidation of the theory of substitution.

DUTCH METAL, met. 41, in Metal., an alloy of copper and sine beaten into thin leaves resembling gold-leaf, from which it is readily distinguished by dissolving in

oil of vitriol

oil of vitriol.

Duren Rushes. (See Equiserum.)

Duren, du'-te (Ang.-Nor. from dee), is literally something due or owing by one person to another; hence, that which a person is bound by any natural, moral, or legal obligation to pay, do, or perform. In Pol. Ec., it is a tax or impost levied by the government or the public revenue. It is but reasonable that each individual who is member of a state should contribute in some area to the support of that state, and that to values who is member of a state should contribute in some way to the support of that state; and that, to some extent, in proportion to the benefits he derives from it. The apportioning the expenses of a government among the different classes of a community, in auch a way as not to affect the material prosperity of the state or of individuals, is one of the most difficult branches of the arts government. It is defined. the state or of individuals, is one of the most difficult branches of the art of government. High duties give rise to smuggling, and diminish the consumption of the article on which they are laid; while low duties increase the number of articles necessary to be taxed, and thus materially augment the expense of collection. The following general rules are laid down by Adam Smith on this subject:—1. That the subjects of every state aught to concribints to read the support of the state ought to contribute towards the support of the government as nearly as possible in proportion to their respective abilities; 2. that the tax which each individual is bound to pay ought to be certain, and not arbitrary; 3. that every tax ought to be levied at the time, or in the manner, in which it is most likely to be convenient for the contributor to pay it; and 4, that every tax ought to be so contrived as both to take out, and to keap ut of the receive of the receiver of the rec and to keep out, of the pockets of the people as little

and to keep out, of the potential of the people as fitting as possible over and above what it brings into the public treasury of the state. (See TAXATION.)

DWARF, dwaurf (Sax. dwerg, dweorg), in general language, a term applied to those human beings who are less in height than the average of their specific V. In a more restricted sense the word dwarf is applied to those cases in which there is a uniform applied to those cases in which there is a uniform arrest of growth. Among the ancients there was a general belief not only in the existence of dwarfs of great minuteness, but also in the existence of nations composed exclusively of them. In the works of Aristotle there is an account, which he declares he had from trustworthy sources, of a race of diminutive men and diminutive animals, living in the caves on the banks of the Nile. Their habits and customs, together with their recoverablest positions are also described. with their geographical positions, are also described by Pliny. The accounts of these pigmy people read very like Gulliver's accounts of the Lilliputians. Phi-letas, a poet, who was contemporary with Hippocrates, if all accounts are to be believed, was one of the smallest men that over lived. He was obliged to load himself with ballast in order that he might not be nimself with ballast in order that he might not be blown away by the wind. Nicephorus Calistus men-tions an Egyptian dwarf who "did not exceed a par-tridge in size" at the age of twenty-five. The most remarkable case of all, however, is that mentioned by Atheneus, of Aristatus, a poet, who was so small that he was invisible to the naked eye. Among the legends of the Scandinavians, the dwarfs occupy a conspicuous place. They are crafty, cunning elves, skilled in magic and in the working of metals. In Ethnology they are supposed to have been originally a race of oriental Lappe, who settled in Sweden and Norway after the Finns. In the mythology of the time they were looked upon as the connecting links between organic and inorganic nature. Giants were looked upon

## Dyeing

change ores into metals; and it was also believed that they took charge of the development of seeds and fruits. From these ideas probably arose the widely-apread and still existing belief in fairies and other diminutiva and still existing belief in fairtes and other diminutars beings, supposed to be favourably disposed towards certain members of the human race. These old tradi-tions, which belonged to western Europe, were broken through by the teaching and literature of the monks. All the strange legends and stories which had formerly been associated with dwarfs were transferred to the been associated with dwarfs were transferred to the saints. Nevertheless, among the rural population of all the nations in the west of Europe there is a strong belief in the existence of the diminuive beings whom Shakspere has so deliciously portrayed in "Midnummer Night's Dream." In Great Britain there are still a large number of persons who have a belief in the "faires" of England, the "brownies" of Scotland, and the "good people" of Ireland. Among the most remarkable dwarfs, properly so called, of modern times may be mentioned Sir Geoffrey Hudson, immortalized in Sir Walter Scott's "Peveril of the Peak." He was only eighteen inches in height at the age of thirty. After that age he rapidly grew to the height of three feet nine inches, and died at the age of thirty. He had and hands were enormous, but otherwise he was well proportioned. Another extraordinary dwarf was Court Joseph Borowiaski. At the age of them the set of the set of the was well proportioned, another in height, and at the age of thirty, three feet three inches. He was well proportioned, and married a woman of average size. He had several children of the ordinary size, and died at the extraordinary age, for a dwarf, of ninety-eight, in the county of Duram, in the west 1837. Wickless Extra commons. devil and his attendant spirits, and in some cases to for a dwarf, of ninety-eight, in the county of Dur-ham, in the year 1837. Nicholas Ferry, commonly known as Bebé, was another singular dwarf. His parents and relations were well-proportioned people: he himself war a seven months' child, and at his birth weighed less than a pound, and was not eight inches in length. He died at the age of twesty-three, not being more than three feet high. There is a wax model of him in the Museum of the Faculté de Médecine at Paris. At his death his bones were found to be com-pletely ossified; and from the disappearance of the cranial sutures, his skull fully resembled that of an aged man. In the present day, one of the most re-markable dwarfs is Charles Stratton, usually known as General Tom Thumb. He was exhibited in this comtry about twelve years ago. At that time his height was twenty-five inches, and his weight twenty-five pounds. It is a singular fact in relation to dwarfs, that although the growth and physical development arrested, in most cases the nervous system is fully developed.

DYRING, di'-ing (Sax. deagan, to dye), in Manuf.— Dyeing may be defined as the act of tinging or colouring absorbent materials by impregnating them with solu-tions of colouring matters. Colouring matters which effect this without the intervention of a third substance, or mordant, are called substantive colours, while those or morast, are cancularious account which require such aid are called adjective. The exact way in which dye stuffs act upon fibrous materials has not yet been investigated as fully as it deserves; the generally received opinion is that the fibre has an affinity generally received opinion is that the fibre has an affinity for the colouring matter in the case of substantive dyes, and for the mordant, which in its turn has an affinity for the colouring matter of adjective dyes. Another opinion is, that the fibres contain pores which absorb the dye, forming an insoluble lake in the case of mor, danted dyes. However this may be, it is certain that different materials take dyes in different proportions. Thus silk and wool take the coal-tar dyes in the most perfect manner, but cotton requires the intervention of a powerful unieral or animal mordant. The operations that take place in dveing are, mordanting, ageor a powerful unineral or animal mordant. The opera-tions that take place in dveing are, mordanting, age-ing, dunging, dyeing, and clearing. The principal mordants used are alumina, extensively employed for woollens and silks in the form of alum and cream of textar, peroxide of iron, which is much used in the form of protacetate for logwood and madder. Fer-oxide of tin and several other metallic oxides are used for the same nurnose. also albumen, caseline, and other ganic and inorganic nature. Giants were looked upon as the embodiment of the grander and more conspicuous forces of nature (see Giarts), while dwarfs represented the subcrdinate, but still incomprehensible, from the belief that dwarfs were more inclined to assist ordinary-mortals than to further the ends of the giants, they began to be looked upon as animal subctances in different forms. After the fabric beings well disposed towards man: they were supposed to sppear at strange moments, instructing him how to through which a current of stam and air is passing, by

713

2 4 3

means of which the union between the fibre and the mordant is guidened very considerably. The cloth is then dunged, in order to remove the impedituous mordant not absorbed by the fibre. This was formerly effected by passing the fibric fibrough a mixture of cow-dung and water; but this filthy operation has been superseded in a great measure by the introduction of what are turned dang substitutes. The principal dung substitutes in use at present are the arsenite, are interested in the at present are the amendation of acquaints oots. The action of these is chemical; whereas that of the cowodung was supposed to be merely mechanical, by supplying the unabsorbed mordant with a librous material in a firm state of division. Dunging is one of the most important processes in the dyeing proper, which is effected by runging of the fibric through the solution of the dyestuff, the colour being modified, more or less, by the nature of the mordant used. It would be impossible in a short space to give an account of the different methods adopted affected colours; but a description of the means used to produce the more common colours will be interesting to the reader. Hiscks are generally produced by logwood or salls with an iron mordant. means of which the union between the fibre and the mordant is guickened very considerably. The cloth is means used to protuse the more common colours will be interesting to the reader. Blacks are generally produced by logwood or galls, with an iron mordant. Common black silks are dyed with logwood and fustic, fron being seed as a mordant. The best silks are dyed black on a blue ground. Woollen goods are first dyed black on a blue ground. Woollen goods are first dyed blue with indigo, and afterwards with sumac, logwood, and green copperss or sulphate of copper. Cotton and linen goods are dyed black in a very similar manner. Chromate of notash is also sometimes used with log-Obsomate of potash is also sometimes used with logwood; but practical dyers say that it possesses no great wood; but practical dyers say that it possesses no great advantages over blue or green copperas. Blues are produced from indigo, either in the form of sulphate or in aqueous solution. Pruesian blue, with a persait of iron or tin as a mordant, gives a very splendid dark blue; and, of late, several blues of novel shades have been produced from coal-tar. Reds are obtained by using cochineal, safflower, lac-dye, madder, or log-wood, with a tin mordant. Fine orimaon parples are obtained from coal-tar, and are known under the wood, with a tin mordant. Fine orinson purples are obtained from coal-tar, and are known under the popular name of magenta. The most important yellow dyes are queretirou, fustic, turmeric, arnotto, and French or Fersian berries. By cembining these different colours, and by adapting the mordants, colours of every concelvable shade and hue are casily obtained. When the fabric has received the colour intended, it is washed in a solution of soap to which a little alkali has been added, after which it is holled in water with as washed in a solution of soap to which a little sixal shas been added, after which it is boiled in water with or without the addition of solution of tin or other brightening substance. It is then said to be fast, which means that it will not be washed out. The chemistry of dysing has of late years attracted the attention of our greatest chemists, and has reached such perfection that a loose colour is almost unknown. The matter has received the most minute investigation at the hands has received the most minute investigation at the hands of such men as Hofmann, Stenhouse, Schunck, Rochleder, Persoz, and a host of others, who have not only benefited the art of dycing by their researches, but have also discovered new facts leading to new theories of chemical philosophy. The last great discovery made in this direction is that of the coal-tar dyes, a discovery that will eventually make us the dye-producing matter of Europe. nation of Eurepe.

DIR-STUPPS. (See Colouring Matters.) BYING DECLARATION. (See DECLARATION, DYING,

and Evipence.)
Dink, dike (Du. dyk), an embankment of earth, sometimes revetted with missonry, or secured with a sleping front of stonework to prevent the water of the ocean or any river from overflowing the low lands that have been drained and brought into cultivation. that have been drained and brought into cultivation. The most remarkable works of this kind are in Holland, some of which have been thrown up along the banks of the Rhice; as well as other parts of the country, for the protection of the pasture-lands. These dyles are very broad at the base, and slope gradually towards the top, along which reads, and sometimes sanals, are constructed, that serve to curry off the vater from the meadows, which is lifted to the level of the canal by pumping. The dyles along the Heider is six miles in length. The French call these structures levels, and the lowlands on either side of the Mississippi, near New Orleans, are protected from inundation by those embankments. The communication of dykes is an important part of the scheme for effecting the drainage of any tract of marsh land.

Or any tract or meran and.

DEER, in Gool, a term applied to any wall-like mass
of igneous rock filling up a fissure in other rocks. A
dyke may come up through any kind of previouslyexisting rock, whether igneous or aqueous. When the
matter of the dyke is harder than the intersected strata, snattee to one questionance tune me inversed arrea-and these have been subjected to waste and denuis-tion, the igneous wall-like mass may be traced for mile across a country; and on the other hand, where the rock-matter of the dyler has been softer, its course may also be traced by marrow wall-sided discurse and linear dividuality decreasions. A member of a second and may also be traced by narrow wall-aded assures seal linear ditch-like depressions. A wonderful example of a trap-dyke is the one so well known in the north of England as the Cockield Fell dyke, a nearly vertical wall of trap 18 or 20 yards thick, which runs in nearly a straight line from north-west to south-west for a distance of these traces of these traces of the straight line from north-west to south-west for a distance of the straight line from the straight line s a straight line from north-west to south-west for a dis-tance of about seventy miles, enthing through all be rocks from the coal-measures into the lower colites, Its igneous origin is proved by the baked appearance of the rocks in its neighbourhood. This coal in sp-proaching the dyke begins to be affested at a distance of fifty yards; it first loses the calcareous spar which lines its joints and faces, and begins to look drill, grows teader and abort, and also loses its quality for burn-ing. As it comes nearer it segment the appearance of ing. As it comes nearer it assumes the appearance of a half-burnt einder, and approaching still mearer it becomes converted into a real cinder. Immediately in contact with the dyke it forms a black substance, re-

sembling compressed soot. The seem of coal is ori-ginally from air to eight feet thick; but in approach-ing the dyke it gets thinner and thinner, being ulti-mately reduced to nine inches.—Ref. Jukes's Manual of Geology.

DYNAMICS, di-num'-iks (Gr. dunumis, power), that division of mathematics which treats of force, considered as producing motion in bodies. Force may be defined as any cause which changes, or tends to change, a body's state of rest or motion. The case of force a body's state of rest or motion. The case of force tending to move bodies from rost will be found under the subject of STATICS. The case of force actually producing motion, or changing motion, belongs to Dy-namics. Some of the most distinguished philosophers have given much time and labour to the investigation of this branch of mathematics. Among these may be mentioned Newton, Huygens, Euler, D'Alembert, Poinsot, and others. The dootrine of dynamics is divided into several distinct heads. First, the names and definitions of the various terms employed; such as force, velocity, accumulating velocity, moving relocity, motion, accumulating motion, &c. The second branch of dynamics treats of the movement of points, and is divided into two classes of problems,—direct and inverse. In the first case the path of a point is determined when In the first case the path of a point is determined when the forces acting upon it are given; and in the second case the force or forces acting upon a point are deter-mined when the path of the point is given. In the third brauch of dynamics the motion of a rigid sys-tem of points or a solid body is treated of. D'Alembert first haid down the general method for treating problems in rigid dynamics. Motions of rotation are treated of in the fourth branch of dynamics. The three laws of motion upon which most of the problems in dynamics depend are as follows: First, a body under the action of no external force will remain at rest, or move uniformly in a straight line. Second, when any num-ber of forces act upon a body in motion, each produces its whole effect in altering the magnitude and direction

its whole effect in sitering the magnitude and direction of the body's velocity, as if it acted singly on the body at rest. Third, when pressure produces motion in a body, the momentum generated in a unit of time, supposing the pressure constant, or which would be generated supposing the pressure variable, is proportional to the pressure. (See CENTRAL FORCES, FORCE, PERCUSSION, PROGRETILES.)

DYSAKOMETER, di-númom'e-ter (Gr. dienamic, power, and metrosis, to measure), the name given to all instruments that are constructed for the purpose of measuring the power that can be exerted by the human frame, animals, or machifery, whether by a single effort of strength or by a continuous series of efforts exercised during any given time. In estimating the amount of work performed by any motive power by

#### Dysentery

means of a machine contrived for the purpose, we have to consider the force that has been applied and the space through which this force has been exerted. If a horse pull a fundaedweight along a mile of level ground in half as hour, or half a horderdweight over two miles in the same tune, he will have performed the same smouth of work in both cases; but if he continue to perform the same take for an hour in either case, it is manifest that he will have done double the quantity. We see, then, that the amount of work done must be estimated by the force applied to accomplish it and the space of time for which the application of the force is kept up; in other words, it will be measured by the force exerted multiplied by the space of time through which it continues to set. To ascertain this with accuracy, dynamometers are required. The simplest kinds of these instruments are those used to determine the force which any man or animal can exert by a single effort. They vary considerably is form, as the force happens to be applied to the machine by tension or pressure, or by strking it with the elsewhed first to determine the weight of the blow that a person can deliver. The amount of power exerted is indicated by a needle moving along an horizontal or circular scale. a needle moving along an horizontal or circular scale The best, perhaps, for ascertaining the strength of the human body, or that of an animal, is the dynamometer invented by Regnier, which consists of an elliptic spring of steel fitted with a hook at one end and handles and a graduated index at the other, with appliances to more the index needle to the proper extent when any force is applied to the machine. To test the strength of the body, the machine is fastened to the ground by the book at the lower end, which is inserted in a socket imbedded in a strong beam. The person festing his power than plants his feet firmly against the beam, and, grasping the handles at the other and, pulls them with the utmost strength he can exert. This causes which the unions strength he can call the the sides of the spring to be brought more closely together than before, and the result of the force exerted to accomplish this is registered on the index. The strength of the arms is tested by squeszing the sides of the springs together by pressing on them with both hands. To measure the power of animals, the machine is fastened to a stont post or tree, and the animal is attached by a bar and traces to the handles or a ring passed through them. It is, however, manifest that the value of a continuous force cannot be measured by such machines as these, unless it were uniform. This, however, is far from being the case, as the force ex-erted by animals, and machines as well, is continually varying; but the work done during a long space of time can be accurately measured by machines contrived for the purpose; among which Morin's dynamometer seems to deserve especial notice. This contrivance measures the work done by machines by the bending of a spring, which is acted on by the motive power, and managed so as to register the influence that this exerts upon it by the action of pencils that describe lines on a strip of paper, from which the amount of work effected can easily be calculated. The construction, however, of this machine, and all of a similar nature, is too compli-cated to be thoroughly comprehended without a long cause to be thoroughly comprehended without a long and minute description, accompanied by elaborate diagrams. Ample information on the subject will be found in the English Cyclopedia—Arts and Sciences; Nichol's Cyclopedia, of the Physical Sciences; Tomlinson's Cyclopedia of United Arts; and Ganot's Physics. DYMENTERY, distension of Cyclopedia of United Sciences, Tom diag.

with difficulty, and esteron, intestine), is a disease characterized by frequent mucous or bloody stools, attended with griping pains in the abdomen, straining, and tensames. It differs from distribus in that while in the latter the stools are facel, in this there is a retention of the natural faces, or they are expelled from time to time in amail hard separate lumps, termed suplate. Dyseatery consists essentially in inflamma-tion of the mucous mesobrane of the large intestines, and, in the acute form or stage of the disease, is atand, in the soute form or stage of the disease, is at-tended with fever. Dysestery is one of the peats of hot climates, and in all tropical countries, at certain seasons of the year, it is very prevalent and destructive. It is, however, among fleets and armise that this maindy most displays its deadly power; so that it has been termed the "spourge of armies and the most fatal of all their diseases." At one time it was very prevalent 715

## Dyspensie

in this country; but now it is not a very commo a very serious disorder here. The forms of this it and the circumstances under which it prevails are and the diretting and many speculations have been formed regarding it. It is now a primary, now a connectaine and now a symptomatic disease. It has been ascribed to exposure to wet and cold, to the use of numbries some food, to the agency of malaria, to contaging the most violent forms of this disease occur. in warm climates and in situations where the body is exposed to extreme alternations of heat and cold; a hence there is every reason to believe that these influcacce are largely concerned in its production. Its food or malarious poison would induce it as a primary disease; and the general opinion among medical men is that it is not contagious. Generally one of the earliest symptoms of dysentery is an uneasiness of the abdomen, soon amounting to pain of a griping cha-racter, particularly in the umbilical region, attended with an inclination to go to stool, and temporarily relieved by evacuation. As the disease becomes dewith an inclination to go to stool, and temporarily relieved by evacuation. As the disease becomes developed, the relief is but transient; the desires to go to stool is more frequent and importunate; the discharge is scanty, and what is voided is either alterative and the stool of the stool to come away, the expulsion of which would cure him, and is irresistibly impelled to strain violently to get rid of the irritation. In an advanced state the stools become greenish or black, and very footid; the bladder frequently sympathizes with the rectum, and nauses and vomiting sometimes eneue. The patient passes sleepless or dreamy and disturbed nights, and is lowspirited and desponding. In "stal ones the pulse becomes very small and rapid, the features sharpen, the surface grows cold, and death at length sets in. The duration of this disease is very various. In some cases it may prove fatal in a few days, or even hours; in others it may last for weeks or months. Two stages are recognized of this disease, —the inflammatory and that of ulceration. In the inflaminflammatory and that of ulceration. In the inflammatory form, when the fever is high and the pain intense, blood letting from the arm is generally recommended, and also the local abstraction of the blood by leeches or enpping. Dover's powder is also given as a sadorific, and prefuse sweating encouraged. Purgatives are to be employed with great caution. If the colon be distended with feculant matter which it cannot discharge, then the midded purgatives, such as castor oil, should be administered, and cantiously repeated until the whole of the irritating matter is removed. If on the contrary, there is no and cantiously repeated into the whole of the irritating matter is removed. If, on the contrary, there is no accumulation of feculent matter, the use of purgatives is to be avoided. After the inflammatory state has been reduced by blood-letting, and the accumulated fesces ejected by purgatives, the great object is to stothe the irritated membrane by opiates, and to strengthen the system by gentle tonics and a light nourishing diet. If the disease is not cut short by this reached the second stars and hecome method, but has reached the second stage and become chrouic, the most effectual remedies appear to be laxsurroute, the most executal remedies appear to be lax-sitives and opistes given alternately, and combined with such medicines as promote perspiration. The abdomen should be awathed in fiannel, and much benefit may be obtained from the employment of clysters, if there be not too much tensamus to admit of the introduction of the pipe. The food should be farinaceous and simple, and great care must be taken during conva-leasence to increme to return to improper diet, and any

simple, and great care must be taken during conva-leasence to prevent a return to improper diet, and any fresh exposure to cold.—Ref. Watson's Lectures on the Principles and Practice of Physic.
DESPENSIA, dis-pay-sed (Gr. duspepsia, from dus, had, and segle. I concort or digest), in Pathol, in a bad or difficult digestion. It is by means of dipestion that the food which is taken into the stomach is com-verted into nutritive matter for supplying the waste-that is constantly sping on in the system; hence anyvaried into nutritive matter for supplying the waste-that is constantly going on in the system; hence engi-thing that interferes with the due supply of nutritive matter materially affects the system, and may intro-duce a long series of ills. The complicated series of

operations by which digestion is carried on renders indigestion one of the most prevalent of the ills to which human flesh is subject,—it is the prevailing malady of civilized life. "We are, "say Dr. Watson, "more often consulted about the disorders that belong to eating and drinking than, perhaps, about any others; and I know of no medical topic concerning which there is aflost, both within and beyond the profession, so much ignorant dogmatism and quackery. Referring to that article for an account of the various operation that are carried on in digestion, and a derangement of any of which would produce indigestion, we shall here chiefly confine our attention to that which is the most chiefly confine our attention to that which is the most frequent cause of this disorder,—a faulty performance of the functions of the stomach. It is here, as is well known, that the principal change is effected in the food. Whonever food is taken into the stomach, there is in the natural state a secretion of gastric juice, which acts chemically upon it, and by which it is disolved or converted into chyme. While this process going on, it is facilitated by a sort of churning or evolving movement of the stomach, and at length it passes by degrees through the pyloric extremity of the stomach into the intestines. Dyspopsia, therefore, may be occasioned by a deficient supply of gastric juice, so that the food is not properly dissolved, or from a too torpid or too irritable condition of the muscular fibres of the stomach, in consequence of which the chyme is detained too long, or ejected soo muscular fibres of the stomach, in consequence of which the chyme is detained too long, or ejected too soon. A weak dyspeptic stomach acts very slowly, or not at all, on many kinds of food. They undergo spontaneous changes, promoted by the mere warmth and moisture of the stomach; gases are extricated, acids are formed, and, perhaps, the half-digested mass is at length expelled by vomiting, or it passes undissolved into the duodenum, and becomes a source of irritation and disturbance during the whole of its passage through the intestines. One of the most frequent signs of indigestion is a loss of appetite, no desire for food, or, perhaps, even an absolute repugnance and disgust at the very thought of eating. Sometimes the appetite is capricious and uncertain, or may times the appetite is capricious and uncertain, or may even be morbidly craving and ravenous. Sometimes nauses comes on immediately after the food is swallowed; and sometimes without any nauses, but after the lapse of some time, the food is ejected by vomiting. There is, also, usually an obscure feeling of uneasiness fulness, distension, and weight in the region of the stomach, occasionally amounting to pain, or even se-vere pain, with flatulence and eructation. Some per-sons suffer pain when the stomach is empty, others immediately after taking food, or the pain may not begin for two or three hours after a meal, and then continue for some hours. Sometimes the pain comes on at uncertain intervals in the most violent paroxysms, accompanied by a sensation of distension, much anxiety, and extreme restlessness. Costiveness is a very frequent concomitant of dyspepsia, but sometimes it is attended with diarrhosa. Among the innumerable dis-orders in more distant parts that are produced by orders in more distant parts that are produced by dyspepsis are palpitations of the heart, irregularities of the pulse, asthma, pain in the head, with the loss of mental energy, and some confusion of thought. One of the worst of the occasional concomitants of dyspepsis is that state of mind which is known as hypochondriasis. There is languor, listlessness, or want of resolution, with an apprehension of some great evil in the future. Such persons are particularly attentive to the state of their own health, and, from any unusual feeling, perhaps of the slightest kind, they apprehend great danger, or even death itself. Of the causes that induce dyspepsis, are indigestion, noxious or irritating substances taker into the stomach as food or drink, -such as tainted meat, decayed vegetables, unripe fruit, very soid matters, alcoholic liquors, &c.; and even wholesome food taken too frequently, or in too large a quantity, especially when its nature is very nutritious or in a very being highly seasoned. The abuse of fermented and spirituous liquors is one of the most frequent causes of dyspepsis; and the consumption of large quantities of

716

close application to business, strong mental smotion, or exposure to a cold or moist stmosphere. In the treatment of dyspepsia it is to be borne in mind that it is not so much medicines that will semove the present discomfort that are required, as a discontinuance of those habits which have generated the discomfort. Hence one great and indispensable principle in the treatment of dyspepsia is that of restricting the quantity of food taken at any one time. The amount of the food introduced into the stomach should be kept within the limits of its capacities and powers. Another very important principle is, that the stomach should have time to perform one task before another is imposed upon it. Mr. Abernethy always advised his patients to interpose at least six hours between one meal and another. From three to five hours ought to be allowed for the digestion of a meal, and one hour more for the stomach to rest in. As different sriciles of food are soluble in the stomach with various degrees of readiness, it is of importance to select those articles that are soluble with least difficulty, as well as to avoid mixing together in the stomach various substances which are of different degrees of solubility; hence it is salutary to dine off one dish. Animal food is much easier of digestion in the human stomach than vegetable, and a much less quantity of it is needed for nutriment, while it is not so likely to generate acidity. This, with a moderate portion of thoroughly-cooked vegetables, is, perhaps, the dict best suited for a feeble stomach. As regards the use of spirituous or fermented liquors, in the opinion of Dr. Watson—though some allowance must, no doubt, be made for custom—most dyspeptic persons would be better without any of these drinks. Finally, change of air, change of secne, change of society, usually exert a very beneficial effect in this disorder. "Get the patient of review in search of health, and the chances are in favour of his finding it."—Ref. Lectures on the Prixociples and Practice of Physic, by Dr.

pace, I breathe), in Path, is an embarrassed or laborious breathing. It is owing to a disturbance of she natural and healthy relation that ought to subsist between the quantities of blood and air in the lungs. When the quantity of atmospheric air that reaches the lungs is by any means diminished, or when there is more venous blood sent to the lungs than can be arternized under the ordinary modes of inspiration, then instinctive efforts are made to increase the quantity of air by increasing the number of acts of inspiration. Hence dyspiness may arise from a number of causes; as croup or laryngitis, diminishing the only inlet for the air; pressure upon the lung, or any other means by which its size is diminished, or it is rendered less spongy; or by increased action of the heart. The hysician has thus to decide, in such a case, whether the heart or the lungs he at fault, or both, or neither, and to prescribe accordingly.

E

mental energy, and some confusion of thought. One of the worst of the excessional concomitants of dyspepsis is that state of mind which is known as hypochondrissis in Englage, and it has a greater variety of sounds that state of mind which is known as hypochondrissis in Englage, and it has a greater variety of sounds in Englase, and it has a greater variety of sounds in Englase, and it has a greater variety of sounds in Englase, and it has a greater variety of sounds in Englase, and it has a greater variety of sounds in Englase, and it has a greater variety of sounds in Englase, and it has a greater variety of sounds in Englase, and it has a greater variety of sounds in Englase, and it has a greater variety of sounds in Englase, and the superhead by There is language, and it has a greater variety of sounds in any other tonge. Raqua, \*-gi (Fr. aigle, Lat. aguila), a gen. of birds of prey, constituting the largest of the Falconida. In these birds the bill is of moderate length, with the ridge of the upper mandible straight from the base, at least as far as the end of the cere, beyond which it is destitute of the strongly hooked and acute, but is destitute of the strongly hooked and acute, but destitute of the strong tooth characteristic of the true falcons; and the lateral margins are more or less festioned. The wings are long and usually pointed, with the third, fourth, and tifth quills longest; and the tail is long, broad, and rounded. The tars are rather long, but vary greatly in their clothing, being sometimes is long, broad, and rounded. The tarsi are rather long, but vary greatly in their clothing, being sometimes covered with scales of various forms, and sometimes completely clothed with feathers. The toes are long and powerful, the inner one being usually stronger than the outer: they are all armed with long, strong, and greatly acute claws. The finest of the British species, and perhaps the finest of the group, is the well-known golden cagle (Aquila chrysadios). It is a solitary bird, building its nest on ledges of rook in the wildest part of the country, and far from the habitations of man. It is very common in Sweden, in Scotland, in the Trol. Francouns, and Susbia; more rare in in the Tyrol, Franconia, and Suabia; more rare in Italy and Switzerland; rather common in France, in the mountains of Auvergne, and in the Pyrenees; rare the mountains of Auvergne, and in the Pyrenees; rare in Holland; and less common in the Oriental countries. The general colour of the plumage is deep brown, mixed with tawny on the head and neck, the feathers on the back being finely shaded with a darker hue. The wings, when closed, reach to the end of the tail; the quilfeathers are checolate-coloured, with white shafts; the tail brown; feet yellow. It measures in length about three feet, with an expansion of wing of at least seven feet, and weighe about fourteen pounds. Its strength is prodigious. It has been seen to carry up to its lofty nest lambs of several weeks old, and even young fawns. It, however, now and then comes to harm through atures very much smaller than those mentioned. Bishop Stanley relates that a gamekeeper out on the moors observed an eagle rise from the ground with something it had seized as its prey. For a time it sailed away steadily, but suddenly it became agitated, and, after fluttering irregularly for a short time, spired upwards in a straight line to a vast height, and then, ceasing to flap its wings, fell headlong to the ground. Struck with so unaccountable an occurrence, the eagle fell suddenly and unaccountably from a great cagle fell suddenly and unaccountably from a great height, and, on being approached, a weasel peered out from under the great bird's wing, and scuttled off. The ring-tailed eagle is the one and two-year-old young of the golden eagle. Besides the golden eagle, there is snother British species of this family, which feeds on fish, and, for this reason, is always met in the neigh-bourhood of water. This is the white-tailed see-eagle (Hallockus albicilla). It is rather larger than the solden asade, but exhibits a smaller strant of wing golden eagle, but exhibits a smaller extent of wing. Despite this bird's large size and strength, it rarely Despite this bird's large size and strength, it rarely ventures to attack any animal larger than a hare; indeed, it seems to prefer its prey ready killed, and subsists for the greater part on stranded fish and the carrion carcases of such animals as it may find. This bird builds upon ledges of rocks that overhang the sea: the nest is composed of sticks, seaweed, and similar coarse material. The American or white-headed seamed. \*\*Italiatus Laucasenhalus\*\*) is found in every part. the nest is composed of sticks, seewhile-headed seacourse material. The American or white-headed seagle (Halladists leacoesphalex) is found in every part of the United States of America, preferring the low lands near the sea-shore to mountainous districts. It is this bird that America takes as its eymbol. It is about the size of the golden eagle, but of a lighter colour, and the legs are cayly feathered a little way below the knees. The bill is large, acutely hooked, and of a bluish colour. A row of strong bristly reatherer hangs from its lower mandible, and from this it takes its consistent name of Bearded eagle.

Its chief prey is fish, and he commonly secures it as it swims near the surface of the water. It would seem, however, to derive not a little of its aliment seem, however, to derive not a listle of its aliment by a stratagem much more ingenious than honest. The osprey, or hawk-flah, generally abides in the white-headed eagle's neighbourhood, and occasionally the latter, instead of fishing for himself, larks near the osprey. This bird, sailing gently over the water, watches till a fish appears in sight, and then, to use Wilson's words, "like a perpendicular torrent, it plunges into the sea with a loud, rushing sound and with the certainty of a rifle. At this moment, the eager looks of the eagle are all ardour, and, levelling his neck for flight, he sees the fish-hawk once more emerging, struggling with its prey, and mounting more emerging, struggling with its prey, and mounting in the air with screams of exultation. These are a signal for our hero, who, launching into the air, instantly gives chase; soon gains on the fish-hawk; each exerts his utmost to mount above the other. each exerts his utmost to mount above the other. The unencumbered eagle rapidly advances, and is just on the point of reaching his opponent, when, with a sudden scream, the latter drops his fish; the eagle, poising himself for a moment, as if to take more certain aim, descends like a whirlwind, snatches it in his grasp before it reaches the water, and bears it silently away to the woods." Besides those enumerated, there are the growned acids (forth, opposed) found in

grasp before it reaches the water, and bears it signify away to the woods." Besides those enumerated, there are the crowned eagle (Aguila, coronala) found in Africa; the superb eagle (Falco superbus) of Guinea; the cheels eagle (Falco Cheela) of India; the royal eagle (Aguila imperiatio) of South America; the royal eagle (Aguila imperiatio) of South America; the royal eagle (Aguila vilturina) of Caffraris.

EAGLE, in Her., the emblem of dominion, as well as of courage and magnanimity. It is generally borne with extended wings and lege, or "displayed," as it is technically termed. The eagle is assumed by Russia, Frussia, Austria, Poland, and America, as their national emblem, as the lion is the emblem of Great Britain. The eagle of Austria is represented with two heads. It was used by the Romans, Persiana, and Egyptians as a symbol or badge of empire.

EAGLE, in Mil.—The standards of the legions of the Romans were generally surmounted by the figure of an eagle perched on a small cross-bar at the top of the staff of the banner, with its wings raised. It was about the size of a pigeon or sparrow-hawk, and expecting covered throadsable in its claws. This

about the size of a pigeon or sparrow-hawk, and sometimes carried thunderbolts in its claws. This custom has been adopted in the French army, and all the French military flags are surmounted with a small

the French military flags are surmounted with a small eagle made of the new metal aluminium, and gilt.

Eagle, a gold coin of the value of ten dollars, current in the States of North America. (See Dollar,)

Eagle, Onder of the Black, an order of knights in Prussis, founded by the elector of Brandenburg on the day of his coronation as king of Prussis, Jan. 17, 1701. In addition to the princes of the royal family, the number of the knights was originally thirty, but it is now unlimited. A chapter is held twice in the year, and the anadidates for normalization must bathirty was a now unlimited. A chapter is held twice in the year, and the candidates for nomination must be thirty years of age, and able to prove their noble descent through four generations by both parents. The Black Eagle is the highest order of knighthood in Prussia, and, with the exception of foreign princes and knights of the order of St. John, no member of it is allowed to wear any other order along with it. It is generally worn by those who are in attendance upon the king; consequently makes the bolds it is reconstituted to travel those who are in attendance upon the king; consequently, no one who holds it is permitted to travel more than twenty German miles from the court without giving due notice. Knights of the Black Eagle are also knights of the Red Eagle. The insignia belouging to the order of the Black Eagle consist of an octagonal cross of blue enamel, with a black eagle between each of the arms of the cross. The cross is suspended across the left shoulder by a broad orange-coloured ribbon. On the left breast an embroidered silver star is worn. In the centre of the star is displayed a black tying eagle, bearing a thunderbolt in one claw and a is worn. In the centre of the star is displayed a black flying eagle, bearing a thunderbolt in one claw and a larrel wreath in the other. The legend round the eagle is "Suum quique." Every new member of the order pays fifty ducats towards the support of the order pays fifty ducats towards the support of the orders as a support of the order and the support of the order. Eagle, Orderson the roder and results for the order of knights in Prussia, founded by the margraf George Frederick Charles, in 1734, as a reorganization of the order de

Is Simplified instituted by the hereditary prince is Simulated by the hereditary primes of Anapach and Baireuth early in the centity. Fasterisk Milliam II. raised the order of the Beddingle. 1791 to the reak of the stoned crier in the measurements. The decoration consisted of a state Malasse cross, surmounted by a royal crown, with the Brandenburg cagle in the corner. In 1810 at man reorganized, two additional cinsees being included in it. The second of these classes was, in 1830, subdivided into two, only one of which wors the cross.

EAGLE-HAWK (Morpheus, or Spiendles), a gen. of Fallowids of the Hagie group, but consisting of species of comparatively small size, and characterized by short wings, long alender legs (tarsi), and comparatively fashle soes and claws. They are natived warm alimates, chiefly of South America, but also of Africa and the Best Indies.

Racus, Cow (Bub), a gen. of the Owl fam., found in

RAGIR-OWL (Bubo), a gen. of the Owl fam., found in

EAGLE-STORM, in Min., a variety of argillaceous iron ore, having a concentric structure and occasionally

ore, having a concentric structure and occasionally so decomposed as to contain a loose kernel that rattiles when shaken. The ancients imagined that this stone was the egg of the engle, the internal nedule being the embryo englet. (See also Graopa.)

Han, ser (Ang.-Sax.), in Anat. and Physiol., is the organ of hearing, and consists of three parts,—the external ear, the middle ear or tympanum, and the internal ear, or labyrinth. The external ear consists of an expanded trumpet-shaped cartilaginous structure, called the pinna or anticle, which collects the sounds, and a tube which conveys these sounds to the meanument, and fixed to the mangin of the meature sanditorius externus. It is of as owal form, with the margin olded and the larger and placed upwards. The round rimilite margin is called the laster, the depression immediately within which being the groove or fosse of the diately within which being the groove or focus of the helix. Within the latter is allarge elevation, called the heliz. Within the latter is alarge elevation, called the antiheliz, which presents at the upper part a well-marked depression,—the fossa of the antiheliz. In the centre of the pinns is a deep hellow, named the concise, which conducts to the opening of the meature anditorine. In front of that hellow is a projection of a triangular shape, called the tragus; and on the opposite side of the bollow, rather below the level of the tragus, is another projection,—the antitragus. Inferiorly the pinns is terminated by anoft pendulous part, called the lobule. The auditory canal, meature anditories externas, or the table by which sound is conversed from the pinns to the internal ear or tempanum, veyed from the pinns to the internal ear or tempenum is about an inch and a quarter in length, and is formed partly by bone and partly by certilage and membrane. Its direction is obliquely forwards and invards, and is somewhat bent downwards towards the middle, so that it is rather higher there than at either extremity. In shape it is rather fishtened from before, backwards, and it is necrowest at the bent part. The cartilaginous portion is about half an inch in length, and is formed and it is searchest at the best part. The carriagenous portion is about half as nosh in length, and is formed by the cartilage of the concha and tragus being projected inwards to the circumference of the auditory passage, to which it is firmly attached. At the upper and back part of the tube the cartilage is deficient, and its place is supplied by fibron membrane. The cosecous portion is about three-quarters of an inch in length, and is marrower than the cartilagious part. Its outer extremity is dusted and rough in the greater part of its circumference, for the attackment of the outling of the pinns. The inner end is less dilated than the outer, and is alsped, so that the anticior wall juts out beyond the posterior by about two lines: it is marked, excepting at its mapper part, by a narrow groove, for the insertions of the membrane tympani. The skin lining the auditory causalis, way thin, and closely adherent to the cartilaguasses and caseous portions of the tube. It is continued over the membrane of the tympanum in ing at any instances. It is not been added to serve the addition sense in easy thin, and closery the addition sense in easy thin, and closery the addition sense and caseous portions of the tube. It is continued cases the mentiones of the typeanum in the form of a kins politicle, forming its outer covering. Around the extense of the meature are some fine hairs, and there are also correspond a plants, which secrets ordines, and there are also once on the medical by separate ordines.

pharper by the Restachian tube. It is inswersed by a chain of small movable bones, which connect the mean trans-typicani with the labyrinth, and serve to convey the vibrations communicated to the membrane typicani screes the eavily of the typicanima to the internal ear. The cavity of the typicanima to the internal ear. The cavity of the typicanima to the internal ear. The cavity of the typicanima to the internal ear. The cavity of the typicanima to the internal ear. The cavity of the typicanima to the transverse, being a little broader behind and above than below and in front. The conter boundary of the cavity is formed by the securious typicani, and by a small portion of the supercading bene. This membrane is a kin semitation is a kin semitation of the capacidade of the typicanima from the bottess of the auditory canal. It is directed very chiqualy towards the auditory canal, its external surface being concave, as internal conver. It is composed of three layers, as already stated, is part of the integument liming the meatus. The middle layer is fibrous being formed of fibrous and clastic tissues, and fixed in the groove of the meatus. Some of the fibrous being formed of the meatus. Some of the integrand of the restact. Some of the integrating form near the centre to the circumference; others are arranged in the form of a dame circular ving treasurate the variety of the fibrous the form of a dame circular ving treasurates the variety in the servers. the meetes. Some Gruse intrearanges from seer upsecutive to the circumference; others are arranged in the form of a donse circular ring towards the mangin of the membrane. The internal inyer is innecess, being part of the mucous liming of the tympanism. The Eustachian tube is the channel through which air is conveyed from the pharynx to the tympanism. It is about an inch and a half in length, and is directed downwards and inwards to the pharynx. Like the meaning addicting it is nearly concerns and merity characteristics. downards and inwards to the puntying make each meature auditoring, it is partly osseous and partly cartilaginous in texture. The small bones or ossicles of the tympanum are three in number,—the malleus, incuand stapes. The malleus—so named from its fancied resemblance to a hammer—consists of a head, neet, and the control of the contro handle, and two processes, a long and a short. The inous—so called from its resemblance to an anvil, but which may rather be said to resemble a bicusped tooth, with one of the roots longer than the other, and bent to one side—consists of a body and two processes. The stapes is so called from its close resemblance to and a base. These small hones are connected together and with the tympanum by ligaments and moved by enually nucles. The handle of the mallens is attached externally to the membrans tympani. The head of the mallens articulates with the body of the incus. The malless articulates with the body of me mean. The shorter process of the incus is received into an aperture of what are termed the mastoid cells; the long process curving downwards and ending in a rounded convex point, where it articulates with the head of the stapes. This last has an incrizontal position, with the crurs or branches directed forwards and backwards, and backwards, the fractic oralis of the and its base is fixed over the fenestra ovalis of the internal wall of the tympanum. This is a reniform opening leading from the tympanum into the vestibale, the opening in the recent state being closed by the liming membrane, which is common to both cavities. The inner and fundamental portion of the organ of hearing is called, from its complexity, the labyrinth, and consists of three parts,—the vestibule, the semi-circular canals, and the oochles. It consists of a series of cavities channelled out of the substance of the petrous bone, communicating externally with the cavity of the tympanum and internally with the me auditorius internus, which contains the auditory nerve. Within the osseous labyrinth is contained the massbrenous labyrinth, upon which the ramifications of the auditory nerve are distributed. The vestibule is the common central cavity of the osseous labyrinth, and is placed behind the cochles but in front of the semicircollar canais. It is somewhat oval in form from being backwards, and measures about one-fifth of me is in different directions, but is marrowest. From withe inwards. In its americar wall is a large oval open the cartifuguration and concerportions of the dube. It is continued over the membrane of the tympanam it is continued over the membrane of the tympanam it he form of a tikin politicle, forming its outer covering.

Around the estimate of the membrane of the tympanam is superior walls are five openings, by which it commands to cate with the semicircular canals. These are three body canals standed above and believed the restriction cates with the semicircular canals. These are three car, wax, and open on the semicircular canals only canal situated above and believed the restriction. The middle car or tympanams is an integralar cavity situated within the petrous hone, and, interposed between the mealing auditorium and the acquire to the castillate of a care of the car These are three

tained within the dings and subdivides persund along the outer g about one-tenth of an liminishing to half that size tothe semicircular canals a hen, is lined with a thin fibrons the outer surface of which adheres closely is be sufer wifface of which adheres closely be, while the inner is covered with a single pitalities, like that on scross membranes, as all in scross fluid, called the layour co-stlyingh. This fluid fills the passages of the six maintenance structure are not subvisith, is maintenance structure from its limit membrane printly, and semisted from its limit membrane. as its a middle manuscus structure inclosed within the as hapyinght, and somewhat from its liming meaning the parilymph. It is confined to the vertibule manipular samals, laving the general form of the middle bony parts, and is compact of a closed structure of the complex form, containing a fluid the embodymph. That part of the membranous ack sessions of two d postions, which though closely connected in, appear to be distinct sees, the larger of the he missis or common sinus, being situated at show, appear to be distinct sees, the larger of the bake, appear to be distinct sees, the larger of the control at a part of the vestibule; the endule, is smaller and rounder, and is situated at the endule. I smaller and rounder, and is situated at the vestibule. Smaller nes, the saccule, is smaller and rounder, and is sta-d, is the lower and fore part of the vestible. Small issueds, masses or otoliths, consisting of minute maked and elongated grains of carbonate of lime, are make in the inner part of the wall of the utricle and because in the inner part of the wall of the uncere and because. The auditory nerve, which is distributed over the different parts of the labyrinth, enters by the measure auditorius internus, and divides into two branches; viz., an anterior for the cochiea and a pos-terior for the membranous labyrinth. The occhiea such divides at the base of the modiclus or axis into erous twigs that enter the apertures in that body, thence they are directed outwards. The vestibular the membranous labyrinth, and ramify themselves on the walls of the sace, some of the file filaments passing brough the otolith, others outside of it. The sense of aring is, strictly speaking, only a refinement of the see of touch. The impressions with which it is conrement arise wholly from peculiar undulations of the resticles of ordinary matter, propagated in obedience of the ordinary laws through the medium in which the is its sectionary laws through the unclum in which une minimal lives, and impinging more or less immediately again a sensitive part. The trumpet-like pinns or markets of the external car serves to collect the sound, which is then conveyed, by means of the meature andi-limits externity, to the membrana transpani. This is through into vibration, which is communicated to the malleria, and is carried by the incus and stapes to the less, and is carried by the incus and stapes to the measure of the fenestra ovalis. From this last the time is communicated to the various parts of the measurement showing the property of the manufacture start, and conveyed to the brain. The off the small calcareous masses in the sacs is to nightin the sucrous undulations, and to commutate to the nerves stronger impulses than the lymph as could impact. The range of hearing, like that tight, differs very much in different individuals. (See

Hills, et Ginx cont. Dan parl), an honorary title of distinction given to noblemen, who take rank between marquises and viscounts. The term originated with this nations of the north of Europe, who applied the little of "int" (pronounced yarl) to theftains of the highest rank, who were appointed by the sovereign to govern large tracts of land, having the powers of a viscouy as the administration of justice, but being also under the obligation of furnishing, equipping, and maintaining a certain number of men as a contingent to the mational force, and of soting as their leader when the necessities of war compelled the king to call them out for actual acruse. The dignity was, in fact, equipment among the Teutonic nations to that of the them out for actual service. The dignity was, in fact, equivalent among the Teutonic nations to that of the Roman serves, or count; and the appellation was the highest stile of honour that the monarch could confer it was introduced into England by the founders of the Saxon heptarchy, and then applied to the nobles generally, in contradistinction to the certs, who were free men, forming the large middle class of the Anglo Saxon instant The earls, who presided over the courts of justice and public meetings of the district or shire intended by the title of soldownen, were further distinctions to their management, were further distinctional of the title of soldownen, but this appellation used to their management, were turther distin-had by the title of soldownen, but this appellation making fell into disuse, and at the time of the Con-title Saxon governors of shires, whose rank was replant to that of the present lord leutenants of titles, were all styled earls. Among the most noted to powerful of the Anglo Saxon earls was Earl, white son Harold encanded and the Anglo Saxon earls was Early s powerful of the Anglo Saxon earls was Earl whose son Harold succeeded Edward the property of the English throne. Under William the sections were held by tenure, and the successed of local jurisdiction and power, and the claim to claim a certain portion of the local is wome of them, such as the earls of Chester, partiaments, created barons, and had their fatate like the king himself It remained the state like the king himself. It remained the te off sank in England until the latter part a century, when the dignities of duke and the infracticed, the holders of which took at the cart. The title, which is now granted beauty was formerly conferred by the king who lavested the earl, at his creation, with a settling on his avonet and and and the cart. ng on his coronet and garding on his

TALL OF BUGLAND, the title of one of the to power of granting armorial bear-ion in matters relating to pedigrees in arms, through the kings at arms, me, through the kings-warms, is Marroy, who act as his depu-tareditary, and attached to the Charles II in

ared to have pro to 1307, or during the reig Henry III., and Edward I fullest development about ti fallest development about the management tury. Some writers have proposed the architecture of the first part of Lancet, and that of the latter part at but it will be sufficient for general purpoit as the characteristic style of the life. this style the strength and solidity of An architecture was returned, but it was softened a dued by the introduction of more graceful for a greater degree of currenment. The heavy Anglo-Norman columns were replaced by infinite more elegant shafts, having the appearance of se of small columns clustered together round a se s, and the semicircular arched and windows was replaced by one of a pointed or land shaped form. Sometimes two or three of these pour shaped form Sometimes two or three of these paid lights were grouped together, separated only by has piers When three were thus brought together, centre light was considerably higher than those either side, and in any case a continuous moul surmounted the whole of the arches In the latter of this period two or more lancet-pointed window were often surmounted by an arch of the same form pierced with a cusped circle, or with trefolls and quet foils, and this led to the elaborate tracery that man the windows of the Decorated period The doors were deeply recessed, and the sides of the splays were adorned with deeply-cut mouldings, they were also surmounted with a dripstone or moulding prof from the wall, and springing from carved be corbels The buttresses were narrow, but projected corbets The buttresses were narrow, out projessed to a great distance from the walls, they were also divided into two or three stages, each projecting less than the one immediately below it Flving buttresses were also introduced, and string courses were commonly used The walls were ornamented with disper-work, the surface being carted or painted with a small regular pattern, generally of trefoils of quatrefoils. The capipattern, generally of trefoils of quatrefoils. The capitals of columns were bell-naped, swelling outwards from the shaft, with an horizontal section similar to from the snart, with an interest when were carred with iolinge boidly rendered. The roofs were sasep, and for the most part open, some, however, were vaulted and ground fallabury Cathedralis considered the best example of this style of architecture, as it belongs wholly to the Early Frighish period, and no other style is consequently found in combination with it. Parts of Westminster Abbey, Lincoln, Wells, and Hereford cathedrals, and York Minster, are also built in this style. In Plate XLVII, figs 1 and 2, are given two examples of the Early English style of architecture, and at fig 1, Plate XLVIII, an example is presented of an Early English window.

Exensel, or nest (Sax cornest or geornest, Lat. arche, whence, in Scotland, it is called arles), is something given in order to bind a bargain,—usually shall sum of money. It is also applied to any simple execution of the same and a second of the same and the second of the same and the same of money. that of the shaft steelf, and sometimes they were carred

thing given in order to bind a bargain,—usually a sum of money. It is also applied to any simple a mony for the same purpose. Audiently, among all northern nations, shaking of hands was held necess to bind a bargain, a custom, say Blackstons, why we still retain in many verbal contracts. A sale is made was called hand-sale; and in process of sime same word was used to signify the price or same which was given immediately after the chaking hands, or instead thereof. By the sivil law, her recedes from his bargain loses his carnest; and it person who received the earnest entire, he made was the carnest and the carnest double. By the law of England, however, the carnest double. By the law of Em if any part of the price be paid down a any portion of the goods delivered and the agreement, and attended to the large person is obliged, in a real factors. This officer was styled by his bergen; and in case he decline the state of the colors was styled by his bergen; and in case he decline the state of the state of the state of the whole amount.

emitical, as in the shall of a sociation for example, the host is from to increase to the state of 1 Tabraham for example, the host is from to increase to the state of 1 Tabraham for the first over 15 or 21 yarder for it is not at all certain that this would be found to be a fixed law, and that the heat would increase in this latio as we approached the centre of the Earth, if it were possible to do so.

approximent the center of the means, it is more powerful to 60 so.

ERREMENTALE, erth-spair (Ang.-Bex.), file general name given to all atensits mean of day, which may be divided into three classes;—first, pottery, consisting of jugs and pass of a coarse description, red and brown in colour, that are made of a sommed not have in colour, that are made of a sommed hand of clay; secondly, porcelam, or vessels made of a reyr fine clay, with which a preparation of first a mingled that fuses when the article is subjected to great heat and smalgamates with the stay, which will not melt, rendering the vessel seam; transparent (see Porcelam), and thirdly, the ordinary household ware, made of various kinds of clay that burn white, which differs from porcelain in being completely opaque, and to which the term eartheuwire is more properly applied and limited. The clay that is priscipally used in the Staffordshire potteries considerant in the manufacture of porcelam, and known as China the clay that is priscipally in Comment. cipally used in the Staffordshire potteries consil from Dorsetshire and Devonshire. The finer clay used in the manufacture of porcelam, and known as China stone, China clay, and kaolin, is found in Corawall, principally in the neighbourhood of St. Anstell. It consists chiefly of disintegrated grante; but the shareful excellence of the, as well as of the Devon and Dorset clays, consists in its freedom from any impregnation of iron. To obtain the soft clay, large square pits are sunk in the earth, under which it has been assortished by boing that a stratum of clay hes. The sides of the pit are kept from falling in by a sheeting of boards and laggots, sustained ity transverse beams running from side to side, there after there, so that the interior looks like a network of wood. The clay is cut in ready cubes neasuring about eight or nine inches every way; these blocks are then taken to the drying-yard, where they are attacked in large sheds, and allowed to dry before being removed to be shipped for the Potteries. The China stone of Corawall is hard enough to be regularly quarried. The process of making surfiberaries the Potteries is as follows.—The clays is action—the ware at the Potteries is as follows.—The clays is caused with water, generally by means of machinery, until it assumes the consistency and appearance of cream; it is then filtered through fine sever until the mirature into this have been heated to reduces and calcund by being thrown into cold water, after which they are broken and ground to a fine nutrit with a addition increases as we approach the poles, and that the distance from the Earth's centre must consequently believe. The density, or specific gravity, of the Earth is the constant of the mixture is the same size, the weight of a equal sulfief water, that is to say, if we could compare assertly the same size, the weight of the Earth would be feet times as much as that of a sphere of water exactly the same size, the weight of the Earth would be feet times as much as that of the water. This was employed to be the case by Newton, and his supposed to be the case by Newton by the case of the later. This was a much and the case of the later by the case of the later his known, and his supposed to the potential parts of the supposed to the potential parts of the

epindle in the latte. The rest of the process is similar to that of throwing. The pieces are then placed in boxes made of fire-clay, called "segara," and baked in a kiln for about forty-eight hours, a gentle heat being applied at first, which is gradually increased in intensity until it becomes very great. After baking, the ware is called bisentle, and it is then ready for the final processes of colouring or printing, and glazing. Painting in various colours is confined entirely to porcelain and the better and more expansive kinds of earthenware. The common yellow were is ornamented with rings, spots, and wavy stripes of blue and white, by allowing colouring matter to fall on them from perfected funinel-shaped vessels while the article is reviving on the latte. The coarse blue pattern reasmbling sea-weed is produced by striking a brush charged with colour smartly against the vessel. When the water is printed, the pattern is first engraved on copperwarels printed, the pattern is first engraved on copper-plates, from which impressions are taken on very thin paper in the desired The paper is laid on the ware while the impression is rubbing the back of the paper lightly with a piece of cloth rolled tightly together. The paper is removed by soaking the article in water for a short time, after which the paper readily comes away, leaving the pat-tern printed in colour on the ware. The last process tern printed in colour on the ware. is that of glazing, the glazing matter for common ware being made of a mixture of litharge and calcined flint, and the better sorts, of a compound of lead, flint, glass, and sait reduced to a state resembling thin cream and sait reduced to a state resembling thin cream.
After the ware has been dipped in this mixture, and
wetted theroughly all over, the articles are again placed
in the acgaza, and subjected to heat just strong enough to
fuse the glaze, which produces the smooth, transparent,
polished coating with which our various household utensils in earthenware are covered, and without which they would be rough to the touch, and liable to absorb oil and greasy matter, so that it would be consequently impossible, or at least a matter of difficulty, to keep them in a state of clembiness. An historical sketch of the rise and progress of the potter's art, and the best and most remarkable kinds of earthenware that have been produced at various periods, will be found else where. (See Porren's ART; Majolica, Palissy, and WEDGEWOOD WARE.) It is only necessary to observe here, that although we may be surpassed by China and other nations in the production of the more beautiful corts of porcelain, yet the solidity, strength, resistance to the action of fire, and the cheapness of English earthenware, have rendered it an article of commerce that is exported to every part of the world, and is pur-chased in preference to that produced in any other country.

EARTH HOUSES, recesses in the earth, so called in Scotland, which seem to have been small natural caverns, or artificial chambers hollowed out to serve as a hiding place in time of war for men and property, or as storehouses for corn and provisions for the winter. They are generally long and narrow in form. the largest being about 10 feet wide, 50 feet long, and 6 or 7 feet high. The sides are formed by a wall of sough stones, and the earth above is sustained by a ceiling of undressed slates or flag-stones, the ends of which are supported on the side walls. The entrance is small and near the top, and constructed in such a manner that it could be easily masked if necessary. When the floor was wide, the walls were brought closer specified beyond the one below it, until the interior assumed somewhat of the form of a vaulted passage. They are not far below the surface of the earth, and ings are not far below the surface of the earth, and are generally found in dry situations in the side of a hill or cising ground. Remains of various kinds have been found within them, which shows that they were used as temporary retreats, if not as permanent places of abode. Decasionally two or more chambers are found communicating by a small passage. These curious underground chambers are sometimes called

frequency and violence usem to be consrected with the intensity and activity of the volences near them. Rearly all volence phenomena are excompanied by trembing and shaking of the earth in the signeent districts. On many occasions they precede volence emptions, and cease as soon as the truption takes place. It is singular, however, that the most severe earthquakes take place in recome for reward from volumes; and take place in regions far remote from volcances; and districts in which there are the remains of extinct vol-cances are not more liable to earthquaires than other places. Egypt has been more exampt than, perlaps, any other country; but an earthquake countred there in 1740 A.D. They sometimes happen in the middle of the ocean, and cases have countred where relamine islands have been thrown up, and afterwards have disappeared. It has been calculated that not less than twelve or thirteen earthquakes, destroying both life and property, happon every year. When they life and property, happen every year. When they occur severely, there is, first, a trembling; then a severe shock, or a succession of shocks; then a trembling again, which gradually dies away. The most violent shocks are instantaneous, and there are seldom more than three or four. When there is more than one violent shock, there are smaller sheeks or trem-blings between. Sometimes whole cities have been one violent shock, there are smaller sheeks or treen-blings between. Sometimes whole cities have been destroyed by an earthquake, and sometimes fer-tile districts, with all their fruits and produce, have been laid waste. At the great earthquake of Lisbon, 60,000 human beings perished; and in Calabria, at the end of last century, 40,000 persons dost their lives in a similar manner. It has been exiculated that at least shirteen millions of the human race have thus been destroyed. When an earthquake occurs, observers destroyed. When an earthquake occurs, observers state that the shock has at first a distinct vertical state that the shock has at first a distinct vertical direction, coming from below upwards, but afterwards the direction of the motion becomes gradually more horizontal, till it ceases. This motion is evidently caused by an earth-wave, or undulation of the solid crust of the earth. In the case of the earth-galace at Lishon, before mentioned, the course of this wave was acceptly absoluted. roughly calculated. It must have moved very rapidly, not lasting at any point more than a second of time. The extent of area over which its influence was felt was very great. To the north, it was felt on the southern shores of Finland, and towards the west, beyond the St. Lawrence in Canada, and also in the West-India islands. The whole area affected could not have been loss than whole aren affected could not have been less than 7,500,000 miles! The raising of the earth over such a vast surface of course affected the sea; and the wave thus formed attained a height of sixty feet at Cadra, passing far beyond the ordinary limits of the tide. There are a great number of theories propounded in order to account for earthquakes; but they all agree in tracing them back to volcanic agency. The starting-point of all is the acknowledgment of the existence of a molten fluid mass in the interior of the earth. generation of immense volumes of elastic gases under the influence of the heat of this mass, would necessarily result in an explosion, which would account for many of the earthquakes which occur. At a meeting of the British Association, Mr. Mallet proposed an ingenious theory. Assuming that the lines or centres of volcanie action are not far removed from the sea, he argued, that when an eruption takes place under the surface of the water, an opening or fissure results. Through this the water would descend to the central fire. Arriving there, it would take the spheroidal form until the surface with which it was in contact was cooled, when an explosion would take place amply sufficient to cause an earthquake. The latest theory of earthquakes is that of the brothers Rogers, who state that the producing cause is an actual pulsation of the molten fluid mass in the interior of the earth. This pulsation is carried forward in the shape of great waves, from large rup-tures caused by the tension of clastic matter, bearing been found within them, which shows that they were used as tempowery retreats, if not as permanent place in and the programment of the of abode. Consistently two or more chambers are found communicating by a small passage. These curious underground shambers are sometimes called Ficts houses.

Exempovers, seth tweet [5ax, cwacian, to tremble), a term applied to say shaking or tremor of the outer surface or solid crust of the globe. No part of the set is the feel them. They are, however, most the set is the registrostrood of volumoes, and their of level plains. The mysterious nature of earthquakes and superalent in the neighbourhood of volumoes, and their

is an incentive to their study; but every attempt at explaining their origin must be, at the best, theo-

EARTH'S CRUST. (See Grology.)
EARTHS (in Chem.).—The earths proper are ten in EARTHS (In Chem.).—The energing proper are ten in number,—alumina, gluoina, giconia, thorina, yttria, erbia, terbia, ceria, lantania, didymin. They are distinguished by being soluble in water, but dissolve in caustie sikalies and their carbonates. They are all oxides of metals which do not decompose water. Many of them have been but imperfectly examined many or them nave been but imperieurly examined, owing to their extreme rarity. Alumina, a constituent of all clays, and glucina, found in the emerald, are the most important. Alumina, by its isomorphism with sesquioxide of iron and other peculiarities, connects the earths with the oxides of the heavy metals.

the earths with the Oxides of the heavy metals.

BARTHS, ALKALINE. (See ALKALINE BARTHS.)

BARTH-WORES, in Mil., intrenchments hastly thrown up, consisting chiefly of a rampart and ditch, and serving as temporary lines of defense. At the siege of Sebastopol, the southern side of the city was mainly defended by earth-works of great extent, size, and strength; and from this circumstance it is now considered that works of this kind are as serviceable as those of stone for permanent defences, and have the double merit of being less dangerous to the defenders, since no splinters of stone can fly about, as is generally the case when a block of granite is struck by a cannon-ball, and more easily repaired. It is not, however, likely that earth-works will supersede ramparts of stone against the heavy artillery that is now coming into use, but that our stone walls, like the sides of our vessels, must be rendered better able to resist the "cheavy brunt of cannon-ball" by being coated with

armour-plates of iron. EARTH-WORM (Ang.-Sax.) (Limbricus, Linn.), a well-known annelide. Its outward appearance is a body composed of numerous narrow rings closely approximated to each other; the colour of the body is reddish, or purplish; of a cylindrical form, some-what pointed at the anterior extremity, and usually a little flattoned at the tail. It is without the organs of little flattened at the tail. It is without the organs of sight. The organs of motion consist of a double row of bristles running down the lower surface of the body, and which are capable of being withdrawn within small hollows when not in use. The mouth is unsarmed, and the intestine runs straight through the body. The running along the ventral and dorsal regions of the body, and united by numerous branches. The blood is red. Like the leeches, this worm is furnished with ciliated canala, which have been supposed to serve as organs of respiration; but their real destination appears to be still uncertain. As far as relates to its appearance above the ground, the earth-worm may be regarded as a nocturnal animal. In the night and at early morning, hundreds may be seen in localities where, during the daytime, not one is to be seen. They are of immense utility in improving the soil. The organs of the earth-worm's locomotion prevent its moving backwards, whilst the expansion of the rings, as it contracts the anterior segments and draws forward the hinder parts, widens a passage for it through the earth, whose particles were close together before. They are thus, in their multitudes, of incalculable utility an constantly loosening and stirring the soil, and accumulating on the surface those little hillocks of earth known as "worm-casts." On this subject Mr. Charles Darwin, who seems to have given it long and careful attention, remarks: "The burrowing of earthworms is a process exceedingly useful to the gardener and agriculturist; and these animals are far more bene-licial to man in this way than they are injurious by devouring the vegetables set in the soil. They give devouring the vegenous sees in beaut. They give a kind of under-tillage to the land, performing the same below ground that the epade does above the garden, and the plough for arabic land; and loosening the earth so as to render it permeable to air and

farmers to the working down of the materials in question, is really due to the action of the earth-worms, appears from the fact that in the soil thus formed large numbers of worm-casts may be distinguished. large numbers of worm-casts may be distinguished. These are produced by the digestive process of the worms, which take into their intestinal canal a large quantity of the soil, through which they burnow, extract from it the greater part of the vegetable matter it may contain, and eject the rest in a finely divided condition. In this manner a field manured with manual has been considered. with marl has been covered in the course of eighty years with a bed of earth averaging thirteen inches in thickness." Besides their usefulness in the manin thickness. Hesiaes their user ages in the manner above described, the earth-worms are of importance as food for birds, fish, &c. Their value as beit for fishes is well known to evey angler. The power of reproducing parts after mutilation is very great in this animal, as in the whole of the order. It is generally this animal, as in the whole of the order. It is generally supposed that the earth-worm may be propagated by division; but this searcely appears to be the case. It is said, however, that if it be divided across the middle, the part bearing the head will develop a new tail, although the tail will soon die; and that if the head be cut off, the body will form a new head; but it appears that both portions never survive the mutilative.

EASEL, e'-zl (Ger. esel, an ass), a frame on which a painter supports the cauvas on which he is working, in a slightly slanting position. It consists of three long legs councided by hinges at the top; which extend and form a tripod. Holes are bored in the faces of the two legs against which the painting rests, in which the two legs against which the painting rests, in which pegs are inserted, which support the picture, and afford the means of raising or lowering it to the height and position that may be desired. Easel pictures, among painters, are the smaller pieces which are painted on the easel, as distinguished from those which are drawn upon walls, ceilings, &c. East, cest (Sax. east, Ger. ost), the quarter of the heavens or point of the horizon where the sun rises at the courses in March and Santarnhar. When we

the equinoxes in March and September. When we are looking towards the north, the east is on our right hand and the west is on our left; and vice verse when when we look towards the south. The east may be pretty nearly determined, and from that the other points of the compass, by calling to remembrance the point of the horizon in which the sun rises, making due allowance for the time of year; and if we are near a church it is still easier, as it is a fixed rule to build a church in such a manner that the chancel and communion-table is at the east end of the building, or points directly towards the east.

EASTER, cest'-er (Sax. castre), a feast held by the Christian church in commemoration of the resurrection of our Saviour. It is a movable feast, occurring at any date between March 21 and April 25; and by it the other movable feasts throughout the ecclesiastical year are regulated. It is held about the same time as the Jewish Passover, or Paschal feast, although it very seldom happens that the Christian and Jewish featurals are observed on the same day. In the Greek and Latin churches Easter is still called Pascha, from the Jewish name for the feast of the Passover. The term Easter has been derived from various sources; some taking it from the Saxon osier, 'to rise,' and others from the name of a heathen goddess, Eostre or Ostara, whose rites the Saxons were accustomed to celebrate at this time of the year, and on account of which the month of April was styled Eostermonath in their calendar. It was a period of rejoicing with them, on account of the return of spring and the renewal of vegetation; and the name and the accompanying simple ceremovies that attended the festival, such as lighting fires, &c., were easily adopted by the Christian church in Britain, which taught that it was to be observed as a season of rejoicing, as it was held in commemoration of the resurrection of our Saviour. In the early church this garden, and the plough to arrange and; and mosening resurrection of our Saviour. In the early church this the earth so as to render it permeable to air and festival lasted for some days, and catechumens were add to the depth of soil; covering barren tracts with a layer of productive mould. Aftau, in fleds which have been overspread with lime, burnt mark, or cinders, these substances are in time covered with finely dither the substances are in time covered with finely divided soil well adapted to the support of vegetation. Catholic column it is time of eight of column to the finely divided soil well adapted to the support of vegetation.

commonly interchanged in families and among friends in Russia and all countries in which the Greek faith is In Resea and an countries in which the Greek islin is established. There were many popular observances of Easter in various parts of England; such as eating tansy cakes and puddings; but these have fallen into disuse, although many still make a practice of wearing some new article of dress for the first time on Easter some new article of dress for the first time on Easter Suuday, alleging that it is unlively not to do so. In determining the day on which Easter is to be held, the council of Nice, in 325, decided that it was to be celebrated on the Sunday following the 14th day of the first month of the Jewish year, on which the Latin or Western church had been accustomed to hold it; and on the introduction of the Gregorian calendar, a table was constructed, based on the Metonic cycle, by which Easter was to be found, and which the Church of England still uses. In the Book of Common Praver, we are told that "Easter Day is always the First Sanday after the Full Moon, which happens upon or next after the Twenty-first Day of March: and if the Full Moon happens upon or sunday Easter Day is the Sanday Woon happens on a Sanday, Easter Day is the Sanday after the Iwenty-Inst Day of March; and it the Idn Moon happens on a Sunday, Easter Day is the Sunday after." Now the moon above alluded to is not the moon of the heavens or the mean moon of the astronomers, but an imaginary moon, the movements of which follow the movements of the real moon by an interval of a day or two. Therefore, when "full moon' is spoken of in the directions regarding Easter given above, we are not to take it as the time when the moon is at the full in the heavens about this period, but the 18 at the full in the heavens about this period, but the 14th day of the imaginary moon of the calendar, which falls upon or next after March 21 in any year. To find this 14th day, or "full moon," of the calendar, and consequently Easter-day, we must have recourse to the table below, taken from the Prayer Book. Having found the golden number for the year (see Golden Numbers), look for it in the first column of the table; and the date which is in a line with it in the second column, is the day of the full moon of the second column, is the day of the full moon of the calendar. Next find the Sunday or Dominical letter for the year (see DOMINICAL LETTER), and the date which is opposite the first occurrence of the Sunday letter in the third column, reckoning in all cases from that letter in the column which is in a line with the date of the full moon already found, will give the day of the month on which Easter Sunday falls. If the Sunday letter is the same as that which is in a line with the date of the full moon, as it happened in 1562, Easter Sunday will be seven days after, as the coincidence of the Sunday letter and the date of the full moon in the same line shows that the full moon of the calendar falls on a Sunday.

Oold. Num.	Days of the Month.	Sun. Let.	Gold. Num.	Days of the Mouth.	Sun. Let.

To explain the manuer in which the above table is used, let it be required to find Easter Sunday for 1863. For this year the golden number is 2. The date in the this year the golden number is 2. The date in the wecond column, opposite the number 2, is April 2; this, then, is the day on which the moon of the calendar is supposed to be full. The Sunday letter for the year is D. Reckoning, then, from A, the letter in a line with the date of full moon, we proceed down the column antil we come to D for the first time, in a line with

which we find April 5 in the second column, the day on which Easter falls for the year in question. The above table is available in finding Easter for any year from 1700 to 1809 inclusive. To make it available for any year between 1900 and 2199 inclusive, every numany year between 1900 and 2109 inclusive, every number in the column of golden numbers must be shifted into the line immediately below it, except 17 and 6, which remain where they now are.—Ref. Companion to British Almanac, 1845; Eng. Cyc.—Arts and Sciences.

EASTER OFFERINGS, or EASTER DURS, are small sums commonly paid by each person when he receives the Lord's supper at Easter to the elergyman. They

are generally twopenee from every communicant, and are due of common right, and not by custom only.

EAST-INDIAN AEMY.—As the possessions of the East-India Company increased in India, it was found necessary to raise and maintain a body of troops to enable the Company to preserve its own by force of arms. At first a few Europeans, mostly men of despected for the contract of the company to preserve its own by force of arms. perate fortunes, under the command of some adventurer as reckless as themselves, garrisoned the forts that were erected for the protection of the merchants' fac-tories; but ere one hundred and fifty years had elapsed from the date of the grant of the first charter, these little bands of men had grown into regiments and armies. and the Company was actively engaged in carrying on wars with the French and many of the native princes. Liberal pay, ample furloughs, and pensions after serving for a certain period, formed attractions which brought the natives to the Company's standard. A system of organization was introduced, a few regiments of Europeans were enrolled and dispersed among the native forces; and in 1857, at the commencement of the Indian mutiny, the armies of the three presidencies,— Sudan mutary, the armies of the three presidencies,—
Bengal, Madras, and Bombay, amounted to about
280,000 troops of all arms of the service, including
18,000 European troops in the Company's pay and
about 24,000 of the queen's troops, who were also paid
by the Company while in India. Besides these, there
were large contingents furnished and maintained by were large contingents furnished and maintained by the native princes under British protection. Since the close of the mutiny, the power of the Company has passed into the hands of the Crown, and the European portion of the Company's troops has been amalgamated with the British army. (See Army.) The native por-tion has been entirely reorganized, and is quite as nu-merous as it was before the commencement of the outbreak, but perhaps more efficient and more under the control of its officers.

EAU DH COLOGNE, o-de(r)-ko-lone' (Fr., Cologne-water), a perfumed spirit, originally manufactured at the town of Cologne, in France, and generally used as a perfume, although several imaginary medical virtues

a pertune, a mough several magnary medical virtues in popular belief are attached to it.

EAVE, eecc (Sax. yfee), in Arch., that portion of the roof which projects over and beyond the face of a wall, to carry off the rain and prevent it from trickling down

its surface and rendering it damp.

EAVESDEOF, eevz'-drop (Lat. stillicidium), is the water which drops from the caves or roof of a building, or the space left outside the walls of a house for the rainwater to escape. Among the Romans, unless a man had a servitude of stillicidium over his neighbour's property, he was obliged to keep at a certain distance within his own in building; for no one was obliged to receive on his own property the water which fell from his neighbour's bouse. Laws to the same effect exist. receive on his own property the water which fell from his neighbour's house. Laws to the same effect exist in most modern countries. The space is commonly regulated by usage, and may be usually from a foot to a foot and a half on the several properties; but a propertieor may build as near his own boundary as he pleases, provided the rain descending from the roof fall within his own property, because in this way he is only making a natural use of what belongs to himself, without exceptions with a prighthouse weaponts.

EAVES-DEOFFESS (Ang.-Sax.), in Law, are such as to hearken under walls or windows, or the caves of houses, to hearken after discourse, and thereupon to frame slanderous or mischievous tales. Such persons are regarded as a common nuisance, and may be indicted at the quarter sessions, and punished by fine, and obliged to find sureties for their good behaviour.

Eng. eb (Sax. ebbe), the reflux or return of the tide towards the sea after high water; opposed to flood, or

## Ebenaces

Ecchymosis

EHERACEE, eb-en-ai'-se-s (from Arab. abnous, Lat. chenus, Sp. chano, ebony), in Bot., the Ebony fum., a nat. ord. of dicotyledonous plants, in the sub-class Corolliflora, consisting of about 160 species, mostly natives of tropical India. Character.—Trees or shrubs with alternate, entire coriaceous leaves, without sti-pules. Flowers, polygamous; calyx 3—7-parted, in-ferior, persistent; corolla 3—7-parted; stamous equal in number to the divisions of the corolla, or twice, or four times as many, and attached to the corolla, or hypogynous; anthers 2-celled, introrse, opening longi-tudinally; overy 3-12-celled, each cell with one or two ovules suspended from the apex; style usually having as many divisions as there are cells to the ovary. Fruit fleshy; seeds large, albuminous. Many of the Ebena-cea are remarkable for the hardness of their timber, which is known under the names of ebony and ironwood. Many species have edible fruits, and some have astringent barks. (See Diospynos.)

EBIONITES, eb'-e-o-nites (Heb. ebion, poor, low; used

by the Jews as a term of contempt), a sect of Jews who professed Christianity to a certain extent, and seem to have consisted of two different classes, the first of which was to be found in the Holy Land in the 1st and 2nd centuries of the Christian era; while the lat and 2nd centuries of the Christian era; while the second existed in Syria, especially in the neighbourhood of Bercea, at the latter end of the 4th century and the beginning of the 5th. The early Ebionites denied the divinity of our Saviour, believing him to be a mere man, the son of Joseph and Mary, but considering him to be the Messiah, allowing the truth of his resurrection from the dead, and looking for his second coming to restore the Jewish kingdom upon earth to a coming to restore the sewish ringdom upon earth to a greater state of splendour and power than it had ever hefore enjoyed. They seem to have been a moral sect, adhering to the Mosaic law. They acknowledged the scopel of St. Matthew only, but struck out all parts which related to the divinity of our Saviour. The later Ebionites were distinguished from these by allowing the supernatural birth of our Saviour, although they did not believe in his pre-existence as the second person of the Trinity. They also used the Gospel of St. Matthew, but rejected the Acts of the Apostles and the Epistles of St. Paul.

Ebonits, eb-o-nite (Lat. chemis, chony), a substance

Enonite, eb'-o-nile (Lat. ebenus, chony), a substance produced when caoutchoue is mixed with from two to ten per cent. of sulphur, and raised to a temperature of 270° to 300°. The caoutchoue undergoes a change, it acquires new characters, its elasticity is increased, and it becomes more equable. The ordinary solvents do not affect, nor does cold or heat alter, its general conditions. (See VULCANIE.)

EBONY. (See DIOSPYROS, EBENACE.E.)

EBULLITION, eb-ul-light-un (Lat. ebullifio, a bubbling un), the bubbling agitation of liquids after they have

up), the bubbling agitation of liquids after they have been heated to their boiling-points (which see). On gradually heating water in a glass flask by means of a spirit-lamp, we first observe the formation of minute air-bubbles, which dart through the liquid with great rapidity. As the temperature increases, these give place to larger bubbles, consisting of steam, which are formed at the bottom of the vessel, and which rise a little mar in the liquid and these gives the state of the stat little way in the liquid and then contract and disappear, producing a hissing or simmering sound. as the heating goes on these steam-bubbles rise higher and higher in the liquid, until at last they reach the surface and escape, when the liquid is said to be in a state of ebullition. The temperature at which the chullition of a liquid takes place varies with the pressure of the atmosphere. When the barometer stands at 30 inches, water begins to bubble at the temperature of 212° Fahr., because at this temperature the elastic force of steam will support thirty inches of mercury, and consequently the bubbles acquire the power of breaking through the surface of the heated liquid.

ECHALIUM, ek-bai'-le-um (Gr. ekballo, I cast out, ex-pel), in Bot., a gen. of plants belonging to the nat. ord. Cucurbitaceæ. The species E. officinarum is commonly called the squirting cucumber, from the fruit sepa rating, when ripe, from its stalk, and expelling its seed and juice with much violence. It is a native of the south of Europe, and is cultivated in England. The feculence deposited from the juice of the fruit, when dried, constitutes the drug called elaterium, or extract of elaterium, which is a powerful hydrogogue cathartic. It is given when pure in doses of from 1/2th to 1/2th of a grain. In improper doses it is an irritant poison. Elaterium owes its properties to a bitter principle, named elaterin.

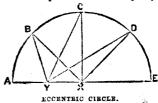

named etaterin.

ECCE HOMO, ek'-se ho'-mo (Lat., behold the man), a term in Art applied to those pictures which represent Christ wearing the crown of thorns, and bound ready for execution. Some of the greatest painters have employed their highest efforts upon this subject. The finest Ecce Homo in existence, without doubt, is that painted by Correggio, and now in the National Gallery in London. In this magnificent picture the noble features London. In this magnificent picture the mole features of the countenance of Christ express the utmost pain without being disfigured by it. The Virgin Mary is also represented, fainting in the arms of Mary Magdalene. The effect of the pale countenance of the Virgin is enhanced by the contrast of the dark blue clouk, which is drawn over her head like a veil. The picture has, however, suffered a little from cleaning and repairs. It is generally supposed to have been

and repairs. It is generally supposed to have been painted by Correggio at the age of twenty-six. ECCENTRIC, et-sen'-trik (Lat. eccentricus, from ex, from, and centrum, centre), in Mach., a sort of whoel, or revolving disc, in which the axis, or centre of motion discent expert engineers. tion, does not coincide with the geometrical centre. There are a great variety of eccentrics, and they are very useful in converting one kind of motion into another. By this means, continuous circular motion can be converted into alternating or intermitting rec-tilinear motion, or into curvilinear, but not rotary mo-tion. Eccentrics may be driven by straps or bands; the bands, however, require to be extremely elastic, or it is necessary to apply a stretching pulley or roller, which can be pressed against the strap by the action of a weight. By this means a uniform degree of ten-

sion is attained.

ECCENTRIC CINCLE According to the Ptolemaio system of astronomy, every heavenly body was supposed to move round the earth, as the centre of the universe, in a circular orbit, and at a uniform rate of speed. When it was found, however, that the appaspeed. When it was found, however, that the apparent orbits of the heavenly bodies were not circular, and that they moved through unequal spaces in equal times, they accounted for it by supposing that the earth was situated in a position which did not coincide with the centre of the orbits of the bodies that were revolving round it, and in this manner they attempted to reconcile the discrepancy between the apparent mo-tion of the sun and planets and the theory they had in-

vented with regard to them. Thus if AB, BC, CD, DE, represent equal portions of the orbit of any heavenly body moving in a circle, which portions are traversed by that body in equal periods of time, the motions which appear circular and uniform to an observer at X, the actual centre of its orbit, will not appear so to an observer at X, because the angles at X, which to an observer at 1, because the angles at 1, which the arcs subtend, are not equal, as is the case with the angles at X, which are subtended by the same arcs, and the heavenly body will consequently appear to the observer at Y to describe equal spaces in unequal times, and vice tersd. The orbit of a revolution of a heavenly body is therefore called an eccentric circle in the Bridgenic average heaven the earth round cle in the Ptolemaic system, because the earth, round which it revolves, must be considered to occupy a posi-

which it revoives, must be considered to occupy a posi-tion that is out of, or removed from, its centre. ECCHYMOSIS, ek-ke-mo'-sis (Gr. ek, out of: chumos, juice), in Surg., is a discoloration of the ekin, occa-sioned by the rupture of blood-vessels and extravasa-tion of blood, usually produced by fulls, blows, sprains, and the like. One of the most common examples of ecchymosis is a black eye. In general, the discolora-tion does not take place till some time after the recent

### Reclesiastes

of the injury; and if may usually be much diminished by the speedy and continued application of cold wet cloths to the part.

ECCLESIASTES, or THE PRECHEE, ek-kie-re-di-teer, is the name of one of the canonical books of the Old Testament, placed after Proverbe and before the Song Testament, placed after Proverbe and before the Song of Solomon. These names are a translation of the Hebrew title Echeleth, the former of the two being adopted from the Greek Boptuagint. There is no room to doubt the canonicity of this book. It has occupied a place in the Jewish canon from the earliest times, and has been universally received by the Christian church. From some passages in the Talmud, however, some seem to have questioned the expediency of ulacons it among the Scribtares that were read publications in a mong the Scribtares that were read publications in the Scribtares that were read public to the service of the placing it among the Scriptures that were read publicly, on account of its containing "words tending to heresy" and "words contradictory to sash other" According to tradition, this was among the Scriptures which were not allowed to be read by any one under the age of thirty. Numerous questions have been started regarding the authorship, date, design, and plan of this book. Many critics contend that it could not have been written by Solomon, which is the generally received opinion, on account of numerous foreign and modern words that occur in it. In favour, however, of the common opinion, there is the unqualified testimony of the book itself, the author speaking of himself as the son of David, king of Israel, and the greatest possessor of wealth and wisdom in Jerusalem. The long intercourse of Solomon, too, with the representatives of foreign natious, and his foreign wives, would necessarily lead to the introduction of numerical states. rous foreign words and phrases in his writings. The book is generally believed to have been written in his old age, after he had experienced all the pleasures and follies of life, and was able to testify to their being all vanity and veration of spirit. The plan and scope of the book are very obscure, and have given much trouble to commentators. Some have regarded it as a series the book are very obscure, saumers, so the commentators. Some have regarded it as a series of dialogues and disjointed narratives, rival poems, literary discussions, ethical aphorisms, and unfinished practical essays. The most plausible ground for regarding it as the work of a variety of authors arises from the frequency and abruptness of its transitions. and the apparent want of any fixed plan. The great theme of the book is the vanity of all earthly things and labours: with this it begins, and with this it closes. It is as far removed as possible from the character of a formal treatise,—being the confessions of a man of wide experience, of his searches after truth and happiness, of his many disappointments, and of his ultimate success. According to Dr. Davidson, the contents are comprehended in four discourses. The first discourse is filled with melancholy, doubt, and dissatisfaction. The course of cartly things is unalterably fixed, and consequently all our efforts to obtain happiness by the acquisition of wisdom and the pursuit of pleasure are unsatisfactory, leading to the conclusion that the object of life ought to be the enjoyment of the good things that are within our reach (chap. i., ii.). The eccond discourse begins with a description of the absolute dependence of man on a higher immutable Providence; that the cheerful, undisturbed enjoyment of life comes from the hand of God; and that it is vanity to suppose from the hand of God; and that it is vanity to suppose that man, though possessing wisdom, can procure it by his own efforts. Yet God, who has connected everything with time and circumstance, disposes of events rightly and well,—this very limitation to man's effort being intended, for the purpose of teaching him to fear God (iii. 1—v. 19). But it is the lot of many men not to enjoy the good things of life which they have acquived; and this idea, which is started in the close of the second discourse, becomes the leading subject of the third. Though the enjoyment of the possessions acquired through the favour of God is often thwated. acquired through the favour of God is often thwarted, man should endeavour to attain to the true and contented experience of life by cheerfully using the earthly things given him, exercising true wisdom, and avoiding the folly which is so common (vi.—viii. 15). In the fourth discourse, the mystery that it sometimes hap-pens to the righteous as to the wicked, and the reverse, is taken up, and the conclusion agriced as that s taken up, and the conclusion arrived at, that, since there is an overruling Providence whose ways we can-not fathom, nothing remains but to direct the view to a lighteous state of retribution hereafter, applying

## Ecclesisstical Commissioners

wisdom and the fear of God to the satisfying of the spirit. "Thus the true enjoyment of the good things of this life is recommended in connection with and in subservience to the fear of God, whose judgment will hereafter clear up all seeming irregularities, and re-ward the works of men as they deserve."

ECCLESIASTIC, OF ECCLESIASTICAL, ck-klo-se-de'-tik (Gr. ekklesia, the church), denotes something belonging to, or set apart for the church, in opposition to civil or secular, what pertains to the world. There are ecclesiastical things and persons; ecclesiastical law, jurisdiction, history, ceremonies, disciplins, &c. Ecclesiastical persons are those when experiences siastical persons are those whose functions consist in performing the service and maintaining the discipline

of the church.

ECCLESIASTICAL COMMISSIONERS.—In 1835 certain royal commissions were issued, directing certain persons therein named to consider the state of the several dioceses of England and Wales, with reference to the amount of their revenues and the more equal distribution of the episcopal duties; and also the state of the cathedral and collegiate churches, with a view to the suggestion of such improvements as might render them most conducive to the efficiency of the established church; and further, to devise the best mode of providing for the cure of souls, with special reference to the residence of the clergy in their benefices. These commissioners, comprising, among others, the English archishops and bishops and the chief members of the government, recommended various improvements in our ecclesisation system; in consequence of which act 6 & 7 Will. IV. c. 77, was passed, forming certain prelates and laymen of distinction into a body corporate, under the name of "The Ecclesiastical Commissioners for England," and empowering them to mature and submit to the queen in council such plans as might be best adapted to give effect to the recommendations of the commissioners. And it was enacted that such plans, when ratified by order in council, should have the force of law. The Ecclesiastical Commissioners have made numerous alterations in our ecclesiastical system, which have been embodied in orders in council. Among these are the crection of the new sees of Ripon and Manchester, and the union of the sees of Gloucester and Bristol; the augmenta-tion of the revenues of the smaller bishoprice from those of the larger, without prejudice to the rights of existing prelates; the suppression of numerous sizecures; the making better provision for the cure of populous parishes; and such like. The corporation, as originally constituted, consisted of thirteen members; of whom five were episcopal, viz., the two arch-bishops and the bishop of London ex officio, and two cosnops and the dishop of London exception, and two other bishops nominated by the crown; five exception members of the government; and three laymen, to be also appointed by the crown. In 1340 the constitution of the board was materially altered, and, besides the two archibishops and the five members of the government. ment, the corporation was made to include all the bishops of England and Wales, three deans, and six common law, equity, and ecclesiastical judges; together with eight permanent lay commissioners, six of whom are in the appointment of the grown and two in that of the archbishop of Canterbury. In 1850, by 13 & 14 Vict. c. 94, authority was given to appoint another board; viz., that of "The Church Estates Commis-sioners," consisting of these months to the sioners," consisting of three members to form the acting committee of the board, and to whom all matters acting committee of the board, and to whom all matters relative to the sale, purchase, management of lands, &c., are intrusted, and who are the responsible officers of the commission. The first and second of these commissioners are lay members of the church, appointed by her majesty by letters patent, during pleasure, the other being appointed by the archieshop of Canterbury. Five commissioners, two of whom must be Church Estates Commissioners, form a quorum of the general board; and in cases where the seal has to be affixed, two of the five must be members of the episcopal bench. The Church Estates Commissioners constitute, either The Church Estates Commissioners constitute, either per se or in combination with two other members of Ecclesiastical Commissioners appointed under seal annually by the board; a committee called "The Estates Committee." There are thus three boards, before one or other of which, according to the nature of the case, all matters must be brought for decision; vis., the

## **Ecclesisatical Corporations**

general board, the Estates Committee, and the Church Estates Commissioners. By 19 & 20 Viot. c. 55, all the duties, powers, and authorities of the Church-building Commissioners are transferred to the Ecclesiastical Commissioners. By 13 & 14 Viot. c. 94, the commissioners are required to lay an annual report before the secretary of state, to be by him submitted to parliament, of all their proceedings for the current year.

ECCLESIASTICAL COMPONATIONS are corporations the

ECCLESIASTICAL COMPOSATIONS are corporations the members of which are spiritual persons. They are either aggregate or sole; in the former case being composed of a number of persons, as the dean and chapter of a cathedral; in the latter, consisting only of one; as a bishop, rector, or vicar. By the law of England every holder of an ecclesiastical benefice is regarded as a corporation, the temporalities of which fall to his successors and do not descend to his breirs.

ECCLEMATICAL COURTS are courts in which the archbishops and bishops adjudicate upon matters pertaining to religion and the clergy. Although we have evidence that the higher orders of the olergy assisted in the national councils in the administration of jusin the national councils in the summission of the tice under the Saxon and Danish kings, yet it is clear that no separate ecclesiastical courts existed anterior to the Norman conquest. William I. gave forth a charter, whereby it was enacted that no lay tribunal should take cognizance of matters affecting the clergy or the church, and that no bishop should take cognior the church, and that no bishop should take cogni-sance of secular matters. According to Coke, these tribunsis judged and determined causes ecclesistical and spiritual; namely, blasphemy, apostasy from Christianity, heresies, schisms, rights of matrimony, divorces, reparation of churches, probate of testa-ments, &c. By an act of parliament which came into operation in January, 1958, the jurisdiction relating to the granting or revoking of wills and letters of admi-vitation was transferred to the Court of Probatenistration was transferred to the Court of Probate and by the act 20 & 21 Vict. c. 85, which created a total change in the law of divorce of England, the exclusive jurisdiction relative to matters matrimonial was transferred from the ecclesiastical courts to the Court formed from the ecclesisatical courts to the Court for Divorce and Matrimonial Causes. (See Divorce Court.) The total number of ecclesiastical courts in England and Wales is 372. (See Court of Peculiars, Consistory Court, Architecon's Court, and Court of Delegates, under art. Courts, and Abelies, Court of See also CONVOCATION.)

Ecclesiastical Law. (See Canon Law.)
Ecclesiastical Year. (See Year.)
Ecclesiasticus, or the Wisdom of Jesus the Son OF SIRSCH, ck-kle-ze-de-tik-us, is the name of an apo-cryphal book of the Old Testament, said to have been originally written in Syro-Chaldaic, by Jesus the son of Srach, a learned Jew; but the exact time in which he lived is uncertain. The book was translated into Greek, with an introduction by his grandson, probably about B.c. 130. It is destitute of any systematic arrangement, and consists chiefly of meditations and proverby relating to religion and the general conduct of life. Its general tone, however, is ethical rather than religious, in some measure resembling the book of Proverbs; and hence some have been bling the book of Proverbs; and hence some have been led to attribute it to Solomon. The sentiments are sometimes so profound and the style so highly poetical, that, according to Addison, "it would be regarded by our modern wits as one of the most shining tracts of morality that are extant, if it appeared under the name of Confucius or of any celebrated Greeian philosopher."

Excussions: "Excussions: "Acklessendlenie (Gr. ekklesia, the

ECCLESIOLOTZ, ek-kle-ze-oll-o-je (Gr. ekklesia, the church, and logos, a word or discourse), a term that is applied to the study of ecclesiastical architecture and ornament, as well as of the vestments and ceremonies belonging to the Anglo-Catholic church. It is s belonging to the Anglo-Catholic church. It is a branch of archeology. A journal is published monthly for the premotion of the science, named the Eccle-siologist, and there is an Ecclesiological Society, based on that which was formerly known as the Cambridge Camden Society. The leading manufacturers of church furniture and ecclesiastical decorations are Messrs. Cox & Son, of Southampton Street, Strand, who exhibited some beautiful specimens of fonts, lecturns, chandeliers, carved oak communion-tables, and stained glass windows, in the Industrial Exhibition of 1862.—Ref. Handbook of Enylish Ecolestology. Echo

ECURLON, eth'-lon(g) (Fr. échells, a ladder).—Bodies of treops are said to be formed in echelon when the front of each body is in a line parallel to the frents of the remainder, but the body itself occupies a position either to the rear of that which is immediately on its right, and in advance of that on its left, or vice versa, according as the movement which follows the formation is to be to the right or left. Each body has its front clear of that which is in advance of it, so that the whole can of that which is in advance of it, so that the woole can be brought into the same alignment by marching forward. It is used in attack and retreat, and especially by cavalry in charging the enemy's troops. It is also an easy and expeditions method of changing the front of a regiment drawn up in line and bringing it into a new position that is in an oblique direction to that which it has just quitted. The most simple illustration of this formation is the zigzag outline presented by a flight of stairs or steps; whence it derives its name.

ECHIDNA, or PORCUTINE ANT-RATER, e-kid'-nd (Gr.)

KOHIDNA, OF FORCUTHA ANT-RATER, c-k-at-ma (Gr., (Eckidma hystrix, Cuvier).—Of this family there are two species,—Eckidma hystrix, peculiar to New South Wales, and Eckidma setosa, chiefly found in Van Diemen's Land. They are of the same size, and, in general appearance, resemble the common hedgehop. They affect hilly countries, living in burrows, and feeding on insects, principally ants and termites, which they capture by the protrusion of their long viscous tongues; which latter organ, as in the case of the true ant-eaters, by an arrangement of longitudinal and annular muscles, is capable of being extended and contracted to a considerable extent. The head of the echidna is small; muzzle much elongated, and terminating in a little mouth, which is destitute of teeth, but furnished with several rows of small spines on the but furnished with several rows of small spines on the pulate, directed backwards. The logs are short and strong, and the feet all fornished with five toes, armed with powerful claws. With the aid of these latter, it can burrow with great rapidity, and when pursued, and not allowed sufficient time to bore a complete hiding in the earth, it enters itself so far as to expose only its prickly back to the threatened assault,

ECHINOCACIUS, c. ki-no-kāk'-tus (Gr. echinos, hedge-

ECHNOCACTUS, c-ki-no-kik'-tus (Gr. cchinos, hedge-hog; cactus, a spiny plant), in Bot., a gen. of plants belonging to the nat. ord. Cactacea. The stem in early globular, and is furrowed with longitudinal grooves, varying in number and depth. The flowers appear on the salient angles of the stem, in the centre of little tufts of bristles and spines. Many species of this genus are in cultivation as stove or greenhouse plants.

ECHINODERMATA, e-ki-no-der'-mai-ts (Gr. echinos, spine, and derma, skin), a chase of radiate animals, the highest in organization of that great division. They are characterized by possessing a well-organized skin, under which, or attached to it, are frequently found plates of solid matter constituting a kind of skeleton. They have a digestive and a vascular system, and a circular nervous system has been desystem, and a circular nervous system has been desystem, and a circular nervous system has been de-tected in many of the species. A muscular system is constantly present. The nutritive apparatus of the Echinodermata is very simple, presenting in most of the family a single oridice, destitute of teeth, in the centre of the lower surface of the body, performing the functions both of the mouth and anus; but in some presenting a digestive cavity, with an orifice for the evacuation of its contents, distinct from that by which the food is taken in. The muscular motion is generally present in these animals, but the organs of motion in them are various, the principal ones being the membranous tubes, which can be protruded at will through the ambulacral apertures, and which have been termed the feet. Whether or no the highest among the Echinodermata possess sight is not a settled matter. Among those who believe that they do, may be named Professors Ehrenberg and Forbes, and among those of a contrary opinion, Professor Rymer Jones. They are all marine animals, and are fairly represented by the star-fish, sea-urchin, and sea-cucumber.

ECHINUS, sk-i'-nus, in Arch, a mondding, sometimes called the ovolo or egg-shaped moulding. It consists of a series of oval hosses in a vertical position, projecting from the face of the moulding, and sometimes separated by a line, terminating in a triangular head, libra a horal semantic.

like a broad arrow. ECHO, ek'-o (Gr. echo, sound), a popular term applied to reflected sound. When sound from any origin

### Eclectics

is propagated through the elastic medium of the atmosphere, undulations, or waves, are produced in the air. When these waves come in contact with a the air. When these wares come in contact with a cliff, or wall, or other opposing surface, they are reflected like light or heat! When the sound is so reflected as to come back to the observer's ear, it is called an echo. In order that the echo may be heard at the place where the sound originated, it is necessary that the reflecting surface should be at right angles to a line drawn to the point where the observer stands. An obligan well though 50 the other or that it can be An oblique wall throws off the ceho so that it can be heard by others but not by the originator of the sound. The most perfect echoes come from surfaces that are either even or so curved as to be in the form of a concave mirror. This, however, is not necessary; for a very distinct echo is often returned from the edge of a wood. Sound travels at the rate of 1,125 feet in a second; consequently it is necessary, in order to obtain an echo, to be at least sixty-two feet from the reflectan early to be a teasy stay two teach from the feature ing surface, and it of a second must be allowed to elapse in order to distinguish the sound from the echo. When nearer than this distance, the echo blends with the original sound, thus making both indistinct. In many churches and public halls, where the principles of acoustics have not been considered, the multitudinous echoes drown the speaker's voice. distribution of sound in public buildings, so that the echoes may assist in strengthening the original sound, is a subject of great importance. An ingenious elergyman at Cambridge invented a parabolic reflector, which had the effect of stunning him while he preached, however impartially the subject of his discourse was imparted to his congregation. When several objects reflect sound, the number of echoes is multiplied, the sounds growing weaker and weaker till they die away. sounds growing weater and weater the they dreaway. In order to produce many sounds, the reflecting plane must be at a considerable distance. At Woodstock there is an echo which repeats about twenty syllables, and the Swiss mountaineers sing their sougs, and especially the Ranz des Vaches, in such a manner that the echo forms an accompaniment to the air. number of syllables that an echo will repeat depends of course on the distance of the reflecting surface from the origin of the sound. At the tomb of Metella, in the origin of the sound. At the tomb of Metella, in the Campagna, near Rome, there is an echo, which, according to Gassendi, is able to repeat an hexameter line requiring 2½ seconds to utter it. The Echoes of Killarney are celebrated, and also those of some of the Welsh lakes. Near Milan, there is an echo which repeats the report of a pistol sixty times.

ECLECTICS, ek-lek-tikk (Gr. eklep, I choose or sections are the control of the pistol sixty times.

is a name given to such philosophers as, without attaching themselves to any particular system, or forming one of their own, professed to select from the various existing systems what they believe to be true, and thus to construct a new and complete whole. The name originated with the Alexandrian philosophers, or name originated with the Alexandrian philosophers, or Neo-Platonists, who professed to gather and unite into one body whatever was true in all the systems of philosophy. The chief representatives of this school are Plotinus, Porphyry, Iamblichus, Proclus, and Clemens Alexandrinus. Modern celecticism is considered to have taken its rise in the 17th century with Bacon and Des Cartes, but it has recently received a fresh impetus themselve the laboure of the Genran philosopher Placel. through the labours of the German philosopher Hegel. In the present day the most eminent supporter of this system is Victor Cousin.

RCLIPSE, e-klips' (Gr. ekleipsis), in Astron., the entire or partial obscuration of a heavenly body; which may be caused in two ways,—either by another body passing between it and the sun from which it derives its light, as in the case of an eclipse of the moon, when the earth passes between the sun and moon, or by the passage of a body between that which is eclipsed and the earth, as in an eclipse of the sun, when the moon passes between the sun and the earth. The eclipses which happen most commonly from the first-named cause are those of the moon (see Luxan Ecursus), the partial eclipse of Jupiter by the passage of one of its satellites between it and the sun, and the eclipses of the satellites of that planet (see JUPITER); while those which are occasioned by the second cause are eclipses of the sun by the moon pass-

## Ecole Polytechnique

occultation of a fixed star by the moon. (See MERCURY. occulation of a fixed star by the moon. (See MINGURY, MOON, VRUES.) Eclipses of Jupiter and his satellites can also happen through the second cause as well as through the first. Eclipses of the sun and moon, like the appearance of comets, were generally regarded by the ancients as omens of some terrible public calamity that was about to happen; and although the theory of eclipses is said to have been known to the theory of eclipses is said to have been known to the Chinese about 150 B.c., yet to this day the lower orders in China imagine that these phenomena are caused by the attempts of a dragon to devour the sun or moon, and they assemble with drums and other instruments, believing that the noise they make has the effect of alarming the dragon, and preventing him from making his anticipated meal. The first scippe that is placed on record is one of the most observed at Matvice on record is one of the moon, observed at Babylon 721 B.C. Thales showed the true cause of lunar eclipses 721 B.C. Thates snowed the true cause of make copiese before 800 B.C.; but Calippus was the first who calculated their revolutions, about 275 years later. Among the most remarkable eclipses of the sun that are recorded in history, may be mentioned that which happened at the crucifixion of our Saviour, and those in 1191 and 1715, when the darkness was so great that the birds went to roost, and flowers closed their petals as at nightfall, and the stars shone brightly at midday. The theory of eclipses and the various phenomena that attend them are given in the articles to which reference has been made above, and all technical terms used in the description of an eclipse will be found under their proper headings. (See EMERSION, IMMERSION, PENUMBRA.)

ECLIPTIC, c-klip'-tik, in Astron., the great circle in which the sun appears to move; so called because the moon is always found to be in or near this circle at the time of an eclipse. The plane of the ecliptic has a mean inclination of 23° 50° to that of the equator. The angle of inclination varies to the extent of 5" or 6" in ten years. It is computed that the obliquity of the ecliptic varies between two extreme limits; namely, from 23° 53′ to 22° 54′, and that it takes about 8,500 years to effect the transition from one limit to another. The change in the angle of inclination arises from the attraction that Jupiter, Mars, and the other planets exercise on the earth. The inclination of the ecliptic exercise on the earth. The inclination of the ecliptic to the equator is said to have been first measured by Eratosthenes about 250 B.c. The ecliptic is divided into four quadrants or area of 200 each by the equince-Into four quadrants or area or area by the entimers tial points and solstices. (See Equinoxis, Solstices.)

These quadrants are subdivided into three area of 30° each, which are called the signs of the zodiac (see Signs of THE EQUIAC), and named from the constellations which happened to be found in each when the distribute of the goldinian of the constellations of the goldinian of the constellations. division ci the ecliptic was first made. These do not now coincide, although the names are still preserved. Astronomical calculations are made from that point of intersection of the equator and the ecliptic, which is the position of the sun in the heavens on March 21st, and which is known as the first point of Aries. (Sec ARTES.)

ECLOGUE, ek-log! (Gr. ektoge, a selection), denotes literally a selection of pieces out of various works, or a collection of the choice pieces of an author; but, from being a name given to the pastoral poems of Virgil, it has since come to be generally applied to that species of poetry. Some imagine the name ecloque to have been originally applied to such poems as were written in imitation of others, and that the ecloques of Virgil were so called as being imitations of the ldyls of Theoritus. The ecloques of Virgil are of various descriptions, only some of them having the true characteristics. racter of pastorals; others contain occasional poems on public and private events of the day, but slightly enveloped in the pastoral costume. The terms ecloque and idyl, in their primary signification, denote the same thing; but custom has made a difference between them, and appropriated the name of ecloque to pieces wherein shepherds are introduced speaking, and idyl to those written in a simple natural style, like the cologue, but without any shepherds in them.

ECOLE POLYTECHNIQUE, al' kole pol-e-tek -neek (Fr. école, school; Gr. polus, many, techne, an art), a military school established in Paris in 1798, under the name of Ecole Centrale de Travaux Publics, or central ing between it and the earth-see Solar Ecuiss, or the joing by Venus or Mercury crossing the sun's disc, or the joung men for the profession of arms and civil engi-

# Economy, Political

M. Lamblardie, director of the Ponts et Chaussées, which are under the control and superintendence of the government in France, and carried out by him with the aid of many eminent Frenchmen of that day. In the course of the following year a more extended course of military study was adopted. The pupils were distinguished by a uniform, and the name of the establishment was changed to the more comprehensive title of Ecole Polystenique, which it still bears, with the addition of the word Impériale, added in 1852. It has been frequently closed on account of the active part that the pupils have taken in the revolutions and has been frequenty closed on account of the active part that the pupils have taken in the revolutions and ementes that have happened in Paris since the com-mencement of the present century; but it has always been reopened as soon as order has been restored. Civilians are admitted between the ages of 16 and 20; but soldiers who have served two years in the army are eligible until 25. Pupils have to pass an examination in order to obtain admission. The course of study ex-tends over two years, when those who can pass the final examination are admitted into the engineers, artillery, civil engineers, or any employment of a similar nature under government.

ECONOMY, POLITICAL. (See POLITICAL ECONOMY.)

ECONOMY, ai-kor'-shai (Fr. écorcher, to skin or flay, from Lat. corium, a hide, or cortex, bark), the name given to a figure used by artists in the study of anatomy, in which the muscles are exposed to view by the removal of the outer skin. In parts of the figure the upper muscles are also removed, to exhibit those that he nearer the bone. These figures are made for the use of artists in plaster or papier maché. There are

also series of drawings which serve the same purpose, and in which the muscles of the human frame are represented from every point of view.

Restast, eks'-tä-se (tr. ekstasis, a standing out, change, or transposition), is a condition of mind in which the soul seems as if it were transported out of the body. The varieties of ecstasy are infinite, but they are all marked by an altered or diminished consciousness. The individual may be either completely passive or violently moved, and may or may not have any knowledge of what is going on around him. Sometimes he assumes the air of inspiration. This mental condition may be induced by fixing the mind too exclusively on one idea or object, so as to overlook all other sensations, as in meamorism and cortain forms of disease. It is also known in connection with certain highly religious states of mind. Among many Eastern nations this condition is cultivated as a part of their religion; and even among Christians there have been writers—as Bonaventurs, Gerson, and others—who have recommended those contemplations which may lead to costasy. People, however, are too apt to mis take the visions of a heated imagination for a higher

take the visions of a heated unagination for a higher and nearer view of spiritual things.

ECSTATICI, eks-tat'-e-si (Gr. ekstatikoi, from existemi, I am entranced), in Ant., were diviners who were cast into trances or cestasies, in which they lay as if dead, but who, on recovering their senses, gave strange revelations as to what they had seen and heard.

ECTOZOA, ek-to-zo'-d (Gr. ektos, without; zoos, living), a term applied to those parasitic animals, such as lice, ticks. &c., which live upon the external parts of other

ticks, &c., which live upon the external parts of other animals. The word is used in contradistinction to animals. The word is used in contrausement animals. Those entomostracous crustaceans which are entozou. Those entomostracous crustaceans which are parasitic upon fishes belong to the ectozos. It is a matter of dispute whether these parasites are the cause of disease, or whether they are the result of previous disease.

EDDA, ed'-dä, a term applied to several Scandinavian songs, supposed to have been collected and arranged by Semund Siguason, surnamed Frodi, an Icelandic priest, who was born between 1054 and 1057, and died in 1133. These songs were first discovered and brought to light in 1424 by Harniel Sandson history of States. in 1133. These songs were first discovered and brought to light in 1643, by Brynjolf Svendson, bishop of Skalbolt, who gave them the name of Edda, or 'grand-mother.' There are, however, two works which bear the title,—the "Edda Sæmundar hins Froda," or the Edda of Sæmund the Wise, and "Snorri Sturleson's Edda." Of these two eddas, the Sørmer is the most ancient, the date of its production being usually attributed to a period between the 6th and 8th centuries. Edda." Of these two eddas, the former is the most ancient, the date of its production being usually attributed to a period between the 6th and 6th centuries. The edda of Sæmund the Wise was published entire at With regard to the incisors, however, there is an ex-

## Edentata

Stockholm, in 1818, in 8vo. A complete edition of this edda was also published by Professor Munch, at Christianis, in 1847, and another in 1859, by Möbins. In 1851 a German edition of both eddas was produced by Simrook. Under the title of "Dreizehn Lieder in der Ursprache, mit einer doppelten Uebersetzung, &c.," the brothers Grimm have translated a part of Sæmund's adda. Snorri Sturleson's adda is a prose composition. edda. Snorri Sturieson's edda is a prose composition, and treats especially of Scandinavian mythology, and also of the language and literature of the ancient Scalds. In the first, or poetical edds, the detached poems attempt to shadow forth a religious system. Many of the poems have evidently been written before the in-troduction of Christianity; but the collection was pro-bably made after the Christian era. The belief in the destruction of the world is apparently derived from Christian sources; and in the very beginning of the edda the germs of one all-destroying catastrophe are presented, which involves not only the destruction of the universe, but also holds out the promise of a resurrection and a happier existence in an abode of bliss. The elder edda consists of thirty-seven poems of various degrees of poetical merit, all relating to Scandinavian mythology. The later edds is divided into two books,—"Gylfaginning," or the Fascination of Gylfa, a story similar to that of "Varthrudnismal," in the elder edds. edds. The second part of the later edds is called "Bragarsedhur," or the Discourse of Bragi, borrowed from the "Oegiradrocks," or the Drinking-feast of Oegir. In this part, Bragi, the Scald of the Gods, discourses upon the origin of poetry. (See SCANDINAVIAN MENTOCORY)

MYTHOLOGY.)

EDDY, ed'-de (Ang.-Sax.), a circular motion of the water, either in rivers or in the sea, but most frequently in the former. Eddies exist between the proper and the counter currents: they are caused by the edges of the one brushing against the other, or by a current running violently against a rock or an elevated shore, and in its recoil meeting some other object of impediment to its course; thus producing a circular motion of the water; the latter kind are often called whirlpools (which see).

Endwinder and are often caned windows (which see, Endwinder and a lighthouse in the English Channel, raised on a dangerous group of rocks that lie to the S.S.W. of Plymouth, and about 14 miles from the Breakwater, in lat. 50° 10′ 54′ N., and lon. 4° 15′ 53′ W. The lighthouse stands on the west side of the group. The Eddystone rocks were found so dangerous to homeward-bound vessels making for Plymouth harbour, that, in 1696, the Trinity Board resolved to erect a beacon on them. Mr. Winstanley, a gentleman of Essex and an ingenious mechanic, undertock the task, and in 1700 he had completed his building, a wooden structure on a stone base, and polygonal in form, which was swept from the rock in a terrific storm, Nov. 27, 1703, while the architect himself was there superintending some repairs. The next was commenced by Mr. Rudyard, a silk mercer, in 1706, and finished in 1709. It was circular in form, and, like Mr. Winstanley's, made of wood on a stone base, but 8 feet lower than his in height, being 92 feet in all. It stood uninjured by the weather until 1755, when it was destroyed by fire. In 1757 Mr. Smeaton commenced the present lighthouse, the base of which is formed of solid block of granite, dovetailed and clamped by irons to the rocks below and to each other; a solid bed of masonry is thus raised 13 feet above the highest point of the rock; here a passage is dertook the task, and in 1700 he had completed his above the highest point of the rock; here a passage is formed communicating with a circular stone staircase, which affords access to the lowest of the four chambers that are formed in the upper part of the building; the that are formed in the upper part of the building; the whole is surmounted by a lantern 24 feet in height, surrounded by a gallery. The tower is circular, being about 27 feet in diameter at highwater mark, and diminishing to 15 feet at the summit. It is 85 feet in height, including the lantern. Mr. Smeaton is said to have derived the idea of its form from that of the trunk of an oak-tree. The upper part was originally made of wood, but it was burnt in 1770, and reconstructed of stone in 1774. The light is fixed, and may be seen shining over the waters at the distance of thirsteen or fourteen miles. teen or fourteen miles.

## Edinburgh University

ception to the rule in the case of the armadillo (Daspus setosus), in which a single tooth is found in each intermaxillary bone, but placed so completely at the sides of these bones, that the front of the mouth is quite destitute of teeth. Chrier observes, that, "alquite destruite of teeth. Onvier observes, that, "although brought together by a purely negative character, the edentata have, nevertheless, some positive mutual relations, particularly in the great claws which encompass the ends of their toes, and which more or less approximate to the nature of hoofs; also in a certain slowness, or want of neithy deviceds slowness, or want of agility, deviously arising from the peculiar organization of their limbs." The number of existing edentata is not nearly so great nor so gigantic in size as at a remote period of the world's history, as the remains of these gigantic herbivora, the

mylodon, megatherium, and the megalony testify.

EDICT, e'-dikt (Lat. edice, I proclaim or publish), is something that is given forth, or proclaimed, by comsomething that is given forth, or proclaimed, by com-petent authority, as a rule of action, more particularly an order, or ordinance, issued by a prince to his sub-jects, to serve as alaw. Strictly speaking, or in this latter sense, edicts cannot exist in Britain, as the enacting of law is not lodged in the king, but in the parliament. In ancient Rome, the ordinances of the magistrates, but particularly of the two prætors, were called edicts. From the uncertainty of the law at that early neriod, it was the custom of the prætors. called edicts. From the uncertainty of the law at that early period, it was the custom of the prætors, on their necession to office, to publish edicts, or rules, for regulating the practice of their courts, and the governors of the provinces had the same authority in their districts as the prætors in the city. The edicts of a preceding prætor were not binding upon his successor, unless he confirmed them; in which case they were styled edict: vetera, or tralatitie, in contradistinction to those issued by himself, which were called edicta nowa. By the Cornelian law (n.c. 56), the prætor of the year was compelled to adhere to the spirit tor of the year was compelled to adhere to the spirit tor of the year was compelled to adhere to the spirit and letter of his first proclamation. In the reign of Hadrian, the practor Salvius Julianus, an eminent lawyer, made a digest of the bost of the practorial edicts from the earliest times, which was ratified by the emperor and senate, and ordained to be always considered as law. By this edictum perpetuum, or perpetual edict, the standard of civil jurisprudence was at length fixed. From that time the power of making edicits was taken from the magistrates, and was at length fixed. From that there have now to making edicits was taken from the magistrates, and vested in the emperors. The celebrated edict of Milan was issued by the emperor Constantine after the conquest of Italy (A.D. 313), and granted to the Christians and others full liberty in the exercise of their religious duties. The edict of Nantes was issued by Henry IV. of France in 1598, granting religious freedom to his Protestant subjects, but was revoked by Louis XIV in 1685. In France, the term edict (édil) has a very wide signification, being applied to every proclamation of the government, of whatever kind.

Entotal Citation, e-dik'-til, by the law of Scot-

land, is the mode of citing before a civil court, one who has no fixed domicile in the country, and cannot be totad personally,—a foreigner, or one who is abroad. Formerly, in such a case, the citation was published at the market-cross of Edinburgh, and pier and shore of Leith; but by 6 Geo. IV. c. 120, and 13 & 14 Vict. c. 36, this is now done by the delivery of copies of the office of Edinth (Citations in the Delivery between at the office of Edictal Citations in the Register-house, Edinburgh, where they are preserved for three years, and abstracts of them published every fortnight.

EDINBURGE REVIEW. (See REVIEW.)

EDIMETER UNIVERSITY WAS founded in 1583 by royal charter, granted by James VI.; and hence it is styled "Academia Jacobi Regia," "King James's College," and "King's College." The lord provost, magistrates, and town council of Edinburgh, were constituted patrons and governors of the princestry. In trates, and town council of Estato and, we taked patrons and governors of the university. In 1621 an act was passed by the Scottish parliament which ratified to this university, in ample form, all the rights, immunities, and privileges enjoyed by the other universities in the kingdom; and this ratification was removed in the treaty of union between England and Scotland, and in the Act of Security. In the beginning of the 17th century, the business of the university was conducted by a principal, who was also the professor of theology, and four regents, who conducted the youth through the course of study secessary to obtaining a degree in arts. Each regent conducted his students

through the entire course, teaching them in succession logio, ethics, and physics, with the kindred diterary and mathematical studies. In 1642 the chair of Hebrew was instituted, in 1874 that of mathematics, in 1890 that of Greek, and in 1695 that of church history. In 1708 the present professorial arrangement in the faculty of arts was substituted for the previous regent-tutors system. The first professor of medicine was appointed in 1665; and in 1707 the foundation of the faculty of law was laid by the institution of a shair of public law was laid by the institution of a chair of public law was laid by the institution of a casir is pointed law, followed in a few years by chairs of civil and Scotch law. Since that time a number of new chairs have been added to all the faculties. From its founda-tion, in 1582, until 1858, the government of the univer-aity was in the hands of the magistrates and town council of Edinburgh; but it was taken from them by an act of parliament in 1855, and placed in the Senatus Academicus and the University Court, in connection with a general university council. The patronage of those chairs, which had been previously in the gift of the town council, was by the same act transferred to seven curators,—three nominated by the University Court and four by the town council, and hold office for three years. The offices of changellor, vice-chancellor, and rector were also instituted. The chancellor is the official head of the university, is elected by the general council, and holds office for life. The vice-chancellor is nominated by the chancellor, and performs his duties in his absence. The rector is elected by a general poll of the matriculated students of the university. president of the University Court, and holds office for three years. The University Court is composed of the rector, principal, the lord-provest of Edinburgh for the time being, and five assessors, elected respectively by the chancellor, the rector, the town council of Edinburgh, the general council, and the senatus. The rector and his assessor continue in office for three years, the other assessors for four. It constitutes the court of appeal from the Senstus Academicus, and has the power to effect improvements in the internal arrangements of the university, after due consideration with the sens-tus and council, and with the sanction of the chancel-The principal is resident head of the college and president of the senatus. He is appointed by the cura-tors, and holds office for life. The principal and pro-fessors constitute the Senatus Academicus, which is intrusted with the superintendence and regulation of the teaching and discipline of the university, and with the administration of its revenues and property. general council of the university consists of the chancellor, rector, and other members of the University Court, the principal and professors, masters of arts of the university, doctors of medicine of the university who have, as matriculated students, attended classes in any of the facuties for four complete sessions, and all who have established, within three years of the passing of the Universities Act (2nd August, 1858), that they had attended the university as matriculated students and attended the university as matriculated students for four essions, or three sessions and afourth in some other Scottish university. The number of members of the general council at present (1871) is 2,255. They meet twice a year, in April and October, to take into consideration all questions affecting the well-being and prosperity of the university, their decisions being represented to the University Court who executed that University Court who executed the transmitter Court when the transmitter Court who executed the transmitter Court when the transmitter Court who executed the transmitter Court when the t sented to the University Court, who are to return a judg-ment thereon. The chairs of the university are comprehended in the four faculties, the affairs of each faculty hended in the four faculties, the affairs of each faculty being superintended by a dean, who is elected by the professors of the faculty. The faculty of arts comprehends the chairs of humanity, Greek, matternaties, logic and metaphysics, moral philosophy, natural philosophy and rhetoric, and English literature; also universal history, practical astronomy, agriculture, music, and Sanskrit; attendance on the first seven of which is required for the degree of master of arts. The faculty of theology has plained and district the faculty of the control of district the faculty of the degree of master of arts. the degree of master of arts. The faculty of theology has chairs of divinity, Hebrew, eccleaisatical history, and biblical criticism and antiquities. The faculty of law has chairs of public law, civil or Roman law, and conveyancing. The medical faculty comprehends chairs of botany, institutes of medicine, practice of physic, anatomy, chemietry, midwifery, natural history, materia medica, clinical surgery, medical jurispradence, surgery, and general pathology. There are two secons in the year,—the winter seesion, which opens in the beginning of November and ends with April, and

### Edition

the summer session, which opens in the beginning of May and ends with July, the latter being almost entirely confined to the medical classes. The ordisery course of study necessary for the degree of M.A. ex-tends over four winter sessions; and candidates for that degree must be examined on all the seven subjects of instruction embraced in the above course of study; of instruction subreced in the above course or succey; and the examinations way be conducted partly in writing and partly vied voce. Students who have passed satisfactorily the examinations for M.A. may, before taking the degree, offer themselves for a further examination, with a view to graduation with homours. There are four departments for honours; viz., classical literature, mental philosophy, mathematics, and natural science, in any one or more of which students may present themselves for examination. Each student has to pay unusually a matriculation fee of £1. 1s.; and the fees for each class per session vary from £2. 2s. to £4. 4s. A fee of £3. 3s. is payable for the examinations for M.A. There are three medical degrees conferred for M.A. There are three medical degrees conterred by the university; viz., bachelor of medicine (M.B.), master in surgery (C.M.), and dector of medicine (M.D.). No one is admitted to the degree of M.B. or C.M. who has not been engaged in medical and surgical studies for four years, one of which must be at the university of Edinburgh. He must produce certificates of having attended certain classes, and the medical and surgical practice of a general hospital; and he is also subjected to examination, both in writing and vird wae, on the various branches of study. The degree of M.D. may be conferred on any candidate who has obtained the degree of M.B. and is of the age of 24, provided he has been engaged for at least two years in attendance on an hospital, or in practice. The degrees of D.D. and LL.D. are honorary distinctions. The professors of humanity, Greek, mathematics, natural philosophy, chemistry, and music, have each an assistaut, the first four having salaries of £100 each, the last two of £200 each. Conjoined with the professors as examiners for degrees, are three examiners in arts and three in medicine. The total number of scholarships and bursaries connected with the university is 112, and the annual value is about £1,800. They are mostly for the faculties of arts and theology, are generally of small amount, and in the patronage of the senstus, The total town council, or of private individuals. The total numbers of students in the winter session of 1861-62 was 1,427; being in arts 618, medicine 516, law 202, theology 01. The university library contains about 130,000 printed volumes, and above 700 MSS., many of which are of great interest and value. It originated in a bequest of about 300 volumes in 1580, and was subsequently largely augmented by donations from various persons; among others by the celebrated Drummond of Hawthornden, who bequesthed his library to it. It was formerly entitled to a copy of every book entered in Stationers' Hall, in lieu of which privilege it now receives a sum of £575 per annum. The museum of natural history was catablished in 1812, —a great part of it having been collected by the exer-tions of the late Professor Jameson. It receives a government grant of £200 per annum. The anatomical museum was founded in 1800 by Dr. Monro Secundus, who presented his own anatomical collection and that of his father to the university, for the purpose of "demonstrating to the students the structure, physiciogy, and diseases of the human body." The Royal Botanic Garden in connection with the university was founded in 1670, and extends to seventeen acres, having an extensive range of greenhouses and hothouses, with a large palm-house. There are also several private

## Education

sterectyped, and to print copies as may be required from the sterectype plates. In a bibliographical point of view, some editions of books are much more valuable than others. Generally speaking, the last edition of an author's work is the best, as containing his latest improvements; but in some cases circumstances give a provements; but in some cases circumstances give as greater value to earlier editions, or sometimes the first. Sometimes a book acquires its chief value from the editor, or even from the publisher; as Bentley's Horace, or the Aldine Classics. (See BIBLIOGRAFILY, BOOK-TRADE.)

EDITOR, ed-it-or (Lat. edo, I publish), is one who edits or prepares for publication the writings of another. We may distinguish two classes of editors:—1. those whose object is merely to reproduce the works of another in their purity, and content themselves with adding notes or commentaries to the text; and 2. those who have the general superintendence of some large literary work, encyclopædia, magazine, newspaper, or the like, receiving contributions from various persons, which they may have to correct, cut down, supplement, or reject, according to their character and the ment, or reject, according to their character and the general plan of the work. In the former case the editor requires to be a man of great learning, taste, judgment, and exactness, and to have a full appreciation of his author, having to judge critically of the various readings, to explain the obscure passages, supply omissions and references, and generally to present his author in the most pure and favourable light to the noble. It at he latter case the qualifications require to public. In the latter case the qualifications require to be of a much more general and varied kind. Here a full and comprehensive view of the whole work is required, as well as an acquaintance with all its minor details, and the bearings of each upon the whole. Generally, a minute and accurate knowledge is necessary on a vast variety of subjects, and a readiness and full command over them, so as at once to be able to

bring them to bear upon any particular point.

Education, ed-u-kai-shun (in Lat. educatio is derived from the verb educo, I lead, or bring our or forth). The Latins used the word not only in relation to man, but also to the lower animals, and even to plants. To but also to the lower animals, and even to plants. To educate was to cultivate or bring out their various properties. With us, the term is properly confined to the human species, as being alone capable of education in any high or proper sense of the word. Man, says Kant (Veber Erziehing), is the only creature capable of cducation. The lower animals require, at most, only nourishment and protection to enable them to reach their proper condition, and to perform all the functions of their nature; but man is possessed of powers and faculties indefinitely perfectible, and which require to be trained and directed by others; otherwise they may be useless, if not absolutely injurious. In this way has Providence wisely provided for the progress of the human race. While the lower animals of to-day are not a whit more advanced than animals of to-day are not a whit more advanced than when they were originally created, man has been gradually progressing towards a higher and more per-fect state of development, and that exactly in propertion as the true principles of his nature were understood and acted upon. Each generation profits by the learning and experience of those that preceded it, and in like manner transmits its knowledge to its successors. Education, in its most extended sense, then, has to do with the progress of the human race towards a more perfect state of development. It marks its gradual advancement from the earliest dawn of history to the present time, observing the various circumstances that may have tended to promote or retard its an extensive range of greenhouses and hothouses, with a large palm-house. There are also several private museums or collections in connection with some of the classes.—Ref. Edinburgh Viviversity Calendur, 1871.

Enimon, edinh'un (Lat. edo, I give out or publish), is the number of copies of a work that are printed at one time before the types are again taken down by the may constitute an edition are hence very various, depending in a great measure tipon the sale which is expected to have a large or continued sale, to get it stances that may have tended to promote or retard its progress, and seeks to gather from the whole instruction for the present, and seeks to gather from the whole instruction for the present, and seeks to gather from the whole instruction for the present, and seeks to gather from the whole instruction for the present, and seeks to gather from the whole instruction for the present, and seeks to gather from the whole instruction for the present, and seeks to gather from the whole instruction for the present, and seeks to gather from the whole instruction for the present, and seeks to gather from the whole instruction for the present, and seeks to gather from the whole instruction for the present, and seeks to gather from the whole instruction for the present, and seeks to gather from the whole instruction for the present, and seeks to gather from the whole instruction for the present, and seeks to gather from the whole instruction for the present, and seeks to gather from the whole instruction for the present, and seeks to gather from the whole instruction for the present, and seeks to gather from the whole instruction for the present in present.

It is a present man as an individual destined for a future and higher state of existence, for which lise the preparatory training. In this sense a man is educated, either for good or evil, by everything which he may respect the whole instruction for the present and bigher state of existence, from the oradle to the grave. In a still active for good or

the training which he then receives marks his character through life. While we shall be obliged, in the present article, to confine our attention to the last of these, as embracing the most important period of life these, as emurating the most important period of me as regards education; yet it is only by keeping in view that our entire life here is but a preparation for another and a higher state of existence, and that all our training must be directed to that object, that we can arrive at clear and correct notions respecting it. Education, then, we would define to be the full and harmonious development of all the powers and capacities of man,—full, that is, each to the highest point of which it is capable; and harmonious, each in complete unison with all the rest. In other words, it is the bringing of his entire nature into the highest is the bringing of his entire nature into the highest state of perfection of which it is susceptible; for, in the words of Milton, the end of education is "to repair the ruins of our first parents,"—to re-store harmony and beauty and power to that sys-tem which was ruined by the Fall. It is a common error to confound education with instruction, and much misunderstanding is the consequence. can be indeed no education without some instruction, but there may be a great amount of instruction with very little education. The best educated man is not he that knows most, but he that can do most. Bacon has well said that men are apt to set too high a value upon their acquirements and to underrate their faculties. It is impossible, from the nature of the present work, that we can traverse the vast field that the subject of education opens up to us, or notice the numerous important questions that are connected with it; and perhaps we shall best employ our space by noticing some of the more important points which are as yet but little understood or acted upon. In order to educate a human being, it is first of all necessary to know something of the nature of that being; for education can be right or true only in proportion as it is based upon a knowledge of that nature, and of the laws to which it is subject. Until a knowledge of human nature is more generally diffused and acted upon, we have little hope for any great progress in education. Man is not only subject to certain laws regulating his growth and determining his condition, but he is also possessed of a variety of faculties, differ-ing greatly in their nature and character, having different periods of development, and requiring different modes of treatment. It is only by extending our knowledge of these, that we can expect to arrive at a true system of education, which has for its object their full and harmonious development. The true educator carefully observes the workings of Nature, and pursues the course that she indicates, aiding her in her opera-tions, and, it may be, occasionally gently bending her to his ends, but never directly opposing or thwarting her, for he knows that she ever worketh wisely and well. Man, then, is possessed of a twofold nature,—a spiritual and a material; the one partaking of the nature of spirit, the other subject to the laws of matter. "The soul is that side of our nature which is in relation with the Infinite." "By this immortal soul," says Dr. Carpenter, in his Human Physiology, "man is connected with that higher order of being in which Intelligence exists, unrestrained in its exercise by the imperfections of that corporeal mechanism through which it here operates." It is unnecessary for our present purpose to attempt to speculate as to the nature of either spiritor matter apart and by itself. In man we have to do with the two in inseparable connection; and it is only with man that education connection; and it is only win man that caucation con-cerns itself. But not only are the two inseparably connected, but there is every reason to believe them to be inseparably present in every act. Physiologists, indeed, tell us, that as every movement of any part of the body causes destruction to a portion of the tissues of that part, so, in like manner, every thought that passes through the mind causes destruction to a por-

tendency of science in the present day is to break up tendency of science in an experience and partial man into pieces, viewing him as distinct and separate parts, instead of one beautiful and united whole. We believe that not only are spirit and matter inseparably connected in man, but that the former is everywhere limited by the latter; that the body is, in fact, the prison-house of the soul. Not only is there every reason to believe this to be the case from what is generally regarded as the nature of spirit, but we cannot nerally regarded as the state of spars, but we same otherwise account for the pari passu growth of the mind with the body,—its feebleness in childhood, its strength in manhood, and its decay in old age. Our rational soul, says Hippocrates, is always the same throughout the whole course of our life,—in youth and in age, when we are children and grown men; but the body, on the contrary, never continues in one state, but is constantly changing. It is only by bearing in mind the intimate connection that subsists between body and spirit, and the dependence of the latter upon the former for its manifestations, that we are able to explain many of the mental phenomena; and hence, too, we in many cases obtain a clue how to proceed in edu-cation. We thus come to know that the body and spirit in man are not two distinct and opposing elements, the one being improved and strengthened as the other is weakened and depressed. The two are indissolubly united,—the spirit giving life to the body, the body giving direction and form to the mind. And not only so, but our physical nature plays a much more important part in the animal economy than is generally believed or acted upon in education. The brain, which is the organ of the mind, is a part of our physical constitution, subject to physical laws, to disease and decay, requiring exercise to develop it, and a due supply of arterial blood to maintain it in a state of health. To the educator, too, it is important to know that he is not in the performance of his to know that he is not, in the performance of his duties, dealing with incomprehensible spirit moving in another sphere, and the laws of whose operations it is impossible for him to divine; but that the spirit is strictly limited, and subject to the laws of matter; that it is in obedience to these laws that its operations are carried on, and that, however mysterious some of are carried on, and that, however mysterious some or its workings may seem to be, they are all the result of causes which he ought to strive to find out. We see further here a valuable provision for the gradual improvement of the human race. It is well known that mental as well as physical quali-ties are transmitted from parents to children, however inexplicable the laws by which it is regulated may be at present, or how many apparent exceptions may occur. In our view, the general fact is explained by the physical character of the mind's organ; that, as the outward physical form is transmitted from parents to children, so is the physical character of the brain; and the man who has fought the good fight against his avil affections and lusts, and has kept the faith with his better nature, not only enjoys the fruits thereof himself, but may have the satisfaction of knowing that he may thereby be transmitting to his posterity the most valuable of all inheritances. "In order," says Sir B. Brodie, "to make the most of the intellectual powers, the animal system should be maintained in a state as nearly as possible approaching perfect health." "The state of mind, whether as regards the moral or the intellectual, is, to a very great extent, subjected to the influence of physical canees." But not only does this show the primary importance of physical health in education, but it leads ance of physical health in education, but it leads us to look for the like laws governing the mind as we know to govern the body. The great law in education, mental or physical, is exercise. If we want to develop a muscle, we exercise it; if we want to improve a faculty, we must, in like manner, exercise it. In the one case, as in the other, the exercise must be proportioned to the strength of the individual, and every period of exercise about the autocaded by a time every period of exercise should be succeeded by a time passes through the mind causes destruction to a portion of the nerve-matter of the brain. Thus every period of exercise should be succeeded by a time of rest. It is now the generally received opinion thought of the mind partakes of the material as well as the spiritual; as well as the material. This is of importance to bear in mind; for we constantly hear people speaking of mental acts and physical acts, as if the two were distinct and separate, and not intimately sonnected the one with the offer. In fact, the whole of rest. It is now the generally received opinion among philosophers and men of science, that different faculties of the mind have different portions of the brain for their organs; and hence it is that the mind, when tired of one subject, can turn with fresh vigour to another, in the tame way as one tired with walking may sit down to some manual occupation. We would, however continue the warren of practice the content of t

## Education

from one kind of violent or protracted exercise to rom one kind of violent or protracted exercise to another; more particularly from severe mental to great physical exertion, or vice verad. The exercise of any part of the body causes an increased flow of nutritious blood to that part; and this continues for some time after the exercise has ceased, to supply the waste that has taken place; and hence to withdraw the blood at once in another direction by exercising other organs of the body, interferes with the regular course of nature. the body, interferes with the regular course of nature, and deprives the wasted part of its due nourishment. But while the two elements of man's nature are concerned in every act, some partake more of the one and others of the other; and hence we have the common division of them into physical and mental acts the former comprising the outward acts. tal acts, the former comprising the outward acts of the body, the latter mental thought and feeling; according to which we have a twofold division of education, into physical and mental. Of physical education, which deals with the proper development of the physical powers, it will not be necessary to say much. It is, indeed, a subject of the utmost importance, and entitled to much more attention than it has yet received, as it is not only upon it that the health of the body mainly depends, but it is by it that the hody is made the ready, willing, and obedient servant of the mind. Its object ought to be to impart strength, dignity, and grace to every movement of the body. The value of correct habits formed in early life, whether there were be useful secondlished as graceful. ther they may be useful accomplishments, a graceful deportment, correctness of pronunciation, or any kind of manual dexterity, continues to be felt throughout the course of one's life. As a means of physical education, course or one sine. As a means or paysical education, Ling's, or the Swedish, system of gynnastics is much superior to any other. It is not only founded on strictly physiological principles, but the attention of the pupil is excited and kept alive by his constantly iving direction from the teacher as to the different movements that he is to perform; and thus it is in some measure a mental as well as a physical exercise. It is also free from that violent exercion that characterizes the other systems of gymnastics. Mental education has to do with the mind of man, and ought to be based upon a knowledge of that portion of his nature. The mind is that which feels, thinks, and acts, or is characterized by feeling, thought, and action. The first of these comprises not only those feelings and impressions that are communicated through the senses, but also the emotions and moral feelings, and generally all such as arise from states of the mind itself. In thought, the mind turns itself in upon those feelings, reasons of them, judges of them, arranges and compare them. In the last of these we have the active printhem. In the last of these we have the active prin-ciples of the mind, or those that propel it into action; as the desires and the will. There are two kinds of actions; either passing outwards through the body, or inwards, directing the thoughts, calling up ideas, and forming conceptions. Here again we would caution against the error of regarding the mind as consisting against the error of regarding the mind as consisting of distinct and independent faculties, and not as one entire and united whole. "All our intellectual processes so completely interpenetrate each other, that it is impossible to separate them into distinct faculties and assign provinces to each."—(Morell's Psychology.) Feeling, thought, and action, therefore, are only different manifestations of the same active principle, and ought properly to go together. One of the great errors of the present assembles. In they are kept too much ought properly to go together. One of the great errors of the present systems is, that they are kept too much apart. Feelings are not so cultivated as to improve thought; and thought too frequently terminates in itself, without going out into action. The proper object of all thought and feeling is action, which is the great end of life. "A rigorous separation of the speculative from the practical," says Professor Fraser, the successor of Sir W. Hamilton in the chair of philosophy in Edinburgh, "is apt, by causing a disruption of the complex nature of man. . . to occasion weakness and vacillation in the conduct of life." Men fail not on much from not knowing what is right, as from so much from not knowing what is right, as from not acting up to their knowledge.—(See especially on this subject Foster's admirable essay on Decision of

## Education

the moment than after mature consideration; not from acting blindly, but from following a truer guide than reason. But to explain this will lead to another important question connected with the phenomens of mind,—that is, to what extent are we conscious of the operations of the mind? This is a question that has not hitherto received much attention in this country. not interest received much attention in this country. The doctrine of unconscious perception, or latent thought, originated with Leibnitz, and from him has passed into the principal philosophical systems of modern Germany. It has received various names; as, latent or ultra-conscious thought, unconscious cerebration, reflex action of the brain, &c. This doctrine may be illustrated in many ways. A man, after puzzling over a difficult problem for a long time, and, unable to solve it, turns his attention to something else, and after a time, on returning to it again, he finds it all arranged and plain before him, although he is quite unconscious of having once thought of it in the interval. Certain conditions of the atmosphere produce lightness or depression of spirits, by means of impressions of which we are insensible; and the unpleasant dreams which result from indigestion are to be attributed to the same cause. We know, too, that beyond consciousness, there exist in the mind systems of knowledge of which there exist in the minu systems of anomaly states, and which are only revealed on extraordinary occasions; as delirium, madness, somnambulism, &c., Within this as delirium, madness, somnambulism, &c. Within this unexplored region exist the instincts and intuitions of our nature,—those innate principles of morality and beauty which seem to us so incomprehensible, guided and directed, it may be, by feelings of pleasure and pain. "There is a latent intelligence within us which pain. "There is a latent intelligence within us which works teleologically, apart from will, feeling, sensation, or any kind of consciousness whatever."—(Morell.) "I do not hesitate to maintain," says Sir William Hamilton, "that what we are conscious of is constructed out of what we are not conscious of; that our whole knowledge is in fact made up of the unknown and incognizable." It seems as if the mind might be compared to a dark cavern, into which consciousness, like a light at the mouth, cermits us only to look a like a light at the mouth, permits us only to look a little way. In the dark and unknown region beyond are stored up all our knowledge and all our experience; and here are carried on those wonderful mental pro-cesses which are only known to us by their results. The highest and most perfect of the mental operations are instinctive or unconscious. Genius in its higher forms is of this kind, being moved and guided by inner im-pulses little accountable to reason. Genius had sponpulses little accountable to reason. Genius had spontaneously produced great works before rules of criticism could be laid down; and her greatest works still are but little indebted to such helps. "What," says Göthe, in speaking of his works, "is in such cases termed invention, was with me spontaneous" ("Ich habe nie über das Denken gedacht"). "Wobserve with confidence," says Carlyle, "that the truly strong mind, view it as intellect, as morality, or under any other aspect, is nowise the mind acquainted with its strength; that here, as before, the sign of health is unconsciousness." "Here (underneath the region of consciousness, in its quiet mysterious depths, dwells what vital force is in us;—here, if aught is to be created, and not merely manufactured and communicated, must the work go on. Manufacture is intelligible, but trivial; creation on. Manufacture is intelligible, but trivial; creation is great, and cannot be understood." And this is true is great, and cannot be understood. And this is cute of the moral as well as the intellectual powers, the highest morality being also instinctive; for, as he says, "had we never sinued, we should have had no conscience." Policemen are necessary where rogues exist; but, were society perfect, there would be no rogues, and no need for policemen. Further, not only are the highest acts of the mind instinctive, but the tendency of all mental acts is to become so by practice. Acts of which the mind was at first painfully conscious, become gradually less so, until at length they may be performed quite unconsciously. Were calucators to perceive and act upon the principle that there is in human nature something above and Character.) One great means of imparting decision of the Character to children is to teach them unquestioningly and unhesitatingly to obey. Further, we believe that and unhesitatingly to obey. Further, we believe that earliest period of life that our instincts are most active if people were true to their feelings, they would generate and most success,—more especially as it is during the earliest period of life that our instincts are most active if people were true to their feelings, they would generate and most succeptible of improvement. Everything rally be found to act much more wisely on the spur of that there is in human nature something above and beyond reason, their labours would be crowned with more success,—more especially as it is during the earliest period of life that our instincts are most active and most susceptible of improvement. Everything

primary instincts of the child. If we observe nature, we shall find that early shildwood is pre-eminently the we shall that ward park and the speciments the time for imbibing knowledge. Who can estimate the amount of knowledge that a child acquires during the first few years of its life,—without effort, without anything but by the apoutaneous workings of its own mind? This knowledge, however, workings of its own mind? This knowledge, however, is entirely objective, being acquired from nature and life around it. This, then, is the period for perceptive teaching,—for storing the mind with objective knowledge. But during this time the child is not content with being merely the recipient of knowledge: true to its instincts, it soon begins to reproduce what it has acquired,—to imitate what it sees and hears, and to express what it feels. The power of seizing wird ideas of things—of complaints associating, and connecting of things,—of combining, associating, and connecting them with the appropriate words or signs, is now in the highest state of intensity. Nature, therefore, shows that in education "our principal aim at this time of life should be to furnish nutriment for the growth and expansion of the powers of inward reprerowth and expansion of the powers of instance of the sensition; that is, for strengthening the memory, training and regulating the imagination, giving full play to the laws of association, and producing the capacity of expressing ideas in clear, luminous, correct, and copious language. All these habits of mind can generally be acquired with great facility at this time of life, but if a control of life. of life; but, if neglected som, so difficult does the process of their education afterwards become, that it is a thousand chances to one whether they will ever be acquired to any degree of perfection at all."—(Morell.) As the reasoning faculties become more advanced and mature, these powers gradually degenerate. It is, therefore, of the greatest importance, not only that they be improved to the utmost during this period of life, but that nothing should be done to abridge it by prematurely developing the reasoning faculties. fortunately, however, this is the tendency of much of the teaching of the present day. The teacher, not content with receiving a correct answer to a question, must also have the reason why it is so. The less the child has to do with giving or receiving reasons at this time the better. Direct teaching is the best, and rules, or the application of them, should be as little resorted to as possible. Still more reprehensible is the practice of presenting to the child's mind both the right and the wrong at the same time; or, after receiving a correct answer, asking if he is sure it is not something else. It not only tends to loosen its hold in the child's mind, but to make him doubtful of his knowledge. "Spoil not," says Dr. Andrew Fuller, "thy memory "Spoil not," says Dr. Andrew Fuller, "thy memory by suspecting it. How canst thou find that true which thon wilt not trust." As in morals, the greatest injury you can do an innocent child is to suspect him; so in you can do an indocent could be to suspect mm; so in teaching, you cannot do a greater injury to a scholur than to make him suspect his knowledge. In questioning a boy, so as to bring out his knowledge, care ought to be taken to fellow only the natural order. If questioned on the subject of his reading, the questions should follow the order in which it was read and not taken at follow the order in which it was read, and not taken at random throughout the lesson, or, as is sometimes done, by proceeding from the end to the beginning. This is of more importance than it may at first seem; for there are certain laws of the mind, commonly known as the laws of association, according to which things are stored up in the memory and reproduced. One of these is, that things are reproduced in the order and with the associations that they were received, and an habitual departure from this order is destructive of one of the finest and most important laws of mind. It is in this way that one comes to acquire the style and an tas way that one comes to acquire the style and modes of thought of another, the thoughts flowing naturally in the same way, the ideas suggesting each other in the like order. In every process of thought or course of reasoning there is a certain natural order in which the ideas suggest and follow each other; and any interference with this order tends to introduce confusion, whoughts springing up that are not directly wanted, and the mind becoming erowded with irrelevant matters. As it may mechanical operation, the work goes on best when the materials are brought to hand as and in the order that they are required; so mand as and in the order that they are required; so in mental operations, the mind as the best when the thoughts and words are brought before it exactly in the order finit they are needed,—

when it is given them at the proper time what they shall say; and if people would give more beed to the instinctive portion of their nature, they would find that its workings were much more true and reliable than any resulting from reason. Reason is but to be regarded as supplementary to that higher portion of our nature,—intuition. In the words of an old philosophical nature,—intuition. In the words of an one participants divine, whose works are by no means so well known as they deserve, "Intuition is by far the must perfect and excellent way of knowledge." "Our intuition here, however, is so short-sighted, that if we knew no more than we can thus attain to, we should not have sight enough the words are in our increase through the word; so that our we can thus attain to, we should not have sight enough to direct us in our journey through the world; so that our feeble eye is assisted with the glass of reason,—natu-rally, indeed, a very good prospective, but which logic, and especially algebra, has improved into a telescope. Still its but an artificial way of seeing, and all art sup-poses and argues a defect in nature;" but "hereafter said especially an artificial way of seeing, and an artificial way of seeing, and argues a defect in nature;" but "hereafter we shall be so far from needing any logic to direct us in our reasoning, that we shall have but little need or use even of reason itself,"—(Norris's Reason and Fuith.) But reason is given to us, and is necessary for us here, and therefore requires cultivation. Though not the But reason is given to us, and is necessary for us here, and therefore requires cultivation. Though not the highest faculty of our nature, it is the most practical, and that which has the closest bearing upon the occupations and duties of life. It is defined by J. D. Morell to be "the co-ordinating power in relation to all our other intellectual processes,—as that which gives unity and solidarity to them, siding us at once in the pursuit of truth, and in adapting our lives to the state of things in which we exist."—(Psychology.) This faculty deals with the ceneral and the abstract; separates our deals with the general and the abstract; separates our knowledge into definite parts; arranges, classifies, and embodies it in accurate terms; expands it into formal propositions, and draws conclusions from one proposition to another. As the mental powers become some-what mature, then the main portion of our intellectual education should be directed to the regulation and development of this faculty by means of the higher branches of study,—logic, mathematics, science, and philosophy. We have said little of the means of eduphilosophy. We have said little of the meass of education, of what is to be taught, and the order in which it ought to be communicated; but this is the less necessary, as those who shall have intelligently followed us in the above remarks will be able in some measure to judge for themselves on these points. The great thing in each case is to follow Nature, pursuing the course that she points out; and, as a general rule, the order of the progress of the race is the order that ought to be followed in the education of the individual members of it. We may mention that Dr. Neil Arust has, in his Survey of Humos Progress, given a sketch of the various branches of knowledge in relation to the state of the s education In fine, then, the object of education is the full and harmonious development of all our faculties; the bringing our entire nature, physical, moral, and intellectual, into the highest state of perfection of which it is capable. Who can tell how high that is? So far as our present knowledge or experience goes, it So far as our present knowledge or experience goes, is indefinitely perfectible. However much we may see the physical, moral, and intellectual parts of man apart now, they are each and all necessary, in their respective spheres, to constitute a perfect man, whom we believe to be a thing of beauty, physically, morally, and intellectually. God has not in vain inmorally, and intellectually. God has not in vain instilled principles of beauty into the mind of man; and according to a fine expression of Kant's, which, however, is but an adaptation of one of the sublimest docever, is but an acaptation of one of the sublinest doc-trines of the Platonic philosophy,—that of ideas, there is in every man's mind the ideal of a perfect man. Beauty and goodness always go together; the one produces the other. A man's character is generally impressed upon his countenance; and hence there was truth, as well as wit, in Sidney Smith's remark of a man having all the ten commandments written on his forehead The culture of the moral feelings gives a benignant and loveable expression to the countenance; intellec-tuality stamps itself principally upon the forehead; while the general admiration which a fine figure and while the general admiration which a fine figure and manly bearing naturally excite, show that physical education must also play an important part in the forming of our perfect man. (See NATIONAL EDUCATION, SCHOOLS, SCHOOL BOLEDS, UNIVERSITIES.)
EDUCATION, MILITARY.—This term may be equally applied to the education given to candidates for com-

## Education, Technical

missions in the army, as well as to officers who have already served, or to the system adopted by govern-ment to afford instruction to soldiers and their children. Instruction in all the subjects most necessary for an officer to become acquainted with, combined for an officer to become acquainted with, combined with strict military discipline, is given to cadets or youths from 16 to 19 years of age at entrance, at the Cadets' College, Sandhurst; the Royal India Military College, Addiscombe; and the Royal Military Academy, Woolwich. (Sec Cadet, Military; Military Academy, Woolwich. (Sec Cadet, Military; Military Schools.) A college was also exablished at Richmond, known as Cavalry College, in 1867, under private control, to afford a fitting education to youths about to actes that branch of the service. Officers are about to enter that branch of the service. Officers are able to render themselves eligible for staff appointable to reader themselves slightle for stati appointments at Sandburst under recent regulations. (See STAFF COLLEGE.) The sons of deceased soldiers are brought up and educated at the Royal Military Asylum, Chelsea, better known as the Duke of York's School, as many being admitted annually, by selection, as the vacancies that occur and the resources of the establishvacuations allow. On leaving, they either enter the army or are apprenticed to learn some trade. For the improvement of the soldier, schoolmasters are attached to each regiment, and stationed at the various camps and depôts; and instruction is regularly given in the elementary branches of knowledge to such as desire it, combined with lectures on various scientific subjects. (See REGIMENTAL SCHOOLS.)

EDUCATION, TECHNICAL. (Sec TECHNICAL EDU-CATION.)

EDULORATION, e-dul-ko-rai'-shun (Fr. tdulcorer, to sweeten, purify).—In Chem., edulcoration is the work-ing of precipitates after filtration, to free them from any excess of precipitant or supernatant fluid. It is generally performed by means of a bottle containing two tubes, one drawn to a fine point and reaching to the bottom of the bottle, the other only entering the cork a few inches. By blowing down the latter tube, the water is forced out of the former in a fine stream.

BES, set (Sax. al), a fam. of fishes (Anguilla), belonging to the apodal section of the Malacopterygii. Their long and cylindrical bodies are covered by a thick and soft skin, in which the scales are so deeply imbedded as to be scarcely apparent. The gill orifices are very small, and are situated far back; so that there is a long eassage from the gill-chamber outwards; and hence passage from the ginemanner outside, see the the gills not soon becoming dry, these fishes can remain a long time out of the water, some of them, indeed, leaving it of their own accord. Most of the cels are included in the Linnman genus Murana, and are divided by some naturalists into the families Symbranchivided. de, Muranida, Anguillida, Congerida, and Ophicurida. The Synbranchida have the gill-passages so united under a common integument as to present externally only a single orifice: they are almost destitute of fins. The species are few, and they are chiefly found in tropical seas. The Muranida are also generally destitate of fins, or nearly so: they are all destitute of scales, and never found in fresh water. The Anguillida are fresh-water fishes, though some of them occasionally visit the sea. They have pretty large pectoral fine, anal and dorsal fine extending to and encompassing the tip of the tail, and numerous longish scales embedded in groups in the skin, so as to resemble latticework. Ophiswide, or snake-cels, are distinguished by the tail ending in a conical pointless fin. At least three species of cels are found in this country,—the Sharp-nosed, the Broad-nosed, and the Snig. The first-The firstmentioned, which is common in streams and lakes, is distinguished, as its name implies, by its comparatively long and narrow muzzle. Its colours are dark olive-green on the upper surface of the head and body; under surface silvery white. The clearer the stream in which the eel lives, the more vivid are its colours. The broadnosed cel is not uncommon, and is often found in the same waters with the sharp-nosed, from which, however, it is to be readily distinguished by the comparaever, it is to be readily distinguished by the compara-tively greater breadth of its head and the situation of its eyes, which are placed in advance of the angle of the mouth; the body, moreover, is thicker in propor-tion to its length, and the teeth more numerous and stronger; and the dersal and spal fins, which are much deeper and thicker, commence farther back. In some parts of England this sort is known as the grig-eel.

## Efforescence

The snig is in many respects intermediate between the hroad-nosed and sharp-nosed species: its colour is closely like that of the sharp-nosed cel. "In the compa-rative breadth of the nose," says Mr. Yarrell, "the snig is intermediate in reference to the broad and sharpnosed eets, but rather more resembles that with the nosed eas, but rather more resembles that with the sharp nose. It has a slight but elongated depression extending from the enterior edge of the upper jaw to the upper and back part of the head; the tubalar openings of the nostrils are longer, and the nucous pores about the lips larger and more conspicuous; both jaws rounded at their extremities, the lower one the longest; teeth longer and stronger than in the common sharpnosed species; gape large; the angle and the posterior edge of the eye on the same vertical line; the pectoral edge of the eye on the same vertical line; the pectoral fins, the commencement of the dorsal fin, and the vent, are each placed nearer the head than in either of our fresh-water eela." The snig is considered superior to other kinds for the table; but the sharped-nosed cel other kinds for the table; but the sharped-unsed eel attains the greatest size,—sometimes five-and-twenty, and even thirty pounds weight. The eel migrates at the approach of winter to warm estnaries, generally brackish, and at times perfectly salt. Those, however, which live in ponds, and cannot emigrate, bore down into the mud, and there remain during the colder months of the year. They are sometimes dup out of the mud, land to give a sometimes dup out of the mud, land to give a sometimes dup out of the mud-banks of rivers and lakes in considerable quantities. Mr. Yarrell mentions that the London market is supplied with eels by Dutch fishermen, from Holland. There are two companies in Holland, having five vessels each. Each ship is built with a capacious well, in which large quantities of cels are stored till they are wanted. Each vessel carries a cargo of this fish, weighing from fifteen to twenty thousand pounds, the duty on which cargo is £15.

the duty on whom cargo is 2.15.

Rel, Conger. (See Conger Erl.)

Erl, Electrical. (See Electrical Erl.)

Refrect, cf-felt (Int. effecre, to produce), in Paint.
and Sculp., a term used to express the impression that
correct drawing and judicious and harmonious coluring in a picture, or the outline and position of the figure or figures in a well-executed piece of sculpture, is apt to produce on the mind of the spectator. When is apt to produce on the mind of the spectator. we are looking at a work of art, and nothing incongru-ous or distorted in outline or design, or offensive to the eye in colouring, meets the view, we are prone to express our satisfaction with that at which we are look-

express our satisfaction with that at which were sooning by saying that the effect is very good or pleasing.

EFFECT, the impression produced on the ear and
the mind by the performance of good music. It is the
joint result of composition and performance; and is
the chief object of both the composer and the executant, on whose ability and skill it entirely depends.

EFFENDI, 'ef-fen'-de, among the Turks, a title of honour given to civil dignituries and others, in contradistinction to the title aga, which is only bestowed upon courtiers and military officials. The word is equivalent to the English sir, or the French monsieur.
Thus the minister of foreign affairs is called Refserfiendi; the first physician of the sultan is termed Hakim-effondi; the priest of the seraglio, Imameffendi, &c.

EFFERVESORUE, of fer-ves'-ens (Lat. effervesco, I boil over), in Chem., the escape of gas in musute bub-bles from a liquid. Thus, when any strong amaonis is uncorked, effervescence takes place, from the relief of pressure. It also happens when a gas is replaced in a solution by some liquid or solid, as where sulphuric acid is added to a solution of carbonate of sods to

acid is added to a solution of carbonate of soda to unite with the alkali, acting free the carbonic acid.

Effice, of feje (Lat. effigies, a likeness, from fueger, to make or form), the resemblance or likeness of any person executed in metal, stone, wood, plaster, &c., or depicted in a drawing or painting. Although it is generally taken to mean a likeness in any form or material, it is a word but seldem, if ever, used in the meterial, it is a word but seldem, if ever, used in the fine arts. It may be better applied to the rude representation of any one, such as those of Guy Fawkes, which were formerly carried about the streets on November 5, than to any portrait, bust, or statue.

Bepronscance, of fiother case (Lat. effloresce, I blossom).—In Chem., efflorescence is the formation of an opaque powder upon the surface of a crystal, from its losing its water of crystallization spontaneously, the action generally consinuing until the whole has fallen to

powder. Familiar instances take place in common carbonate of soda and sulphate of soda, or Glauber's sait. It is the reverse of deliquescences. Expressors, of further than (Lat. of two). from effundo, I pour out or forth), denotes generally the pouring out of any liquid, and is applied, in Med. to the scose of any fluid out of a vessel or viscus naturally containing it, and its lodgment in another cavity in the cellular substance, or in the substance of parts. It also some-times signifies an oosing or morbid secretion of a fluid from vessels that have not been ruptured; thus surgeons often speak of coagulable lymph being effused

on different surfaces.

E FLAT, the note E depressed half a tone,—the minor seventh of F, and the second flat introduced in modulating by fourths from the natural diatonic

scale mode.

EGG, eg (Sax. eg, Lat. ovum), a body produced in the females of birds and certain other animals, containing an embryo or fectus of the same species, or the substance from which a similar saimal is ultimately produced. Those animals in which reproduction takes place by means of eggs are called oviparous. The marsupial quadrupeds and the mono-tremata form the connecting link between the warm-blooded animals which are oviparous and the truly viriparous animals, which only belong to the mammalia. The number of eggs produced varies greatly in different animals; some birds only produce one egg in a year, while others produce as many as twenty. The roe of some fishes conbirds only produce one egg in a year, while others produce as many as twenty. The roe of some fishes contains myriads of eggs. The eggs deposited by some animals are enveloped in a gelatinous substance; others are connected in various ways, sometimes being in the form of a string. The eggs of a large number of birds are used as articles of food, those most generally used belonging to the class of birds called poultry. The common domestic fowl, the turkey, and the peahen, are birds whose eggs are most generally used all over the world. In some of the islands of Beetland. the eggs of several species of sea-birds, such as the gull and guillemot, form an important article of food gui and guillemot, form an important article of food among the inhabitants. Although the eggs of birds are principally eaten, the eggs of the turtle are also considered a luxury; and the eggs of fresh-water tor-toises are valuable for the oil which they yield. An ordinary hen's egg has an average weight of 875 grains, of which the shell and its inner membrapous coating weigh 37 grains; the albumen, or white, 529's grains; and the yolk 251'8 grains. The shell contains about two per cent. of animal matter, and one per cent. of the phosphates of lime and magnesia, the rest consisting of carbonate of lime, with a trace of carbonate of magnesis. (See Albumen.)

of magnesis. (See ALBUMEN.)

EGG-BPLES. (See SOLANUM.)

EGG-BIED (Hydrochelidon fuliginosum, or Sterna fuliginosu), a bird of the Gull fam, sometimes called the sooty tern. It is somewhat larger than the other members of the tern family, and has a long and sharp the south of the tern family, and has a long and sharp than the converged and algular wines. bill, nearly straight, compressed, and slender; wings narrow, long, and pointed; tail deeply forked; colour glossy black on the upper parts, edges of wings, fore-head, and under parts white. It abounds in the West-Indian seas, and is chiefly valuable for its eggs, which are about two inches long, cream-colour, sparingly streaked with purple. So highly are these eggs esteemed, that their gathering is quite a considerable trade. The nest of the egg-bird is made in the sand, and the eggs number from one to three.

and the eggs number from one to three.

Egg-Taple.—The trade in eggs forms no inconsiderable branch of our commercial intercourse with France, as the English poultry are not able to supply the home demand. Vast quantities of eggs are, howthe home demand. Vast quantities of eggs are, however, brought from the country to London and other ever, brought from the country to London and other largetowns. The importation of eggs from France gives employment to a large number of small vessels. In 1854 mentions a large number of small vessels. In 1854 mentions on a base that contracts in size as it appears to a large number of small vessels. In 1854 mentions on a base that contracts in size as it appears to a large number of small vessels. In 1854 mentions on a base that contracts in size as it approaches the floor of the building, instead of expanding from the substance of the sum of the shaft, as is usually the case. The capitals are sometimes bell-shaped and adorned with lotus-leaves, while others are square in form, with a human face sculptured on each from Beigium. The value of these eggs has been computed at £336,000. The imported eggs are seldom equal in quality to those

produced at home. The duty formerly paid on imported eggs is now removed.

ported eggs is now removed.

Reg-hatching. (Soe Hatching.)

EGYPTIAN ARCHITECTURE, e-fip'-shim.—The architecture of Egypt is the oldest in the world, and is superior to that of any other country, Assayris along excepted, in its colossal proportions, massive structure, general magnificence, and grandeur of conception. It has the merit of being entirely original, and possesses peculiar characteristics that distinguish it in a striking manner from that of any other country. The striking manner from that of any other country. The carliest specimens of Egyptian architecture that yet? carriest specimens of Egyptian architecture that yet remain to us, and which will probably endure as long as the world lasts, are the pyramids, and the monumental records known as obelisks; but to ascertain the efficiency they had attained in this art, we must go to the temples of Karnac, Edfou, Denderah, and that of Abou-Sambul, hewn out of the solid rock, as well as the architectural remains that still exist at Thebes and other ancient cities of Egypt. The pyramids are buildings of great solidity, but of simple form. They are built on a square base, with four triangular sides, that meet in a common apex. They are supposed to be royal mausoleums, and were built between 1500 and 1000 R.C. (See PYRAMIDS.) The obelisks are four-sided shafts of great size, terminating in a pyramidal top. They are hewn out of a solid block of stone; top. They are hewn out of a sond under on soone, they are also elaborately carved with hieroglyphica. The temples cover a great space of ground, and stand in a walled inclosure. Before the temple itself there is a large square court, surrounded on three sides by a colonnade. Access is obtained to this court through a doorway of great height, flanked on either side by quadrilateral towers, diminishing in size as they approach the top. The doorway and side towers are proach the top. The doorway and side towers are adorned with coloseal sculptured figures, and in some cases an avenue of figures, generally sphinxes, was made, leading directly to the doorway we have mentioned. The temple itself was generally raised, the court between it and the grand entrance being composed of a series of broad steps rising in a gradual slope. These steps lead to a magnificent hall or fortico, occupying nearly the entire width of the court. tico, occupying nearly the entire width of the court, in which there are generally six rows of pillars which support the flat and massive roof. From the portice we enter a smaller hall, also divided into narrow spaces by pillars that support the roof, and after crossing two or more chambers, each narrower than the one before it, we gam the innermost chamber, or shrine, exactly fronting the entrance, in which the statue of the di-vinity was placed, to whose worship the temple was dedicated. The area occupied at the temple at Ediou dedicated. The area occupied at the temple at Edfout is 414 feet long by 154 broad, the towers on either side of the gateway being 104 feet long by 47 broad at the base, and 94 feet in length by about 30 in width at the summit; but these proportions, large as they may summt; but these proportions, large as they may appear, are eclipsed by those of the temple of Karnac, the great hall or portice of this magnificent building being 338 feet long by 170 broad, and covering an area nearly equal to that of the entire temple of Kdfou. The entire length of the temple of Karnac is about 1,200 feet, and its breadth about 360. The columns, entablatures, and mouldings, are the great distinctive features of Egyptian architecture, in addition to the marked peculiarity that their doors and windows, and marked peculiarity that their thouse said the seven the buildings themselves, present; namely, the convergence of the sides; so that the breadth at the base is greatly diminished in extent at this summit. The size of the columns is in proportion to the extent of the building in which they are placed. At Karnao they are 9 and 11 feet in diameter. First they were square in form, then polygonal, and at last circular shafts were made. All are elaborately sculptured.

upper part of which projected considerably beyond the face of the walls of the building. The roof was perfectly flat. The doorways are surrounded by a flat moulding, and surmounted by a cornice and lintel of great depth. Figures attached to the walls were generally executed in alto-rilievo, like those that flank the doorways of the Assyrian palaces; but the hieroglyphics and representations of historical events were carved in low relief, in a style peculiar to Egyptian sculpture known as cave-rilievo. (See CARTOUCHE.) carven in low relief, in a style peculiar to Egyptian sculpture known as cano-riliceou. (See CARTOUGHE.)
The walls were adorned with paintings in red, blue, green, black, and yellow, on a white ground : gilding was also introduced as an embellishment, and the sculptured columns and the ecilings were also painted. The domestic dwellings of the Egyptians seem to have been built of brick, consisting of rooms ranged round a central court planted with trees, and having a founa central court planted with trees, and having a foun-tain in the centre. They were sometimes two and three stories high. The flat lintel is common to Egyptian, Grecian, and Assyrian architecture; the method of forming arched doorways and vaulted passages was known to the Egyptians, but it was seldom resorted to by them, and then principally in the construction of combs.

EGYPTIAN BEAN, (See NELUMBIUM.) EMBETIACER, er-e-ti-ai-se-e (in honour of D. G. Ehret, a German botanical draughtsman), in Bot., the Ebretia fam., a nat. ord. of dicotyledonous plants in the sub-class Corolliftora, resembling the Boraginacea in most of their characters, but differing from them in having the carpels completely united, so as to form a two or more celled overy; in their terminal style, and drupaceous fruit. There are 14 genera and 297 species, chiefy tropical trees or shrubs. The properties and uses of these plants are not very remarkable. Some species of Ehretia hear edible fruits. Some have a delicious odour, as Heliotropium peruviunum, the Peruvian heliotrope.

EIDER DOWN, i'-der down (Swed. dun), the down from the breast of the eider duck. The best is that which the birds have stripped from their breasts to provide a lining for their nests; that which is taken from the dead bird being considered inferior in quality, and called dead down, in contradistinction to that which is taken from the nests, and termed live down. The down is chiefly used for making coverlets that take the place of blankets on the continent; the down being placed between two pieces of linen or other material, and the whole quilted together to keep the feathers in place.

EIDER DUCK (Somateria mollissima), a species of wild duck inhabiting the frozen regions of the north. It is very abundant in Iceland, Lapland, Green-land, and Spitzbergen, on the shores of Baffin's Bay, ac. Generally, it is of a size intermediate between the domestic duck and goose. The head is large; the middle of the neck small, with the lower part of it spread out very broad, so as to form a hollow between the shoulders. The bill is horn-colour, the upper manthe snoulders. The one is non-count, are upper mandible being forked in a singular manner towards each eye, and covered with white feathers on the sides as far forwards as the nostrils. The top of the head is soft velvety black, cleft behind by a narrow streak of white; the feathers from the nape of the neck to the while; the feathers iron the nape of the neck to the throat are pulified out, and look as though the ends had seen clipped. The cheeks, chin, upper part of the neck, the back, and leaser wing-coverts, are white; bastard wings and primary quills brown; the front part of the neck to the breast is dun-colour, and thence to the under part of the tail deep black; tail brown; legs short and yellow. In Icoland and Norway the breeding-grounds of eiders are carefully protected, so that as little as possible may interfere with the growth of the eider-down crop. This curious and beautiful down grows on the breast of the bird, and the mode adopted to procure it is somewhat singular. The nest is composed of seaweed, and any hole or ledge is evidently considered an eligible building site. The number of eggs laid is usually five, eix, or seven: they are three inches long, two broad, and of a uniform pale green. When first deposited in the nest, they are allowed to go uncovered; but in few days the mother begins to pluck the down from her breast, and to cover them over; and this process would seem to be indispensable to the growth and latching of the young birds; for, if the nest be plundered, till the female has throat are puffed out, and look as though the ends had

left no more down on her breast, the male bird will begin to furnish the comfortable covering from his own body. The common practice is to remove the whole of body. The common practice is to remove the whole or the eggs with the down, twice, and to leave the third lot of eggs, that the birds may not be thinned in num-ber. The gross weight of the down yielded by one bird in a single season is half a pound; but this, when elsenned, is reduced by one-half. The elasticity of eider-down is so extreme that three-quarters of an ounce will fill a man's hat. It is capable of great compression, so that the down makes its appearance in balls no larger than a breakfast-cup, but weighing about three pounds. The flesh of the eider duck, though not so toothsome as that of the species familiar to us, is fit to be eaten, and is said to become of excellent flavour when the bird is wholly or even partially domesticated. They are evidently capable of easy domestication, at least sons who reside near the sea. The Hon. A. Dillon, who spent a winter in Iceland and Lapland, relates that five of these birds chose as their location the ground under a narrow bench that ran along the windows of his house, and that when approached they evinced no timidity, and would even allow their backs to be stroked.

EIDOGRAPH, V-do-graf (Gr. eidos, form, and gra-phein, to write), a machine which answers the pur-pose of a pantagraph, and is used for copying plans and drawings on the same scale, or for enlarging or reducing them in any proportion that may be desired. It was invented by the late Professor Wallace, of Edinburgh. It consists of a beam which moves in at horizontal plane, sliding in a secket that works on a vertical pin, which enters a tube in a mass of metal beneath it. The ends of the beam are fitted with pulleys that also work freely in an horizontal plane. Pieces watch-spring pass round the pulleys, being fastened to them at one point by a simple pin to prevent them from slipping on the circumference, and connected by wires, so as to form a kind of endless band, which may be tightened or loosened at pleasure by swivel screws. Rods of metal slide in sockets under the pulleys. One of these has a tracing-point and the other a pencil, but at opposite ends of the arms, so that they may be in a line passing diagonally through the central pin, on which the beam, and consequently the whole machine, works. The beam and arms are graduated and may be self to any required scale. When it is desired to use the machine, the operator, after setting the beam and rods as may be desired, passes the tracing-point over the drawing to be copied; a corresponding motion is communicated to the pencil at the opposite end of the other rod, which delineates a fac-simile of the

drawing to be copied.

EISTEDDYON, i-stoth'-vod (Welsh eistedd, to sit),
a name applied generally in Welsh to any meeting or
concourse of people, but more particularly to the
assemblies of the Welsh bards and minstrels, who
anciently formed an hereditary order. These meetings were forbiden by Edward I, at the conquest of Wales, but they were renewed by Henry VII., who was of Welsh origin. They have been again revived during the present century, and eisteddfods are held periodically at various Welsh towns in succession, at which prizes are awarded for proficiency in the Welsh tongue, and for poems in that language, and playing on the harp.

EJECTMENT, e-jekt'-ment (from Lat. e, out, and jactus, cast), is the name of an action at law, by which a party entitled to the immediate posses-sion of lands or other corporeal hereditaments may recover that possession from the party wrongfully withholding it. Until abolished by the Common Law Procedure Act, of 1852, this action exhibited the most remarkable string of fletions then recognized by most remarkable string of fictions then recognized by the courts of common law. This was by an action commonly known as John Doc v. Richard Roc. (See Don, John.) By the Common Law Procedure Act, of 1852, a writ is now issued out of any of the superior courts of common law, in a prescribed form, directed to the person or persons in possession by name, and generally to all persons entitled to defend the posses-sion of the premises therein described, setting forth son of the premises therein described, setting forth that some person or persons, by name, claim to be entitled to the possession, and to eject all other persons; and commanding those to whom it is directed, or

such of them as deny the alleged title, to appear in the court from which the writ is issued, within sixteen days after the service thereof, to defend the possession of the property. This writ (which remains in force for three months) is served by delivering it to the tenant in possession personally, or to some member of his family or household personally, on the premises; and any other person, on filing an affidavit that he or his tenant is in possession, may be allowed to appear in court and defend the action. If no appearance be entered, the claimant obtains an ordinary judgment entered, the chamant obtains an ordinary judgment by default, on which the sheriff gives him possession; but if an appearance be entered, an issue is at once made up without any pleadings, and the question is submitted to a jury.—Ref. Stephen's Commentaries on the Laws of England.

the Laws of England.

ELEMAGNACE, el-e-äg-nai'-se-s (Gr. elaia, an olive, and agnos, chuste), in Bot., the Oleaster fam., a nat. ord. of dicotyledonous plants in the sub-class Monochlamydee. They are trees or shrubs, with ontire exstipulate leaves, usually scurfy. The flowers are mostly discious, rarely perfect. Male flowers amentaceous, bracteated; sepals 2—4, or united; stamens definite, perigynous. Female flowers with an inferior tubular calyx and a fleshy disc; metivation imbricate; overy superior, l-called, with a solitary ascending ovule. Fruit inclosed in the succulous calyx; indebiseent. Seed solitary, ascending, with thin ascending over the memoscal new succession, with thin albumen; embryo straight, with an inferior radicle. There are four genera and thirty species, mostly natives of the northern lemisphere. The fruits of several species of the typical gen. Elaagnus are enten in Persia and some parts of India. Those of an English member of the family, namely Hippohaë rhamnoides, the sea-buckthorn, are also edible, and have been employed in the preparation of sauce for fish; but their use requires caution, as they contain a narcotic principle.

ELECCARPUS, elec-o-kar-pus (Gr. claia, an olive, and karpos, a fruit), in Bot., a gen. of plants belonging to the nat. ord. Tiliacex. The Molucca berries, which are frequently made into necklaces in India, are obtained from the species E. serratus. The outer portion of the fruit is pulpy, but the endocarp is hard, bony, and beautifully furrowed. The pulp is carefully removed from the berries when they are used

ELAIS, el-a'-is (Gr. elaion, oil), in Bot., agen. of palms. The two species E. gaincensis and melanococca are the Guines oil-palms, from the fruits of which the vegetable butter called palm oil is extracted. The fruits are drupaceous, and the oil is found in the sarcocarp. It is of a rich orange-yellow colour, and is extensively used in this country in the manufacture of candles and soap, being the chief raw material worked up at the great factories belonging to Price's Patent Caudle Company. In Africa it is used as food by the natives. Being emollient, it is sometimes used in medicine as an embroca-tion to spasms and bruises. The hard stony putament of the same fruits yields a limpid oil. Palm wine may be prepared from the juice which flows from the wounded spathes of the two palms.

ELAND, e'-land (its name at the Cape) .- This animal, considerably the largest of all the antelopes, is known by soveral different names,—the impoofoo, claud, Cape elk, canna, or bastard cland, are among the many terms applied to it. The ordinary claud is a large heavy animal, weighing, at full growth, from 7 cett. to 9 cett.; and, contrary to the rule amongst antelopes in general, is prone to be fat. Its usual size is that of a full-grown horse, measuring generally a little more than eight feet in length, and standing full five feet at the shoulder. The borns of the male are thick and heavy and about a foot and a half in length. They are considerably the largest of all the antelopes, is known heavy, and about a foot and a half in length. They are straight till they arrive at about three inches from the tips, where they bend outwards. They are also surrounded by a thick spiral wreath, which becomes indistinct at the points. The horns of the female cland are longer and smaller, and the spiral wreath is often absent. both sexes the head is long and pointed, the ears large, the neck thick, and in front of the chest is a loose banging skin or dewlap, with a border of long hair on its margin. A short erect mane of dark brown hair its margin. A short crow many the state of the forstead to the rost of the tail. This mane is directed backwards along the spine, but is reversed on the neck. The tail is more than two tail. This mane is our but is reversed on the neck.
738

feet long, and terminates in a tuft of long black hair. The flesh of the cland is more prized as food than that of any other wild animal of Southern Africa. When of any other wild animal of Southern Africa. When dried and cured, the large muscles of the thighs are looked upon with high estimation, and are usually called thigh-tongues. Elands were formerly very common in the neighbourhood of Cape Town; but they have been so universally hunted, that they are only to be met with in the most retired parts of the The disposition of the cland is very mild and gentle, and it seems predisposed to domesticity. It is gregarious, and lives in large herds upon the low hills and level plains. Elands, when husted, are soon tired, as they are usually fat and short of wind. Very often they drop down during a chase from plethors. Of late years there have been many attempts made to intro-duce the eland among the animals used for food in duce the cland among the animals used for food in England. The attempts have all been successful, and not only in the Zoological Gardens in Regent's Park, but also in the grounds of noblemen and private gentlemen, the cland has been reared and bred. Concerning its flesh as food, Dr. Livingstone, the celebrated Africau traveller, writes as follows:—"Our parly was well supplied with cland-flesh during our passage through the desert; and it being superior to beef, and the animal as large as an ox, it seems strange that it has not yet been introduced into England." The Acclimatization Society has given much attention to the qualities of the cland; and it is more than probable that in a few years it will be largely bred in Great Britain. The scientific name of this animal is Antilope oreas. Antilope oreus.

ELASTICITY, e-lae-tis'-e-te (from Fr. élastique, elastic, primarily from Gr. elastes, an impeller forward), that property which certain bodies possess of recovering their former figure or state after internal pressure, tension, or distortion. Elasticity is perfect when the body exactly recovers its primitive form after the force by which its form has been changed is removed. Perfect elasticity is, however, not to be found in nature. Aëriform fluids or gases approach nearer to perfect elasticity than any other substances. In solid bodies, as a general rule, elasticity is destroyed by use: thus a bow loses its elasticity by being kept bent. by use: thus a bow loses its elasticity by being kept bent. Iron and steel can have their elasticity increased by being tempered, that is, by contracting their volumo suddenly after being expsuded by heat.

ELATERIUM. (See F. GBALIUM.)

FLATINACEM, e-lift -e-nui-se-e (Gr. elate, a fir; the leaves resembling those of the fir-free), in Bot., the

Water-pepper fam, a nat. ord. of dicotyledonous plants in the sub-class Thalamiflore, consisting of six genera and about 22 species,—little annual marsh-plants with hollow stems and opposite leaves, with interpetiolar sti-pules. The flowers are small and axillary; sepals and petals 3-5; the laiter, as well as the stamens, being hypogynous. The fruit is capsular, 3—5-celled; the placentation axile. The styles 3—5; stigmas capitate. The seeds are numerous and exalbuminous. The plants of this small order are scattered all over the model. The concerned to president heard. They are generally considered acrid.

ELBOW, el-bo (Sax. elneboga), in Anat., is the joint of the arm formed by the lower end of the humerus and the upper end of the radius and ulna. The lower end of the humerus is received into the hollow of the ulna, so as to produce a hinge-like arrangement, and the upper end of the radius forms also a small part of the The surface of the humerus in contact with the ulna is limited, internally and externally, by a promineat ridge, and is hollowed out in the centre; that in contact with the radius is a small rounded eminence which moves in the cavity of the latter. front of the humerus, above the articular surface, are two depressions that receive the coronoid process and the head of the radius during flexure, and behind is a large fosse for the reception of the olecranos, or large process of the ulns, in the extension of the forearm. Where the bones touch, their surfaces are covered with cartilage, and their articular ends are kept in place by a number of ligaments.

ELROW-BEERS, the plates of metal used to cover the chow-joint at the junction of the brassart, or rere-brace, and the vaut-brace, the former of which served as a protection to the arm between the shoulder and the clbow, and the latter to the lower part, between

### Elder

the shoulder and the wrist. They were sometimes called conditeres. The elbow-piece is shown in the illustration appended to the article on Brassauts.

BLDER, el'der (fr. prebletere), is the comparative degree of the Ang. Sax. eld, and denotes one who is older than others; and hence an overseer or ruler. In the ancient Jewish polity, the elders were persons of considerable age and experience, and who consequently obtained certain there is almost over other considerables. obtained certain, power and influence over others.
When Moses was sent into Egypt to deliver the children of Israel, he assembled the elders of the people, and told them that God had appeared unto him. Afterwards Moses associated with himself in the government seventy of the elders of Israel, which, according to the generality of interpreters, was the beginning of the Sauhedrim (which see). Every city, also, had its elders, who seem to have possessed a certain local jurisdiction. In the New Testament, the term chiler is employed to designate a certain class of officers in the church, regarding the office and duties of whom there are various conflicting opinions. Whether the elders were lay officers of the church, has long been mutter of dispute. It appears certain, however, that the elders mentioned by St. Paul (1 Tim. v.) did not hold the same office as word and decrine." It is said that Calvin admitted lay elders into church courts on what he conceived to be the sanction of the primitive church, and "as an effectual method of preventing the return of inordinate Presbyterian church, are certain laymen who are elected and ordained for ecclesiastical office, and who, in conjunction with the minister and descons, composa in Scotland the kirk session. The number of elders is proportioned to the extent and population of the parish, and they are usually persons of tried character and Christian excellence. They have no right to teach or to dispense the sacraments; but in every question of jurisdiction within the parish, they form a spiritual court, of which the minister is officially moderator; and in the presbyteries, synods, and treneral Assembly, they sit as representatives of the several sessions or consistories. Formerly the power of the kirk-sessions in Scotland was much greater than at present. They used to take cognizance not only of all grosser immoralities, as swearing, drunkenness, lewdness, absence from public worship, &c., but also card-playing, racing, dancing, and the like. Their duties, in many respects, now correspond to those of churchwardens in the Church of England.

ELDER, in Bot. (See Samucus.) En Dorano, et do-ra'-do (Span., the golden region), the term applied by the Spaniards, in the 16th century, to an imaginary land abounding in gold and all kinds of precious stones, and supposed to be situate in the interior of South America, between the rivers Amazon and Orinoco. The origin of this fable was due to the heated imaginations of the avaricious Castilian adventurers, who loved to dream of regions more golden than those of Mexico and Peru. Many expeditions were fitted out for the purpose of discovering it, and, were fitted out for the purpose of discovering it, and, although each proved abortive, the belief in the existence of the "golden land" survived until the commencement of the 18th century. In England, even, the fable took root, and Sir Walter Raleigh twice visited Guiana in search of "El Dorado." The term has now become the property of the poet, who uses it to express a land of boundless wealth and felicity, like the Paradisc of Mahomet or the Elysian fields of the ancients.—Ref. Edinburgh Review, vol. lxxii., art. Sir Walter Ruleigh

ELEATICS, e-le-lit-iks, the name of an ancient sect of philosophers, so called from Elea, a Greek colony of lower Italy, which was in all probability the residence,

## Election of Members of Parliament

rather a pantheism. They opposed the polytheism of the times by maintaining the infinity and self-existence the times by mantaning the infinity and self-existence of One; but they could not separate that One from the world. The apparent changes of the universe they regarded as mere illusions of sense, the Infinite being without change or corruption. "Whatever estimate," says Ritter, "may be formed of the Electic doctrine and its results, it cannot be denied that, as the first attempt to correct the conceptions and representations of sense by the pure notions of reason, or, at least, to reduce them to their true value, it is in the highest degree deserving the attention of the philosopher. By it the pure speculative element of thought was first abstracted from all that is incidental to its concrete appearance, and consciousness awakened thereby to a truer notion of philosophy. At the same time it is far from unprofitable to observe the course of the attempt to abstract from the sensible appearance, the perfect knowledge of true being, however unsuccessful the casay."

ELECAMPANE. (See INULA.)
ELECTION, e-lek-shun (Lat. electio, a choice, selection), in a general sense, is the act of selecting one or more from a greater number, for any use or purpose. In Law it is also when a man is left to his own free will to take or do one thing or another, which he pleases. It is the obligation imposed upon a party to choose between two or more inconsistent or alternative rights or claims, where he cannot enjoy the benefits of both. In courts of equity the principle of election is frequently applied where a party has inconsistent rights, and is compelled to elect which he will enforce. It has been said that the doctrine constitutes a rule of law as well as in equity, but that, in consequence of the forms of proceeding at law, a party cannot be put to elect. Every act of election presupposes a plurality of gifts or rights, with a right to the party to elect any one of them. Though, as a general rule, a person is not allowed to sue in equity and at law to, the same thing, but is obliged to elect in which court he will proceed, yet there is an exception in the case of a mortgage, who may proceed both in equity and at law at the same time.—Ref. Wharton's Law Lexicon.

Electron, in Theol., "is a purpose of God referring to certain and definite persons of the fallen and sinful

race of mankind, determining to unite them to Christ, and by means of that new connection with him to bring them to perfect holiness and happiness."—(Pye Smith.)
That God hath out of his mere good pleasure from all I that God into out of his mere good pleasure from all eternity predestined some of the human race to everlasting life, and left others to inevitable and eternal damnation, is a doctrine clearly taught in Scripture, and is a necessary consequence of the omniscience and foreknowledge of God. (See PREDESTINATION.)

ELECTION OF MEMBERS OF PARLIAMENT.—When a

new parliament is to be summoned, the lord chancellor receives a written command from the sovereign in council to that effect, and directs the clerk of the erown in chancery to issue writs to the returning officer of each electoral district. The returning officer of each county must, within two days of the receipt of the writ, cause proclamation to be saide of the time and place of said election, which must be not later than the twelfth nor sooner than the sixth day after said proclamation. In boroughs, the officer must proceed with the election within six days after the receipt of the writ, having first given three clear days' notice thereof. On the day fixed for the election, the writ is read in public by the returning officer, and candidates are pro-posed and seconded by qualified electors. A shew of hands is then taken of those present, and the officer declares the apparent result, without, of course, knowing whether those who have held up their hands be electors or not. If the parties are satisfied with this declaration, the election is at an end; but if the parfounder of this sect, and the principal seat of its cultivation; for its great propagators, Parmenides and Zeno, were natives of this town. The Eleatic school is pre-eminently distinguished from the Pythagoroan and Ionian by the recklessuress with which it strove to attain to an exclusive knowledge of the supra-sensible. They attempted to construct a system of the universe, and maintained that the aboutes of all truth was something independent of and source of all truth was something independent of and superior to sense. Their system was a monotheism, or

## **Election Committees**

day following that fixed for the election, unless a Sunday, Good Friday, or Christmas Day; and in coun-ties on the day next but two after the day fixed for election. On the day next after the close of the poll (in counties on the day next but one), the returning officer is to open the poll-books and declare the state officer is to open the poll-books and declare the state of the poll, and make proclamation of the member or members chosen, not later than two o'clock in the afternoon of that day. The election being closed, the officer returns the writ, with the names of the persons elected by the majority, to the clerk of the crown in chancery, to whom also the poll-books are to be delivered for their future safe-custody. The candidate is considered to be a member of parliament from the moment of the declaration of the poll, although he does not act as a legislator until he has taken the baths. No person is competent to vote at the election oaths. No person is competent to vote at the election of a member of parliament unless his name appears on the register of electors; but in the case of one so registered no exception can be taken at the time of polling. In order to prevent bribery, treating, and intimidation at elections, the returning officers are now required annually to appoint certain officers, called election auditors, whose duty it is to take and publish an account of all expenses incurred at elecpublish an account of an expense incurred a second tions; and any payment in respect of any election made otherwise than by or through the election auditor is declared to be illegal. Bribery, if proved, involves the disqualification of the elector, and the unseating of the member chosen, if brought home to him.

ELECTION COMMITTEES.—At the beginning of every session of parliament the Speaker appoints by warrant six members of the House as "the General Committee of Elections." The members must be willing to serve, their seats must be unquestioned by petition, and they must not themselves be petitioners against any election. The Speaker's warrant is laid upon the table of the House, and if not disapproved of in the course of the three next sitting days, it takes effect. To this committee all election petitions are referred, and it is their duty to choose a committee for the trial of each petition, called therefrom an "Election Committee". Fash election committee. tee." Each election committee consists of a chairman and four other members of the House; the former of whom is chosen by and from out of a select body called the chairmen's panel (appointed to serve for that session by the general committee), and the latter by the general committee itself. This select committee, who general committee itself. This select committee, who are sworn truly and faithfully to try the matter before them, and are required to examine all witnesses on oath, then proceed to try the merits of the return or election (admitting no evidence, however, against any voter, or in support of any objection, not set forth in the list of voters, and objections which had before been delivered to the general committee), and determine whether the sitting members, or either of them, or any whether the sitting members, or either of them, or any or what other person, were duly returned or elected, or whether the election be void. Such decision, being final between the parties to all intents and purposes, is reported to the House at large, and entered in their journals.—Ref. Stephen's Commentaries on the Laws of England; May's Law of Parliament.

Elector, e-lek'-tor (Lat., from electum, supine of eligers, to choose), a dignity which is now merely nominal, the privileges that were formerly attached to it being lost, and the title retained by the ruler of Hesse-Cassel alone. It was originally applied to the high potentates of the empire, who claimed the right

high potentates of the empire, who claimed the right high potentaces of the empire, who claimed the right of participating in the election of the emperor. By the Gciden Bull of Charles IV. of Germany, which was accepted and confirmed by the diet of Nuremberg in 1856, the exercise of this privilege was restricted to a few of the leading princes and ecclesiant and the state of the s structed to a lew of the leading princes and ecclesia-tics, and it ultimately became hereditary in certain families, and confined to the king of Bohemia, the electors of Brandenburg and Saxony, the elector-palatine of the Rhine, and the archbishops of Co-logue, Treves, and Mayence. Bayaria became an electorate under Maximilian the Great in 1823, and Hanover in 1692, under Ernest Augustus, bishop of

## Electrical Machine

were lost at the dissolution of the Holy Roman empire by Napoleon in 1806, the last emperor, Francis II., having abandoned the title of emperor of Germany for that of emperor of Austria in 1804. The title had fallen into disuse, to a certain extent, long before this event, from the elector of Brandenburg having become king of Prussia in 1701, the electors of Saxony kings of Poland in 1897 and 1733, and the elector of Hanover king of Great Britain and Ireland in 1714. Bayaria, Saxony, and Hanover were erected into kingdoms in 1805, 1806, and 1814 respectively, when the rulers of each finally abandoned the title of elector for that of

ELECTRIC, e-lek-trik (Gr. elektron, amber), in Phys., the term generally applied to a substance which may, under ordinary circumstances, be readily made to evince electrical properties by friction. Amber is a powerful electric, and its property of attracting light particles of matter when rubbed was known to the ancients. From the Greek word for amber, the terms electric, electricity, electroscops, and many others, are derived. Electrics do not transmit, or conduct, electricity; hence they are frequently termed non-conductors, or insulators; whilst, on the other hand, anelectrics (which see) are transmitters, or conductors, of electrical action. The most perfect electrics are shell-lac, sulphur, am-The most perfect electrics are abel-lac, sulphur, amber, jet, resinous bodies, gums, gun-cotton, glass, silk, diamomd, agate, tourmaline, dry fur, hair, wood, feathers, paper, turpentine and various oils, dry atmospheric air and other gases, steam of high elasticity, and ice at 0° Fah. (See Electricity.)

Electric Light. (See Llumination.)

ELECTRICAL EEL (Gymnotus electricus) .traordinary fish is an inhabitant of the firesh-water traordinary his is an inhabitant of the hresh-water lakes and rivers of the warmer regions of America, Africa, and Asia. A specimen more than three feet in length was preserved alive in London between the years 1838 and 1842, and was examined by a great many electricians. Like the torpedo (which see), it has the power of giving electrical shocks; which power it exerts for killing or atunning the fishes upon which it feeds. Its body is smooth and without scales. A long ventral fin extends from behind the head to the extremity of the tail; the mouth is armed with sharp teeth, and projecting into it are numerous fringes, that, from their nature, appear to serve a purpose in respiration. The gullet is short, terminating in a ca-pacious stomach. The electrical organs are situated on pacious stomach. The electrical organs are situated on each side, and consist of flat purtitions or septa, and cross divisions between them. The outer edges of these sents appear, when the skin of the body is turned over, in parallel lines, nearly in the direction of the longitudinal axis of the body. They are thin membranes nearly parallel to one another, their breadth being nearly the semi-diameter of the body. A powerful shock is felt when one hand is placed near the head and the other near the tail. By the electricity generated by the specimen exhibited in England, Faraday magnetized steel needles, and decomposed iddied of magnetized steel needles, and decomposed iodide of potassium with the greatest case. A single medium discharge from the animal is calculated to be equal to the electricity of a Leyden battery of fifteen jars, containing 3,500 square inches of coated glass, charged to the highest degree.

ELECTRICAL MACHINE, an instrument for the excitation and collection of electricity. The earlier elecsimple glass tubes or rods of sulphur, which were held in the hand and excited by friction with silk or flamel. The first idea of a machine originated with the celebrated Otto Guericke of Magdeburg, who mounted a globe of brimstone on an axis, and caused it to revolve rapidly against the palm of the hand. For the globe of brimstone Dr. Hauksbee afterwards substituted a globe or glass; and Professor Winkler, of Leipsic, rendered the apparatus much more useful and convenient by affixing a cushion of soil leather stuffed with horse-heir, so that, by the pressure of a spring, it might rub against the revolving globe. In the electrical machines Onsburg. In 1778, Bavaria was united to the pulanow in use, the electric be excited is either a hollow
tinate of the Rhine, and the number of electorates was
cylinder or a circular plate of glass. For most purreduced to eight. Some minor electorates were created

pillars, A, A, usually of glass, which are fixed to a firm wooden base. Pressing against the cylinder is a flat cushion or rubber of coarse oiled silk, stuffed with wool or hair. This may be also fixed on an insulating pillar of glass. In the annexed figure, however, it is supported by a hinged wooden pillar B, which

ELECTRICAL MACRINE.

is drawn towards the cylinder by an elastic band placed over a block of wood, C. A long flap of thin silk, oiled on the upper side only, is sewed to the cushion, and rasts upon the upper half of the cylinder. Opposite the loose edge of this flap is a row of metallic points connected with a metallic cylinder called the conductor, D, which is also supported by an insulating glass pillar. When the glass cylinder is put in motion by means of the winch attached to one of its pivots, the two kinds of electrical power which, when combined neutralize each other, are one of its pivots, the two kinds of electrical power which, when combined, neutralize each other, are developed, the conductor becoming charged with vitrous or positive electricity, and the cushion with resinous or negative electricity. When it is requisite to obtain vitrous electricity for charging jars or other purposes, the cushion must be connected with the action of the chain vitrous exists in vidential the charinity of the connected with the charge of the charge that the charge the connected with the charge that the charge the charge that the charge the charge that the charge t purposes, the cusmon must be connected with the earth by a chain or wire, in order that the electricity drawn from the glass by the points of the conductor may become continually replaced by that supplied from the earth. If it be required to collect resinous electricity, this arrangement must be reversed. The conductor must be connected with the earth, and the body to be charged must be presented to the insulated cushion. The plate-glass machine was devised by Van Marum about the year 1776. As constructed by Cuth-bertson some few years after, the machine consisted of a circular disc of plate glass, from two to seven feet in diameter, mounted on an horizontal axis of metal, and sustained by a vertical frame of wood, to which were attached two pairs of cushions, one above and the other below. The plate was turned round between the rubbers by a winch fixed to the extremity of the axis. The electricity was contined by flaps of oiled silk, extending from each pair of cushions round nearly one fourth of the circumference of the plate, and was then collected by two rows of points opposite its horizontal diameter, and communicating with an insulated metallic conductor. The plate-machine, as originally constructed, was not adapted for the collection of resinous or negative electricity; but it has lately been so modified that this defect has been completely overcome. Sir W. Snow Harris, in his "Rudimentary Electricity," describes a most effective arrangement, calculated to describes a most effective arrangement, calculated to meet every difficulty in the use of the glass plate for both kinds of electricity. There are several instruments for exciting and collecting electricity besides the cylindrical and plate machines. (For notices of these, see Battrary, Electrical and Voltaic; Electrometous: Hydro-electric Machine; Induction

see BATTERY, ÉLECTRICAL and VOLTAIG; ELECTRO-THORUS; HYDRO-ELECTRIC MACHINE; INDUCTION COIL; JAR, ELECTRICAL.)

ELECTRICITY, e-lek-tris'-e-te (Gr. elektron, amber, the substance in which electrical properties were first recognized), the name given primarily to one of the great forces of nature, and secondarily to that branch of physical science which has sprung from the investi-gation of phenomena depending on this particular force. The ancients were well acquainted with the fact that certain bodies, when rubbell, acquire the power of attracting light particles of matter. Thales of Mile-tus, the founder of the Lonic philosophy, who flourished

#### Electricity

some 600 years before the Christian era, developed this attractive property in amber by friction, and con-cluded that the substance was animated by an unknown spirit or element. Theophrastus, some centuries later, observed the same attractive property in a crystal termed the lyncurium, now supposed to be the tournaline. Pliny and other naturalists refer to the sttractive power of amber as something well known, but say nothing to lead us to suppose that their knowledge say nothing to lead us to suppose that their knowledge of electrical phenomena went beyond the discoveries of the old philosophers. The first attempt towards a generalization of electrical phenomena was made near the close of the 16th century, by Dr. William Gilbert, in a treatise on the Magnet. In the following century, Dr. Wall, Boyle, Newton, and others, socumulated many new facts; but these were not of a nature to lead to the discovery of general principles. The electric spark was first noticed by Dr. Wall. In the early part of the last century, Dr. Hauksbee made many electrical experiments, from which he sacertained that glass was a substance which could be readily electrified by friction; and that some other bodies, especially metals, a substance which could be readily electrified by friction; and that some other bodies, especially metals, treated in the same manner, manifested no electrical power whatever. In 1728, Mr. Stephen Grey, a pensioner at the Charterhouse, performed a number of experiments which led to the discovery of electrical conduction, and to the classification of bodies into conductors and non-conductors. The conclusions arrived at by Grey were firmly established by the briliant researches of Du Fsy, a Freuch philosopher, to whom we are indebted for the discovery that there are two opposite states of electrical excitation, in which forces are developed attractive of each other. In 1745 forces are developed attractive of each other. In 1745 and 1746, numerous attempts were made to confine electricity in glass vessels containing water or mercury; and, almost simultaneously, Von Kleist in Germany, and Cunzus in Holland, became acquainted with the disagreeable effects of the electric shock. Muschenbrock, of Leyden, repeated the experiments of Cunzus, and published a wonderful report of the effects of the shock received from the apparatus, which is still known as the Leyden jar or phial. The discoveries of Franklin followed soon after, and greatly advanced the science of electricity. By a series of beautiful experiments with a common kite, this celebrated philosopher ascertained what had been before conjectured, that lightning was an electrical phenomenon. Carendish afterwards was an electrical phenomenon. Cavendish afterwards entered with great spirit into the field of electrical research, and thoroughly investigated the conditions of bodies charged with electricity. About the year 1799, Galvani, of Bologna, discovered that the mere contact of metals with the muscles and nerves of a frog contact of metals with the muscles and nerves of a frog recently killed produced convulsive motions; and, by repeating Gaivani's experiments, the celebrated Volta, a professor of natural philosophy at Pavia, was led to the discovery of the apparatus now known set he Voltaic pile, a discovery which gave rise to a new branch of electrical science, which is termed galvanism, or, more correctly, Voltaic electricity. Davy's researches proved that the voltaic current was a most potent agent in chemical analysis. Oersted discovered, in 1820, that the current exerted a peculiar influence on the magnetic needle, and founded the science of electro-magnetism, which was soon afterwards fully developed by Ampère. which was soon afterwards fully developed by Ampère. Faraday, in his "Experimental Researches in Elecpublished between 1830 and 1840, described tricity," published between 1830 and 1840, described the phenomena of volts-electric and magneto-electric induction, and thus established the beautiful science of magneto-electricity. Seebeck, of Berlin, found that an electric current may be generated by the unequal effects of heat on different metals in contact, and gave the name of thermo-electricity to the new branch of science which sprung from this observation. Among the modern electricians to whom the world is greatly indebted are Grove, Wheatstone, Becquerel, Pouillet, Jacobi, Spenser, De la Rive, Harris, and Henry. The peculiar power which we call electricity is only known to us by its effects, and such terms as electric fluid and to us by its effects, and such terms as electric fluid and electrical current are to be understood as figurative expressions. Many theories respecting the nature of electricity have been advanced for the purpose of explaining electrical phenomena. That of Du Fay and Symmer supposes electricity to be an infinitely attenuated fluid pervaging all bodies, and composed of two primary elements possessing distinct and opposite

# Electricity, Atmospheric

Electricity, Frictional

properties. These elements, called viercous and resinous electricities, are supposed to neutralize each other when combined, electrical repose being the result. When, however, a disunion of these elements takes place, each becomes active. In accordance with this theory, electrical excitation consists in a separation and abstraction of one of the elements, leaving the other in excess or uncompensated. The theory started by Frankin supposes the existence of a single homogeneous imponderable fluid of extreme tenuity and clasticity, in a state of equable distribution throughout the material world. This fluid is assumed to be out the material world. This fluid is assumed to be repulsive of its own particles, but attractive of all other matter. When distributed in bodies, in quantities proportionate to their capacities or attraction for it, such bodies are said to be in their natural state. When we increase or diminish the natural quantity of electricity in any substance, excitation is the result, and the substance, if overcharged, is said to be electrified positionly, or, if undercharged, negatively. The theories of Eules and Cavendish are less defective than those of Du Fay and Franklin, upon which they are respectively based; but even these are now found to be inadequate for the elucidation of electrical phenatural of the change of the control phe-momens. Adopting the views of Faraday, scientific men of all nations now recognize two kinds of elec-trical force, distinguished by the terms positive and negative, but do not assume the existence of any pe-culiar kind of matter to which the term sleetic fluid may be applied. For a lucid exposition of Faraday's theoretical views of electrical action, the reader is referred to Sir W. Snow Harris's "Rudimentary Treatise on Electricity." As the various branches of electricity on Electricity." As the various branches of electricity are generally considered as distinct sciences, they are are generally considered as distinct sciences, any are treated separately in this work. The following are the principal heads under which electrical phenomena are described:—ELECTRICITY, FRICTIONAL; ELECTRICITY, VOLTAIC; ELECTRO-CHEMICAL THEORY; ELECTROLY-SIS; ELECTBO-MAGNETISM; MAGNETO-ÉLECTRICITY; LIGHTNING BED THUNDES. The more important electrical machines and instruments are noticed under BATTERY, ELECTRICAL and VOLTAIC; ELECTRICAL MACHINE; ELECTROPHORUS; ELECTROSCOVES and ELECTROMETERS; HYDRO-ELECTRIC MACHINE; IN-DECTION COIL; JAR, ELECTRICAL. For information respecting the chief practical applications of electricity, see Electro-MOTUS POWER; ELECTRO-PLATING AND GILDING; ELECTROTYPE; LIGHTNING-CONDUCTOR; TELEGRAPHY; ILLUMINATION.

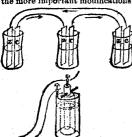

ELECTRICITY, ATMOSPHERIC, the term applied to electricity as a natural agent existing and acting in the atmosphere. Electricity is called into action upon a grand scale in the thunderstorm. How the electric accumulation takes place is a subject that has never been clearly ascertained, but it probably results from a variety of causes, and is also connected with some peculiar power in masses of aërial vapour, which enables them to receive and retain electrical charges. The analogy between lightning and electricity seems to have been first noticed by the Able Nollet, in 1748. It was afterwards verified by Benjamin Franklin, at Philadelphia, in 1752. (See LIGHTNING.) There is still very little known about the cause of atmospheric There is electricity. The many changes which are continually occurring on the surface of the earth and in the sur-rounding atmosphere are, doubtless, of such a nature rounding atmosphere are, doubless, of such a nature as to disturb the electric equilibrium. Evaporation, change of state or form in the varieties of matter, changes of temperature, chemical action, all these combined, asem to produce those enormous electrical accumulations called thunderstorms. (See Thunder, Thundersonm.) The beautiful phenomens of the aurora borealis is most probably connected with, or dependent upon, atmospheric electricity. (See Aurora Berralis.) All meteors were at one time considered as derived from electricity; but the showers of stones by which many of them are accompanied show that they must be ascribed to other sources. (See Metros, Merrosio Storks.) Those bodies called falling stars are considered by many to have an electric origin. They are most common when the atmo-aphere is favourable to electric accumulation.

from those comparatively new sciences which have reference to the phenomena attendant on electrical excitation by chemical action, magnetism, and heat.
If a stick of seuling-wax be rubbed with a dry piece of it as stated is a state with a try piece of faunci or cloth, it becomes electrified, in other words, it acquires the power of attracting light bodies, as feathers, wafers, or bits of paper. Many other substances besides sealing wax can be readily electrified by friction, and such substances are termed electric by friction, and such such such such as are termine section (which see). If a light, down, feather be suspended by a flue thread of white silk, and a dry glass tube, excited by rubbing, be presented to it, the feather will be strongly attracted to the tube, will adhere to its surface for a few seconds, and will then fall off. the tube be now excited anew, and presented to the feather, the latter will be strongly repelled. same experiment may be repeated with the stick of scaling-wax; the feather, in its ordinary state, will be drawn towards the excited body, and after touching again driven from it with a certain degree of force. Now, let the feather be brought into contact with the excited glass so as to be repelled by that substance, and let the excited sealing-wax be presented to it, a degree of attraction will be observed far exceeding that exhibited when the feather is in its ordinary state. Or, again, let the feather be made repulsive for sealing-wax, and then let the excited glass be presented; strong attraction will ensue. These experiments prove that there are two opposite kinds of electrical excitement, and that a body, to which one kind has been communicated, is attracted by another body in the opposite state, and repelled by one in the same state. It is customary to call the electricity manifested by glass positive or vitreous, and that developed in the case of sealing wax and bodies of the same class, negative or resingue. The kind of electricity resulting from friction appears, however, to depend on some peculiar condi-tion of contact between the rubbed surfaces; thus smooth glass rubbed with silk or wool becomes positive, but when roughened by sand or emery it acquires, under the same circumstances, a negative charge. Again, when silk is rubbed with glass, it becomes negative, but when rubbed with sealing-wax, positive. Both tive, but when rubbed with scannig man products whinds of electricity are produced in every case of electrical excitation, the rubber and the rubbed body always assuming opposite states. There are many always assuming opposite states. There are many substances which cannot be excited in the ordinary way, though they may be electrified by placing them in communication with an excited electric. are termed anelectrics (which see), or more correctly conductors, from their property of conducting the electrical force. If an electrified pith-ball, suspended by a silk thread, be touched by any electric,—a stick of dry scaling wax for instance, its attractive power will not be in any sensible degree impaired; but if it be touched with any conductor in communication with the ground, it will instantly lose its electrical charge. It is therefore evident that electrics are non-conductors, or insulators, and that anelectrics are transmitters, or conductors, of electrical action. Modern researches have, however, proved that the difference between the two classes is only one of degree, not of kind; the very best conductors offer a certain resistance to the electrical discharge, and the most perfect justila-tors permit it to a amail extent. The metals are by far the best conductors; shell-lac, sulphur, glass, silk, and dry gas, the worst. Electrical discharges take place silently and without disturbance in good conductors of sufficient size; but if the charge is very intense and the conductor very small, or imperfect from its nature, it is often destroyed with violence. When a break is made in a conductor employed in effecting the discharge of a highly-excited body, disruption or spark-discharge takes place across the intervening air, provided the ends of the conductor be not too distant. The electrical spark itself presents many points of interest in the modifications to which it is liable. The time of transit of the electrical force it is liable. The time of transit of the electrons force through a chain of good conducting bodies of great length is so minute as to be altogether inappreciable to ordinary means of observation. An electrified body exerts a peculiar influence upon neutral conducting bodies at sensible and even considerable distances. BLECTRICITY, FRICTIONAL.—By this term, that de-partment of physics which relates to the phenomena of ordinary electricity may be conveniently distinguished duction, may be thus examined:—Let two small cylin-

ders of metal be insulated upon supports of glass varnished with a solution of shell-lac in spirits of wine, and let these insulated conductors be placed end to end at a short distance apart. Now, if one conductor be charged with positive electricity, it will induce a negative state in the nearer portions of the other, and a positive state in the more remote parts. The precise condition of the second conductor cannot be properly investigated without the aid of the most delicate electroscopes; but with a suspended pith-ball the attractive power of its distant extremity may be readily detected. On removing the electrified conductor, the second conductor at once loses its attractive power. For experiments on electrical attraction two power. For experiments on electrical attraction and repulsion, a large glass tube will be found very useful. To excite it, the rough side of oiled silk (oiled only on one side) rubbed over with aurum musicum (which see), may be used; or, if such a rubber cannot readily be procured, a dry soft silk handkerchief may be employed. To exhibit the mechanical, luminous, and heating effects of the electrical discharge, we require an electrical machine (which see), and for the accumulation of electricity of great intensity we demand, in addition to this, those powerful instruments the jur and bottery. (See these words.)
ELECTRICITY, MEDICAL. (See ELECTRICITY, VOL-

TAIC; INDUCTION-COIL.)

ELECTRICITY, VOLVAIC, or GALVANISM, the science which relates to the phenomena connected with a peculiar form of electrical force obtained by certain arrangements of netals and liquids. Galvani, a pro-fessor of anatomy at Bologue, in 1789, made the dis-covery that the transmission of electricity through the nerves of a frog, recently killed, would excite muscular contractions; and he afterwards found that similar convulsions could be produced by merely touching the nerves and muscles with two different metals and then bringing the metals into contact. Upon these and similar phenomens, observed in an extended series of experiments with different animals, Galvani based his theory of "animal electricity," which was received with enthusiasm by the Italian physiologists of his day. According to this theory, every animal is endowed with an inherent constitutional electricity, generated in the brain and distributed through the nervous sysa professor of natural philosophy at Pavia, repeated Galvani's experiments, and proved that the contractions in the muscular fibre depended, not on any peculiar electrical condition of the animal frame, but on a feeble action derived from the metals with which the nerves and muscles were brought into contact. determine the exact conditions under which electrical disturbance is produced, he commenced a course of disturbance is produced, no commenced a course of experimental researches on the energies of different metals, which eventually led him to the discovery of the pile, an apparatus which must be regarded as the source of all the great discoveries relating to electricity made in modern times. The original voltaic pile, and the more important modifications of it which are now

in use, are fully described under the head of Bar-TRHY, VOLTAIC. The opposite figs. represent three cells of Volta's couronne des tassea, or crown of cups, the most simple modifica-tion of the pile, and a single cell Professor Daniell's conbattery. stant The arrows show

taken by the positive current out of the battery, taken by the positive current out of the battery, positive to the zine, the current in the reals being from the copper to the zine, the current in the reals being from the zine to the copper. Two theories have been offered in explanation of the action of the voltaic pile or battery. The contact theory of volta assumes that different metals have different volta assumes that different metals have different radius electrical capacities, and that electrical disturbance radius electropositive pole. (See Electrical capacities, and that electrical disturbance radius electropositive. When an electric current in the pole to the capper. In the pole to the compound with sufficient pole of the battery, and the other electro-positive. When an electric currely in the pole to the compound with sufficient pole to decompose it, its electro-negative constituent pole of the battery, and the vire connected with the positive pole of the battery, and the vire connected with the positive pole of the battery. The compound with sufficient pole to decompose it, its electro-negative constituent pole to decompose it, its electro-negative constituent pole to decompose it, its electro-negative constituent pole of the battery. The contact theory of the battery are the vire connected with the negative pole of the battery. The contact theory of the battery are the vire connected with the negative pole of the battery.

results from simple contact. In applying this theory to the pile, or crown of cups, it is assumed that each zinc plate takes electricity from the copper plate in contact, or connected with it, and at the same time discharges electricity through the moist or fluid conductor into the next copper plate. This theory is embarrassed by anomalies and improbabilities, and has been rejected by most scientific men. The chemical theory, new generally adopted, assumes that the chemical action set up between the solids and liquids of the pills in the source of its new of the pills of the pills in the source of its new of the pills of the pills in the source of its new of the pills of the pill mical action set up between the solids and liquids of the pile is the source of its power. The facts which support this theory are very numerous, and most of them are inexplicable when viewed by the light of the contact theory. Faraday and others have proved that chemical action does give rise to electrical force; that when the chemical action of a battery diminishes or ceases, the voltaic current also diminishes or ceases; and that powerful currents may be generated without and that powerful currents may be generated without bringing dissimilar metals into contact. There is, indeed, every ground for supposing that chemical silinity and electricity are merely modifications of one aminty and electrony are active.

force. (See Electronysis.) The ourrent force of the voltaic battery has been practically applied to many useful purposes. It is employed in telegraphy (which see) to deflect magnetic needless at a distance of hundreds of miles in such a manner that alphabetical signals may be determined by the direction and number of converting iron ber of the deflections. Its power of converting iron bars into temporary magnets of unlimited power has been taken advantage of in the construction of electromotive engines and clocks. (See ELECETRO-MOTIVE Powen; Horology.) Its power of causing chemical decomposition has been turned to account by the metal-worker, the engraver, and the calico-printer. (See Electrotype; Electro-plating and Gilling; Electro Calico-printing.) The current is also much used as a remedial agent in the treatment of many forms of disease of the human body; decided relief has been obtained in paralysis, lock-jaw, St. Vitus's dance, tic-doloreux, and deafness. Though the term galvanism is still commonly applied to the science relating to the current force, it is certainly less appropriate than either rolluic electricity or rolluism, for the observations of Galvani were unimportant compared with those of his great follower, Volta.—Ref. Sir William Snow Harris's Rudimentary Treatise on Galvarism.

ELECTRO CALICO-PRINTING, the art of producing patterns on cloth by the chemical action of the voltaic patterns on cloth by the chemical action of the voltaic current. Many processes of electro calico-printing have been introduced, but as yet they are only used to a limited extent, and it is not likely that they will ever supersede the ordinary effective processes of calico-printing, which depend on chemical action alone. (See Calico-Pennting.) The following example will give the reader a general idea of the electro-chemical methods:—A white pattern is to be printed on a blue ground. The cloth having been wetted with very diluto by dypochlavia acid. is placed on a sheet of tinfoil or hydrochloric acid, is placed on a sheet of tinfoil or other conducting surface connected with the negative electrode of a voltaic battery. A plate of iron, upon which the required pattern has been painted in var-nish, is now connected with the positive electrode of the apparatus, and applied to the cloth. Electro-chemical action is at once set up, and the exposed por-tions of the metallic surface are dissolved by the acid, and the charded is from thus formed becomes fixed in and the chloride of iron thus formed becomes fixed in the cloth. To develop the pattern, the cloth is now passed through a bath of prussiate of potash, which produces a beautiful blue colour wherever the iron has touched, but which does not affect the parts which

touched, but when does not seem the varnish has shielded.

ELECTRO-CHEMICAL THROBY.—In Chem., a theory founded by Davy and Berzelius to account for the chemical changes that take place in substances during their formation or decomposition. It assumes that the constituents of every binary compound are always in opposite electrical states; one being electro-negative and the other electro-positive. When an electric current is passed through such a compound with sufficient force to decompose it, its electro-negative constituent is disengaged at the wire connected with the positive

### Electrode

Electrolysis

been classified according to this theory. Thus hydrogen metals and their oxides belong to the class of electro-positive substances, while the non-metallic ele-ments and the soids belong to the other class. It must be borne in mind, however, that the distinction is only relative, as a substance may be electro-positive to one body, but electro-negative to a third. Sulphur, for instance, is electro-negative to silver, but electro-positive to chlorine.

ELECTRODE, e-lek-trode (Gr. elektron, amber; odos, a way), a term substituted by Faraday for the term pole, as applied to one of the terminations of a voltaic battery. It signifies the way or door by which a current

enters or leaves a substance. (See Electrolysis.)
Electro-Dynamics. (See Electro-Magnetism.) BLECTRO-DYNAMICS. (See MERRY-MARKISE.).

BLECTRO-BYOLING, a mode of etching based upon the destructive action of certain anions upon metals during electrolysis (which see). If two plates of copper be connected with the opposite ends of a voltaic battery and placed in a vessel containing water mixed with a little sulphuric acid, the plate connected with the a little suppuric acid, the plate connected with the positive end will be attacked by the anion oxygen, which is released during the decomposition of the water. This destructive action can be localized at pleasure, by covering certain parts of the plate with a protecting stratum of varnish. Now, as ordinary etching-ground effectually shields a plate from the effects of electrolytic action, it is evident that a drawing traced through the ground in the ordinary manner may be etched without difficulty by exposing the plate to the action of the nascent oxygen. A stout wire must be soldered to the plate; and this, as well as the back of the plate, must be varnished with a solution of shell-lac in spirits of wine. Thus prepared, the plate is placed in a decomposition-cell opposite a plate of somewhat similar size, and the two are connected respectively with the copper and the zinc of a Daniell's respectively with the copper and the zino of a Bannell sor a Smee's cell. (See Batter, Voltaic.) After a lapse of about ten minutes, the prepared plate is removed, for the purpose of "stopping out" the fine parts of the design with Brunswick black. This operation having been completed, the plate is returned for auother space of ten minutes. The half-tints are thus stopped out, and the plate is once more exposed to the action for ten minutes, in order that the stronger lines of the drawing may be deepened. The etching is now completed, and the ground is removed by means of heat. The exact duration of the several exposures, as well as their number, must, of course, be regulated by circumstances. To etch upon iron or steel, a solution of common salt may be used as an electrolyte, and to etch upon silver, a solution of sulphate of silver. The mode of etching above described is, in many respects, superior to the common mode by the use of acids. The whole operation can be conducted with considerable regularity, and can be rendered slow or rapid at pleasure. Again, the plate can be taken out of the decom-position-cell from time to time to be examined, and can be re-submitted to the electrolytic action in a

ELECTROLYSIS, e-lek-trol'-e-sis (Gr. elektron, amber; luo, I loose), a term applied by Faraday to the process of electro-chemical decomposition. The voltaic current of electro-chemical decomposition. The voltaic current has the power of locening and separating the elements of certain compounds when these are interposed in the circuit. The substances which are thus susceptible of decomposition are termed electrolytes. They are all binary compounds, containing single equivalents of their components, which are held together by very powerful affinities. The amount of electrical power required to effect decomposition varies greatly with different electrolytes: solution of iodide of potasium, melted chloride of lead, hydrochloric acid, water mixed with a little sulphuric acid, and pure water, demand very different degrees of decomposing force, the resistance increasing from the first-mentioned sub-

ing perfectly quiescent. Faraday has proposed the terms anode and cathode respectively for the surfaces which are supposed to receive and let out the current which are supposed to receive and let out the current of positive electricity. The anode is therefore directly against or opposite the positive pole of the battery, or, according to Faraday's nomenclature, the positive electrode; and the cathode against or opposite the negative pole or electrode. The bodies which are set free by electrolysis are termed ions. Those ions which to the product of a possite at the positive electrode. go to the anode, and appear at the positive electrode or pole, are distinguished by the term anions, and those which go to the cathode, and appear at the negative electrode, by the term cathions. In the old phraseology of the electro-chemical theory (which see), anions would be called electro-positive bodies, and cathions electronegative bodies, from the assumption that they are under the influence of direct attractive forces residing in the opposite poles of the battery. Faraday has shown by conclusive experiments that the decomposing forces in the state of the s force is not at the poles, but within the substance which is acted on by the current; and the new terms introduced by him express the phenomena actually observed in all cases of electro-chemical decomposition. The following illustrations of electrolysis are particularly striking:—When a pair of platinum plates are plunged into a glass of water to which a few drops of sulphuric acid have been added, and the plates con-nected by wires with the extremities of an active voltate hattery, the water is decomposed into its two consti-tuents, oxygen and hydrogen gases; the former being tuents, oxygen and hydrogen gases; the former being disengaged at the positive electrode, and the latter at the negative electrode. The sulphuric acid is added to the water merely to increase its conducting power. A solution of hydrochloric acid coloured with a little Saxon blue, and treated in the same manner, yields hydrogen at the negative electrode and chlorine at the calific and acid at the same manner. positive, where its presence is made evident by the indigo becoming bleached. Iodide of potassium is decomposed in a similar manner, with still greater ease; and the free iodine at the positive electrode can be recognized by its brown colour or by the addition of a little gelatinous starch, with which it forms a lovely blue compound. The decomposition of water by the voltaic current was first observed by Messrs. Nicholson and Carlisle, and their discovery caused a great sensa-tion in the scientific world. The researches of Davy on the chemical effects of the current led soon after to on the chemical effects of the current led soon after to the great discovery that the alkalies, soda and potassa, and the earths, which had hitherto been regarded as elementary bodies, contained metals. This dis-covery, which was announced in 1807, proved that the voltaic pile was an instrument of immense im-portance in chanical investigations. To Davy's great pupil and auccessor, Faraday, the world is indebted for the clucidation of beautiful phenomena attend-ant on electrolysis. From a very extended series ant on electrolysis. From a very extended series of experiments he was enabled to draw the general inference that the effects of chemical decomposition were always proportionate to the quantity of circu-lating electricity, and might be taken as an accurate and trustworthy measure of the latter. Guided by this important principle, he constructed his voltameter, an instrument which has rendered the greatest service by which a little soidulated water is decomposed by the current, the gas evolved being collected and measured. By placing such an instrument in any part of the circuit, the quantity of electrical force necessary to produce any given effect can be at once estimated; or, on the other hand, any required amount of the latter one be as it ware measured out and adulted to the on the other hand, any required amount of the latter can be, as it were, measured out and adapted to the object in view. Experiments performed with the aid of this instrument led to the important discovery that the relative decomposing effects produced by the same current in different electrolytes is exactly expressed by the atomic weights or chemical equivalents of the electrolytes. Thus if a current be made to traverse demand very different degrees of decomposing force, the resistance increasing from the first-mentioned substance to the last. One of the indispensable conditions of electrolysis is fluidity; for bodies which, when reduced to the liquid state by fusion or solution, recollectrolysis is fluidity; for bodies which, when reduced to the liquid state by fusion or solution, for electrolyses, and readily suffer decomposition, are frequently absolute insulators when solid. When a liquid is electrolysed, its components are disengaged solely at the limiting surfaces, where, scoording to the usual flagrative mode of speech, the current enters and pleaves the liquid, all the intermediate portions appear-lectrical machine, though only on a very minute

This arises from the small quantity of elec scale. This arises from the small quantity of electricity set in motion by the machine, as compared with that generated by the voltaic battery. A pair of small wires of sine and platinum dipping into a single drop of dilute acid develop far more electricity to judge from the chemical effects of such an arrangement, than very many turns of a large plate electricity generated by the machine depend on its tension, or that property which enables it to overcome difficulties, and pass through imperfect conductors. The electroand pass through imperfect conductors. The electrolysis of metallic salts is now carried out on a large scale in the beautiful arts of electrotype and electrolysis (which see). The more recent arts of electroetching, galuanography, and electro culco-printing (see these words), are also based upon the chemical action of the voltaic current .- Ref. Fownes's Manual of Che-

mistry; Harria's Rudimentary Treatise on Galvanism.

ELECTRO-MAGNETISM, e-lek'-tro-mag'-ne-tizm, a important branch of electrical science, which ma 8.0 may be said to have sprung from a discovery made by Professor Oersted, of Copenhagen, in the year 1920. The discovery of the Danish philosopher was thus simply stated:—When a properly balanced magnetic needle stated: - When a properly-balanced magnetic needle is placed in its natural position in the magnetic merian, immediately under and parallel to a wire along which a current of voltaic electricity is passing, that end of the needle which is situated next to the negative side of the battery immediately moves to the west; if the needle is placed parallel to and over the wire, the same pole moves to the cast. When the uniting wire is situated in the same horizontal plane as that in which the needle moves, no declination takes place; but the needle is inclined, so that the pole next to the negative end of the wire is depressed when the wire is situated on the west side, and elevated when situated on the east side. By this discovery the relation of magnetism to electricity, which had long been suspected, was satisfactorily established, and a new and boundless field of research was opened. One of the Faraday, who, reasoning on the fact that the action of a conducting-wire on a magnet is not a directly attractive or repulsive one, was led to the conclusion, that if the action of the voltaic current could be confined to one pole of the magnet, that pole ought, under proper conditions, to rotate round the wire; and conversely, if the magnet were fixed and the conducting-wire movable, the wire ought to rotate round the magnetic movable, the wire ought to rotate round the magnetic pole. Both of these phenomena he realized; and early in 1822 described the apparatus for exhibiting them. The apparatus employed to exhibit the rotation of the movable magnet consisted of a deep cup, nearly full of mercury, in which a cylindrical magnet was placed. The north pole of this magnet was allowed to project above the surface of the mercury, while its south pole was held down by a piece of thread attached to the end of a copper wire, which entered the cup through the centre of the base. The end of a second wire was made to dip into the mercury exactly over that at the bottom of the cup. By connecting the two wires with the two ends of a voltaic battery in action, whree with the two enus of a voiting observery in action, the current was made to pass through the mercury; and the magnet, buoyed up by the mercury, rotated about it. If the positive current descended, the rotation was in the direction from east through south to west: but if the current was made to ascend, then the direction of the motion was reversed. Ampère subsequently caused a magnet to rotate round its own axis; and Barlow devised an ingenious apparatus for exhibiting the rotation of a conducting body round its axis. The first useful application of Oersted's discovery of the reciprocal force exerted between magnetic bars and conducting-wires, was made by Schweigger, a German physicist, in the construction of an instrument for indicating the direction and measuring the intensity for indicating the direction and measuring the intensity of voltaic currents. (See GALVANOMETE.) The laws of electro-magnetic action were fully developed by Ampère, who must be regarded as one of the greatest philosophers of this century. In the course of his investigations he discovered a number of extremely interesting phenomena resulting from the action of all centuring and action.

two currents flowing in the same direction were made to approach each other, strong attraction took place to approach each other, strong attraction took place between them, and when in opposite directions, an equally strong repulsion. These effects have absolutely no relation that can be traced to ordinary electrical attractions and repulsions, from which they must be carefully distinguished. They are purely dynamic, having to do with electricity in motion; and hence they are generally treated of under the head of electro-ture in the electrons. dynamics. Upon those attractions and repulsions of ayamete. Open those attractions and repulsions or conducting wires Ampère founded a most beautiful and ingenious hypothesis of magnetic actions in general, which explains very clearly the influence of the current on the needle. He found that a striking analogy existed between wires conducting electricity analogy existed between wires conducting electricity and magnets, when the former were turned, corkserew fashion, into helices. A helix has indeed all the properties of a magnet, but the direction of the pole at either end will depend on the direction of the turns of the helix; if these be from left to right, then the extremity at which the current enters will have the magnetic properties of a north pole; but if the helix be a left-handed one, then the extremity at which the current enters will have the magnetic properties of a south pole. The analogy extends to fracture. If a magnetic bar be broken in two, each piece is a perfect magnet, and the fractured two, each piece is a perfect magnet, and the fractured parts have opposite poles; so it is with the helix, which, if divided in the middle, exhibits attraction between the fractured ends. Now, according to Ampère's theory of magnetism, the phenomena exhibited by a magnet depend on voltaic currents circulating round its molecules. In their unervited state these round its molecules. In their unexcited state, these molecular currents move in all directions, and thus neutralize one another; but when the bar becomes a magnet, the currents move parallel to each other, and in the same direction, and the effect produced is that of a uniform current moving corkscrew-fashion round the bar, which thus becomes in effect a helix, and the attractions and repulsions are consequences of the actions of the currents on each other. In applying this theory to the explanation of the phenomena of terrestrial magnetism, it is necessary to suppose the incessant circulation of electrical currents round the globe from east to west perpendicular to the maggiode from east to west perpendicular to the mag-netic meridian. (See Magnarism.) A consideration of the influence exerted by electrical currents on magnets naturally led to the conclusion that the neutral condition of bodies susceptible of magnetism would be disturbed by an electrical current, and this conclusion was quickly verified by experiments. When an electrical current is passed at right angles to a piece of tron or steel, the latter acquires magnetic polarity, either temporary or permanent, as the case may be, the direction of the current determining the position of the poles. This effect is prodigiously increased by causing the current to circulate a number of times round the bar, which then acquires extraordinary round the bar, which then acquires extracturary magnetic power. A steel bar may be permanently magnetized in this way, but a bar of pure and soft iron retains the magnetic force only so long as the electrical current is circulating round it. Bars of iron thus temporarily magnetized are called electro-magnets. They are usually horse-shoe shaped, and the conduct ing-wire, which is wound several times round them, is ordinary copper bell-wire, covered with silk or cotton for the purpose of insulation. The power of the electromagnet depends on the dimensions of the bar, the purity of the iron, the intensity of the current, and on the length and thickness of the covered wire. One the length and thickness of the covered wire. One has already been constructed which, when connected with a powerful voltain battery, attracts the iron keeper with a force equal to the weight of more than two tons. When it was discovered that magnets of great power could so readily be made and unmade, attention was naturally given to the application of electro-magnetism as a motive power, and many increase which has been considered with the legislativity was genious models of engines driven by electricity soon genous models of engines driven by electricity soon made their appearance. At the present time, there are many highly efficient electro-magnetic engines in existence, but the expense of working them prevents their application to ordinary purposes. (See Electro-MOTIVE POWER.) The application of electromagnetism to telegraphy has led to marvellous results. electrical currents on each other, which become TRO-MOTIVE POWER.) The application of electroevident when arrangements are made for giving momagnetism to telegraphy has led to marvellous results.
bility to the conducting-wires. He found that when Space and time have, in effect, been annihilated, and

## Electro-Metallurgy

the inhabitants of almost all the large towns of the civilized portions of the globe have been brought, as it were, within speaking distance of each other. A general description of the electric telegraph, with a sketch of the history of telegraphic communication, will be found under the head of TELEGRAPHY. Electromagnetism has been most successfully applied as a motive power to the mechanism of clocks. ROLOGY.) About ten years after Oersted's discovery, Faraday found that electrical currents could be de-veloped in metallic bodies by the action of magnetism. Out of this discovery arose an entirely new branch of electricity, which has been termed Magneto-Electricity (which see).—Ref. Noad's Manual of Electricity; Bir W. Snow Harris's Rudimentary Treatises on Magnetism and Electricity.

ELECTRO-METALLURGY, a comprehensive term for The application of electricity to metal-working. The more important branches of electro-metallurgy are fully described under the heads Electro-type, Electro-type, and Gilding, and Electro-type, Electro-type, and Electro-type, an

TROMETERS.)

ELECTRO-MOTIVE POWER .- The attractive force of the electro-magnet is applied with complete success as a motive power; and machines or engines driven by this force are rather extensively used in the fabrica-tion of mathematical and optical instruments. Compared with steam, electro-magnetism is a very costly agent, and, on this account, it cannot be employed for moving ordinary machinery. For small and delicate machines, however, electro-motive power is so excellently adapted, that its cost is not taken into consideration. ation. Its peculiar advantages are its noiseless action, portability, safety, controllability, and freedom from dirt. The colebrated Russian philosopher Jacobi first constructed electro-motive engines large enough to be practically tested. With one of these, he, in 1839, succeeded in working the paddles of a boat with such force, that the boat, with ten persons on board, attained the speed of four miles an hour. In 1812, Mr. Davidson made some experiments with an electro-motive engine with an electro-motive engine of his invention, and succeeded in propelling a carriage weighing five tons along a line of rails at the rate of four miles an hour. In America, Mr. Davenport and Professor Page successfully applied electro-magnetism to various machines; and in Denmark, Mr. Hjorth, in 1849 took out a nature for an electro-medical control of the contro 1849, took out a patent for an electro-motive engine of 10-horse power, which far surpassed all previous contrivances. To M. Froment, the celebrated mathematical-instrument-maker of Paris, the world is indebted for the proof that electro-magnetism could be advantageously used as a permanent and regular moving power in a large establishment. The electro-motive machines of M. Froment are very various in form, magnitude, and power; but they all derive their motion from magnetism temporarily induced in iron bars by the action of the electric current. (See Electro Magnetism.) By an expedient to which an infinite variety of forms may be given, the current round each iron bar, or electro-magnet, can be alternately transmitted and suspended with any desired degree of rapidity; and, by varying the power of the battery, the length of the coiled wire, and the magnitude of the bar, a magnetic force of any desired intensity can be produced. A piece of iron, called an armature, is presented to one or both of the poles of the electro-magnet, towards which it is attracted while the current is transmitted, with a force proportionate to the intensity of the magnetism; and when the current is suspended, the armature either falls from the magnet by its own weight, or is with drawn from it by the action of a spring or other mechanical arrangement provided for the purpose. The armature may be placed between two magnets, so as which is transmitted round each in the intervals of its suspension round the other. The armature will then be moved alternately to and fro between the two mag-nets. In this manner, by alternately suspending and transmitting the gureant on the wive which is called round the electro-magnet, the magnet and its armature receive an alternate motion to and from each other, similar to that of the piston of a steam-engine or the foot of a person who works the treadle of a lathe. This alternate motion is made to produce one of continued

## Electro-plating and Gilding

rotation by the same mechanical expedients as are used in the application of any other moving power. The force with which the electro-magnet and its armature attract each other determines the power of the electromotive machine, just as the pressure of steam on the piston determines the power of a steam-engine.— Ref. Lardner on Electro-Motive Power, in Museum of Science and Art. The construction of several of M. Froment's ingenious contrivances is there plainly described.

ELECTROPHORUS, e-lek-trof'-o-rus (Gr. elektron, and phoreo, I bear), a valuable instrument for exciting electricity, devised by Volta. In the chemical laboratory it is generally used instead of an ordinary electrical machine for charging small Leyden jars, when mixtures of gases have to be exploded by the electric spark. To construct it, a plate of tin is made into a circle of about twelve inches diameter; a raised border is then turned up for about half an inch, and the extreme edge is turned outwards over a wire, so as to avoid a sharp border. A mixture of equal weights of shell-lac, Venice turpentine, and resin, is made by gently heating them together until well fused, stirring during the time with a stick, so as to thoroughly incorporate the ingredients. The composition should, when perfectly homogeneous, be poured into the plate with the raised edges until it a suite full, and the composition is to be but mitted. is quite full, and the composition is to be kept melted, but not too hot, until the hubbles have entirely disap-peared. The second portion of the instrument, or that which serves the place of a conductor, consists of a flat circle of wood, rounded at the edge, and neatly covered with tin-foil: it is rather smaller than the resinous plate. An insulating handle, formed of a piece of stout glass rod, is cemented into the centre of the wooden disc. Before using the instrument, it must be carefully dried and stightly warmed. The resinous surface fully dried and signify warned. The resinous surned is to be excited by beating with a piece of warm flamnel. To do this effectually, the latter is to be folded into a slip about fourteen inches long, and, being grasped by one end, is to be struck upon the resinous surface smartly, and in an oblique direction, much in the manner of beating dust off a flat surface. When this has been done for about a minute, the warm dry cover or upper plate of the instrument is to be placed upon the resinous cake, and touched with the finger. If the cover is then raised a few inches, and the knuckle approached, a powerful spark of positive electricity will pass; and if the cover be again replaced, touched, and raised, a second spark will pass. This may be repeated many times without again exciting the resinous plate, for the electricity of the cover is not derived in the way of charge from the resin, but is the result of the process of inductioe. By substituting the knob of a Leyden jar for the knockle, in order that it may receive a spark after each raising of the cover, the jar may be quickly charged sufficiently to give a powerful shock, or to cause the explosion of a gascous mixture. The electrophorus is sometimes termed the perpetual electrical machine.

ELECTRO-PLATING AND GILDING, the arts by which silver and gold are deposited in thin films upon the baser metals through the agency of electricity. idea of working in the noble metals by electricity was naturally suggested to several experimentalists simultaneously by the beautiful results obtained with copper. (See Electrotype.) The early attempts at copper. (See EBECTROITES.) In carry attempts as electro-plating were, however, somewhat discouraging; for although De la Rive, C. V. Walker, and others, succeeded in obtaining deposits, they could only get deposits of the proper character when they chanced to have in action a power nicely balanced with the work to be performed. The first practical process of electro-plating was introduced by the Messra. Elkington, of Birmingham, who have obtained patent rights for this and many other processes of electro-metallurgy. They employ solutions of the argento-cyanide and the aurocyanide of potassium as electrotypes, from which silver and gold are respectively separated. These compounds are what chemists term double salts; for instance, cyanide of potassium is simply a compound of potassium is silver and cyanogen; but argento-cyanide of potassium is silver and cyanogen combined with potassium and cyanogen, or, what amounts to the same thing, cyanide of silver united with cyanide of potassium. When a solution of this double cyanide is electrolyzed (see ELECTROLYSIS), silver appears at one electrode and

cyanogen at the other, while a proportionate amount of the simple cyanide of potassium is formed in the solution. But if the positive electrode is silver, the cyanogen combines with it and forms cyanide of silver, which unites with the liberated cyanide of potassium, and so keeps up the strength of the solution. In the great electro-plating establishments of Birmingham large oblong vats are used as decomposition-cells: some of these contain from 200 to 250 gallous of the alivering solution. Silver plates, connected with the positive end of the voltaic apparatus, are placed at intervals in the vats: they correspond in extent of surface with the articles to be coated, and face them on both sides. Two brass rods, connected with the negative end of the apparatus, are laid over each vat lengthways, and from these the articles to be coated are Two brass rods, connected with the suspended by copperwires. Almost all the articles which are commonly electro-plated, such as teapots, cruetare commonly electro-plated, such as teapots, cruet-frames, candleaticks, spoons and forks, are formed of nickel silver or German silver, an alloy of copper, zinc, and nickel: this chosen chiefly on account of its silvery whiteness, a quality of great importance when portions of the coating of noble metal have been worn away by use. The articles to be plated are first boiled in a solution of potash, to free them from grease; they are then unickly dinued in red nitrous acid, to remove any then quickly dipped in red nitrous acid, to remove any oxide that may have formed on the surface, and, after this, twice washed in different tanks of water, to remove every trace of the acid. After having been carefully weighed, they are suspended from copper wires and dipped into a solution of mercury in cyanide of potassium, then again twice washed in different tanks of water, and then they are ready for immersion in the silvering solution. Here they are left until the operator has reason to believe that nearly a sufficient amount of silver has been deposited on them, when he removes a test article and weighs it, to ascertain the exact condition of the others, and how much longer they require to remain in the solution. Any thickness of silver may, of course, be given to an article by con-tinuing the operation sufficiently long; but from three to six hours generally suffice to give a proper coating:
1\frac{1}{2} ounce of silver to the square foot of surface is considered to form an excellent plate. In some establishments the silvering solution is kept constantly stirred by simple mechanical arrangements. The silver-plated articles, on being removed from the vats, are well brushed with brushes of very fine brass wire attached to a lathe, and cleaned with fine Calais sand; they are afterwards polished on revolving brushes with rottenatone, then by hand with soft leather and ronge, and lastly with the naked hand. The finishing opera-tion is always performed by women, who, from the greater softness and delicacy of skin, excel men in the art of polishing. Articles with fluted, chased, and ornsmented surfaces, are often burnished after being polished. The burnisher is a piece of highly-polished hardened steel, sometimes of bloodstone, flint, or agate, fitted to a handle; and when judiciously applied agete, fitted to a handle; and when judiciously applied to smooth metallic surfaces, it imparts to them, by friction, an exceedingly brilliant and lasting polish. The process of electro-gilding is nearly the same asthat of silvering, but, of course, plates of gold are suspended in the solution instead of silver plates. Professor Wood, of Springfield, Massachusetts, has communicated the following recipes, which are calculated to be of the greatest service to the electro-metallurgist. The professor observes:—"I believe it is the first time that a solution for plating direct on iron, steel, or Britannia metal has been published. In most of the experiments I have used Smee's battery; but for depositing brass I prefer a battery fitted up as Grove's, positing brass I prefer a battery fitted up as Grore's, using artificial graphite—obtained from the inside of broken coal-gas retorts—in the place of platinum. With one large cell (the zinc cylinder being 8 × 3 inches, and excited with a mixture of one part sulphuric acid and twelve parts water, the graphite being excited by commercial nitric acid) I have plated six gross of polished iron buckles per hour with brass. I have also coated type and stereotype plates with brass and find it more durable than comper brass, and find it more durable than copper facing. To prepare Cyanide of Silver.—1. Dissolve 10 z. of pure silver in 2 oz. of nitric soid and 2 oz. of hot water, after which add a quart of hot water. 2. Dissolve 5 oz. of the cyanide of potassium 747

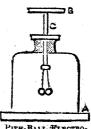

## Electroscopes and Electrometers

in 1 quart of water. To the first preparation add by degrees a small portion of the second preparation, until the whole of the silver is precipitated, which may be known by stirring the mixture and allowing it to settle. Then drop into the clear liquid a very small to settle. Then drop into the clear liquid a very small quantity of the second preparation from the end of a glass rod; if the clear liquid is rendered turbid, it is a proof that the whole of the silver is not separated; if, on the other hand, the liquor is not altered, it is a proof that the silver is separated. The clear liquid is now to be poured off, and the precipitate, which is the cyanide of silver, washed at least four times in hot water. The precipitate may now be dried and bottled for use. To prepare Cyanide of Gold.—Dissolve 1 oz. of fine gold in 1.4 oz. of nitric acid, and 2 oz. of muriatic acid, after it is dissolved, add 1 quart of muriatic acid; after it is dissolved, add 1 quart of hot water, and precipitate with the second preparation, proceeding the same as for the cyanide of silver. To prepare Cyanides of Copper and Zinc.—For copper, dissolve 1 oz. of sulphate of copper in 1 pint of hot water; for zinc, dissolve 1 oz. of the sul-phate of zinc in 1 pint of hot water, and proceed the same as for the cyanide of silver. The electroplater, to insure success in plating upon all metals and metallic alloys, must have two solutions of silver; the first to whiten or fix the silver to such metals as iron, steel, Britannia metal, and German silver; the second to finish the work, as any amount of silver can be deposited in a reguline state from the second solution. First, or Whitening Solution.—Dissolve 2; lb. troy of cyanide of potaseium, 8 oz. of carbonate of sods, and 5 oz. of cyanide of silver in 1 gallon of rain or distilled water. This solution should be used with a compound battery, of three to ten pairs, according to the size of the work to be plated. Second, or Finishing Solution.—Dissolve 4; oz. troy of cyanide of potassium and 10 oz. of cyanide of silver in 1 gallon of rain or distilled water. This solution should be used with one large cell of Smee's battery, observing that the silver plate is placed as and metallic alloys, must have two solutions of silver; solution should be used who one large cell of since a battery, observing that the silver plate is placed as near the surface of the articles to be plated as possible. N.B. By using the first, or whitening solution, you may incure the adhesion of silver to all kinds of brass, may insure the adhesion of silver to all kinds of brass, bronze, red-cock metal, type metal, &c., without the use of mercury, which is so injurious to the human system. To prepare a Solution of Gold.—Dissolve 4 oz. Troys of cyanide of potassium and 1 oz. of cyanide of gold in 1 gallon of rain or distilled water. This solution is to be used warm (about 90° Fahr.) with a battery of at least two cells. Gold can be deposited of various shades to suit the artist, by adding to the solution of gold a small quantity of the cyanides of silver, copper, or zinc, and a few drops of the hydrosulphuret of ammonia.

Electrometers. e-lek-tro-

ELECTROSCOPES AND ELECTROMETERS, e-lek'-tro-scopes, e-lek-trom'-e-ters (Gr. elektron, and skopeo, I see, or metree, I measure), instruments constantly employed in electrical investigations. The distinction hetween the electroscope and the electrometer is often disregarded by scientific writers. Strictly speaking. the former is an instrument for simply rendering electrical excitation apparent by its effects, and the latter an instrument for measuring electrical forces. Any light body delicately suspended may be used as an electroscope. A pith ball hanging by a fine silk thread from a convenient stand is very frequently employed.

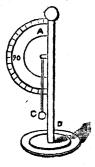

Another form of this instru-

ment consists of two pith balls hung by threads, or very fine metal wires: when excited, the balls diverge in virtue of their mutual repulsion. As the currents of sir render the indications of the pith balls obscure when they are left unprotected, it is found better to enclose them in a glass cy-linder. The annexed woodcut illustrates the arrange-

## Electroscopes and Electrometers

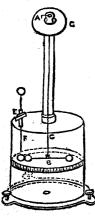

electricity is diffused along the metallic rod C, and reaching the pith balls, they become similarly electrified and repel each other. Bennett's gold-leaf electroscope—a much more delicate instrument, and one of great value in all electrical investigations—consists of two slips of gold-leaf suspended parallel to each sets of two sups of gold-less auspended parallel to each other within a glass receiver, and communicating with a metal cap or disc above. When the cap is touched with an electrified body, the leaves separate, but instantly collapse when a second body charged with the opposite kind of electricity is brought near the cap. The oldest form of the electrometer consists of a vertical conducting-rod with a movable reed arm terminating in a light pith ball, and working over a graduated quadrant or emicircle. The instrument is generally attached to the prime conductor of the electrical machine, and, when charged, the vertical rod repels the reed arm, which rises in the air, and marks on the graduated semicircle This instrument is known as the angle of divergence.

Henley's quadrant electro-meter. Cavendish constructed an excellent electrometer, with two slender reeds terminating with two cork balls, the divergence of which was indicated by a scale. In Coulomb's torsion-balance the force of electrical repulsion is esti-mated by the reactive force of a fine wire suspended vertically, and twisted more or less from its quiescent position. M. Coulomb's most ingeniously contrived instrument consists of a slender bar (B) formed of melted shellac, furnished with a gilt pith ball at one end, and a little vane

HENLET'S ELECTEOMETER.

"This," says Mr. Charles
Brooke, in his edition of
Golding Bird's Natural Philosophy, "is suspended by
a fine metallic wire (0), or still better, by a filament
of spun glass, in the middle of a cylindrical cage of
class. The pupus and of this wire. The upper end of this wire, or glass thread, terminates in a key (D),

COULOMB'S TORSION-BALANCE.

furnished with an index, and capable of moving in the centre of a circle (G), graduated into 360°. Through a hole (E) at the top of the glass cage a rod of lac (F), terminating in a gilt ball, is inserted, being prevented from falling in by a stop at E. This hall is generally termed the carrier ball, on account of its being used to convey the electricity of an excited body to the electrometer, so that its potential may be determined. To use this instrument for measuring the amount of electricity, the rod F is removed, and its ball brought in contact with the substance to be examined. The ball acquires some active electricity, and on being placed in the glass cage it shares its electricity with the ball terminating the horizontal needle B;

## Electrotype

degrees described by the index fixed to the revolving key D gives an approximation to the amount of elec-tricity acquired by the ball F during its contact with the electrified body." Harris's bifilar balance may be the electrified body." Harris's bitilar balance may be regarded as a modification of Coulomb's. A very simple, as well as efficient, form of electroscope is that invented by Dr. Hare, of Philadelphia. A thin strip of gold leaf is suspended within a glass globe. Directly opposite the end of this gold leaf a small brass rod passes through the side of the globe, upon which is a gilt disc of paper or wood. With this instrument both the presence and the kind of elecinstrument both the presence and the kind of electricity may be detected. "In the use of this instrument care must be taken to preserve a dry atmosphere within the glass receiver, which may be, if required, removed from its foot and held over a warm iron. The glass also about the openings through which the brass rods pass should be carefully varnished. With proper care it is quite astonishing how sensitive the instrument becomes to the smallest electrical force. (Harris.) There are many electrometers for esti-(Harris.) There are many electrometers for esti-mating the quantity of accumulated electricity in Leyden jars. Of these the most useful are the dis-charging electrometers of Lane and Cuthhertson, and the unit-measure and quantity-jar of Sir W. S. Harris. For descriptions and figures of all the more im-

portant electroscopes and electronometers, refer to Harris's Rudimentary Electricity.

ELECTROTYPE, e-lek'-tro-tipe (Gr. tupos, an impression), the term commonly applied to the ert of depositing copper and other metals in or upon suitable moulds, through the agency of voltaic electricity, so as to produce faithful copies of coins, medals, statues, engraved blocks, and other works. For this art we are indebted to Professor Jacobi, of St. Petersburg, and Mr. Spencer, of Liverpool, who almost simultaneously invented similar processes for moulding the copper released during the electrolysis of the sulphate, into beautiful or useful forms. The following examples of electrolysis (see this word) will elucidate this important branch of electro-metallurgy. If two platinum plates be connected with the opposite ends of a voltaic battery in action, and be placed in a vessel con-taining water and sulphuric acid, the water will be taining water and sulphurio acid, the water will be electrolyzed, or decomposed by electricity: the hydrogen gas will be released at the plate connected with the negative end of the battery, and the oxygen at that connected with the positive. If into the acid liquid some crystals of sulphate of copper (blue vitriol) be now thrown, electrolysis will still take place, but only one of the elements of the water, namely oxygen, will be evolved; for the hydrogen, on being released from the water, will take the place of the copper in the solution, and the copper thus liberated will be deposited on the negative plate. This experiment may deposited on the negative plate. This experiment may be continued until all the copper is abstracted from the solution. If a copper plate be now substituted for the solution. If a copper plate be now substituted for the platinum one, forming the positive electrode, the water will be decomposed, but neither of the gases will escape. The hydrogen, as before, will take the place of the copper in the solution; the oxygen, instead of appearing at the positive plate, will combine with the copper of which that plate is composed, forming oxide of copper, which will unite with the sulphuric acid to form sulphate of copper. The chemical forces called into action by the current are so heautifully balanced that, in the last experiment, the quantity of copper supplied by the positive plate equals exactly the quantity withdrawn from the solution and deposited on the negative plate. The practice of electrotyping cousists negative plate. The practice of electrotyping consists in preparing models or moulds of objects to be copied, and in so arranging the battery, or apparatus which generates the voltaic current, as to deposit the metal in a compact and solid form upon these models. There are many materials fitted for forming electrotype-moulds; of these, fusible metal, wax, stearine, plaster of Paris, and gutta-peroha, are mostly used. Non-metallic moulds are rubbed over with plumbago or black, bad which is an argulant confluctor of leartingity. The the horizontal needle B; moulds; of these, fasible metal, war, stearine, plaster of Paris, and gutta-percha, are mostly used. Non-metallic moulds are rubbed over with plumbago or black. B necessarily moves, and describes a certain angle, but it retains until it loses its electricity. To measure the amount of energy thus acquired by the balls, the key D, to which the glass thread C is fastened, is turned round, until, by the torsion or twisting of the thread, the ball of B is compelled to some in contact with that of F. Then the number of trotyping is a single cell of a Daniell's battery, alightly

modified. (See BATTERY, VOLTAIC.) In a vessel of stoneware or glass is placed a tube or cell of porous earthenware, and in this a plate or rod of amalgamated zinc. A perforated shelf for holding crystals of sulzino. A periorated shell for holding crystals of sulphate of copper is fixed in the upper part of the outervessel. The prepared mould which represents the copper or negative element of an ordinary voltaic pair is connected by a wire with the zino, and suspended in the outer vessel. To charge the apparatus, the porous cell is filled with a mixture of water and sulphuric acid; the outer vessel with a mixture of water and sulphuric acid; the outer vessel with a saturated solution of sulphate of copper, with a little sulphuric acid in it; and the shelf is well furnished with crystals of sulphute of copper to keep the solution saturated. Certain precautions must be observed in using this apparatus. Thus the mould must not be too small in proportion to the size of the zine; for when this is the case the copper is deposited as a dark powder. Again, it must not be too large, because then the copper is deposited very slowly, and is of a brittle texture. The singleapparatus is now only used for copying medals, seals, and other small works. For electrotyping large objects, or for operating upon a number of small moulds, a separate decomposition cell is used, with a single cell of a Daniell's or a Smee's battery for producing the current. The decomposition cell is filled with a dilute acid solution of sulphate of copper. Two brass rods, connected respectively with the zinc and copper (or platinized silver) of the generating-cell, are laid across the top; to one of these the moulds are attached, and to the other a plate or plates of copper. By a series of chemical changes, to which reference has already been made, the copper from the solution is transferred to the moulds; and the copper plates are dissolved with such regularity, that the strength of the solution is kept up. The useful pur-poses to which the electrotype process is applied are numerable. It is used for copying busts and statues; for manufacturing pipes without seams, boilers, stempars, and other vessels of copper; for reproducing the plates used to print Bank of England notes; for making casts from metal type and woodcuts; to form rollers of copper for printing or embossing calicoes; to give strong coatings of metal to fragile glass vessels, such as chemical retorts and flasks; to prepare metallic lace and cloth; and to cover delicate flowers and minute insects with durable films of copper.—Ref. C. V. Walker's Electrotype Manipulation.

ELECTRUM, e-lek'-trum (Gr. elektron, suber), a term read by the Greeks to depote suber, and supplied by

used by the Greeks to denote amber, and applied by the Romans to this substance and to an alloy of gold and silver containing three or four parts of the former to one of the latter. The metal thus formed was characterized by great lustre and brilliancy. At the pre-sent day the term is often used to denote German

silver.

ELECTUARY, e-lek'-tu-a-re (Lat. eligo, I make choice), in Med., is a form of preparing certain remedies, such means of syrup or honey, so as to be easily taken off a teaspoon or the point of a knife, or without their natu-

rally unpleasant taste being perceived.

ELREMOSYNARY, el-ee-mos'-e-nê-re (Gr. eleemosune, alms), of or belonging to alms or charity. In the early church, the eleemosynamus, or almoner, was a peculiar officer, who received the eleemosynary rents and gifts, and distributed them to pious and charitable uses. In Law, eleemosynary corporations are corporate bodies constituted for the perpetual distribution of the free alms or bounty of the founder of them, to such persons as he has directed. Of this kind are all hospitals for the maintenance of the poor, sick, and impotent, and all colleges, both in our universities and out of them.

all colleges, both in our universities and out of them. ELEGI, ele', jt (Lat. eligo, I choose,—because it is the choice or election of the plaintiff), in Law, is the name of a writ of execution founded on the Statute of Westminster the Second, by which, after a plaintiff or defendant has obtained judgment in an action, the sheriff gives him possession of the lands and tenements of the opposite party, to be occupied and enjoyed until the money due on such judgment is fully paid, and during that period he is tenant by elegit. By the common law, a man could only have satisfaction of the goods, chattels, and present profits of lands, but not possession of the lands themselves. To remedy this,

the above statute was passed, by which not only are the defendant's goods and chattels (except oxen and beasts of the plough) delivered over to the plaintiff, but if there are not sufficient to satisfy the debt, then but in there are not sumctent to satisfy the debt, then the sheriff shall make delivery of a moiety of the de-fendant's land to be held until the whole debt and dumages are paid and satisfied. This statute was altered by 1 & 2 Vict. c. 110, which enables the plaintiff by this writ to seize the whole, instead of only half of the defendant's lands and tenements. Upon this writ the sheriff impanels a jury, who appraise the debtor's goods and lands, and if the former are insufficient to pay the debt, then the latter are also delivered over to the creditor.

ELEGY, el'-e-je (Gr. elegos, from e, and legein, to cry alas!), a term applied, in modern English language, to a short poem composed on a mournful occasion, genea short poem composed on a mournisi occasion, generally on some one's death. Amongst the ancient Greeks, the elegos was a strain of lament, and usually consisted of a poem made up of alternate hexaneter and pentameter verses. The elegiac was also the favourite metre for epigrams. It was used, however, by different poets in different ways. The elegics of Callinus and Tyrtsus are political and warlike; those of Minnermys are contemplative and melancholy: of Mimnermus are contemplative and melancholy; those of Theognis and Solon are moral and political, &c. The first Latin elegiac writer of note was Catullus, and he was followed by Tibulius, Tibutius, and Ovid. The elegiac verses of Catulius are either mournful or satirical, while those of the other poets of the Augustan ers are devoted to subjects connected with successful or unsuccessful love. In more modern times, the poets of nearly every nation have practised this species of composition. Amongst the most successful in this country may be mentioned the Elegies of Hammond, the Lycidas of Milton, and Gray's Elegy.

ELEMENTS, el'-e-ments (Lat. elementum), in Chem .-An element may be defined as a substance which can-not be resolved into others. The ancient philosophers imagined earth, sir, fire, and water to be elements, by the combination of which all other substances were the combination of which all other substances were formed. Modern chemistry has, however, proved that air, earth, and water are compound bodies, and that fire is an effect, and not a substance. The number of substances which cannot be further resolved by chemists are provisionally termed by them elements, it being by no means improbable that many of them are compound hodies. In the present state of knowledge, they are about sixty-five in number, and are divided broadly into the non-metallic and metallic elements. broadly into the non-metallic and metallic elements; these two divisions somewhat running into each other The following is a list of the elements divided in this

manner :-

## Non-metallic Elements.

Name,	Symbol.	Equivalent.
Boron	B	10.9
Bromine	Br	80
Carbon	C	12
Chlorine		
Fluorine		19
Hydrogen		
Iodine		127
Nitrogen		
Oxygen		16
Phosphorus		
Sulphur		
Selenium		
Silicon		
Tellurium		

Dr. William Allen Miller, in the last edition of his valuable "Elements of Chemistry," makes the following general arrangement of the metallic elements:—

I. Alkali Metals-5 in number.

3. Lithium 5. Rubidium 1. Potassium 2. Sodium 4. Cesium

II. Alkaline Earth Metals-3 in number.

1. Barium 2. Strontium 3. Calcium

III. Earth Metals-8 in number.

4. Erbium 7. Lanthanum 1. Aluminium 2. Glucinum 5. Terbium 8. Didymium 3. Yttrium 6. Cerium

## Elements

# IV. Magnesium Metals-3 in number.

#### 1. Magnesium 2. Zino

3. Cadmium

- V. Metals more or less analogous to Iron-6 in number. 1. Cobalt 2. Nickel 3. Uranium 5. Chromium
  - 4. Iron 6. Manganese

## VI. Metale which yield Acids-12 in number.

- 1. Tin 2. Titanium 5. Molybdenum 9. Vanadium
  - 6. Tungsten 10. Arsenicum
- 3. Zirconium
- 7. Niobium
- 4. Thorinum 8. Tantalum
- 11. Antimony 12. Bismuth

## VII. 4 Mctals.

#### 1. Copper 2. Lead 3. Thalliam 4. Indium.

## VIII. Noble Metals-9 in number 1. Mercury

- 4. Platinum 5. Palladium
- 7. Ruthenium
- 2. Silver 6. Rhodium 3. Gold
- 8. Osmium 9. Iridium

The following are only of scientific importance, no use having as yet been found for them. Some of them, such as palladium, rhodium, iridium, and one or two more, would be exceedingly valuable but for their rarity.

Name.	Symbol.	Equivalent.
Cæsium	Св	
Cerium	Се	47
Didymium	D	
Erbium	E	
Glacinum		
Ilmenium (?)	1i	
Iridium		99
Lanthanum	La	
Molybdenum	Мо	46
Niobium (?)	Nb	
Osminm		
Palladium		53·3
Pelopium (?)		
Rhodium		52*2
Rubidium		
Ruthenium		
Tantalum		
Tellarium		61.2
Terbium		•
Thallium		
Thorium		
Titanium		
Yanadium		63.6
Yttrium		
Zirconium	Zr	23.4

ELEMENTS, those numerical quantities, obtained by observation and calculation, which are used in compiling tables that exhibit the ephemeris of a planet's motions. The principal are its greatest, mean, and least distance from the sun; its mean daily motion; its mean annual motion; the eccentricity of its orbit and its inclination to the ecliptic; the longitude of its seconding node and perihelion; and its mass and density.

ELEPHANT, el'-e-f'unt (Elephan).—This is the largest of existing Pachydermata. In ancient times the most curious notions were entertained concerning it, not the least quaint being that it had no joints. Aristotle and Pliny were firm adherents to this doctrine. There can be little doubt that this delusion sprung from the fact that the elephant seldom lies down either in a wild or captive They have been surprised by hunters standing and yet fast asleep. Captain Denman so encountered and shot an elephant. With regard to its disnicination to lie down when domesticated, it is recorded that one belonging to Louis XIV, never assumed any but a standing position during five years. In this case, however, there was evidence that other than natural causes impelled the elephant to remain on his legs; for he was at great pains to scoop in the stone walls for he was at great pains to scoop in the stone walls of his house two deep holes, in which he inserted his tasks before sleeping. Were the elephant's less formed like those of other quadrapeds, the labour of round like those of other quadrapeds, the labour of the this valuable organ. Some time ago one was containing his immense carcass from the ground might in a menageric at Dublin, and by some misformatic formed like those of other quadrapeds.

## Elephant

account for his dislike to a recumbent position; but account for his dislike to a recument position; but his structure is such that lying down and rising are matters of but little difficulty. Instead of bringing his hind legs under him when he lies down, he extends them behind him, in the position of a kneeling human being; when he wishes to rise, he simply draws his hind feet gradually under him, and his enormous weight is levered up with perfect case. This mobility of limb is of west service to the slenbart in the nerform of limb is of vast service to the elephant in the performance of his duty as a beast of burden; and with a howdah on his back containing eight or ten persons, and the driver on his neck, he can descend steep hills with perfect safety. He manages in this way: kneeling down at the commencement of the declivity, he puts out one fore-leg and feels cautiously for a safe foot-ing; if he does not find it, he hanners at the soft soil with his heavy foot until he has made an indentation sufficient to secure firm footing. One foot thus accommodated, the other is drawn out with equal care, and provided for in the same manner as the first. Then one of the hind legs is cautiously drawn forward and one of the first feet being released from the foothole, it is inserted in its place: and all this is performed so rapidly that it might be repeated at least three times in as little time as it takes to write this explanation. It is almost needless to observe that the elephant is distinguished by the possession of a long

ELEPHANT.

trunk or probosus, which serves him in place of a hand, and enables him to perform many extraordinary Without this carious appendage he would find feats. Without this curious appeniage he would mut existence difficult, if not impossible. Elephants some-times go blind while in a state of freedom, but, guided by this exquisite organ of touch, they are still en-abled to make their way through dense forests, to gather food, and to avoid ditches and hollows. The elephant's trunk is not composed of a mere series of muscular rings, as its appearance would lead one to suspect. It has three perfect and distinct uses. As an organ of smell, it is an elongated and curiously clastic nose. Within it two canals are continued from the nostrils, which are reflected round the nasal bones and then proceed straight to its end. These canals are separated by, and embedded in, a fatty elastic membrane containing thousands of minute muscles. Of these there are threesets,—an outer longitudinal, com-posed of four layers; an oblique set, which are variously directed; and a third set, which radiate from the tubes to the circumference. They are very small, and supposed to number as many as forty or fifty thou-sand. Besides as an organ of smell, the elephant's trunk serves as a sucker, by which the great animal may quench his thirst at the shallowest pools. There is no passage from the trunk to the mouth; but the former may be filled, and then, the mouth of it being

gradually from the shoulder to the middle, and thence descending to the insertion of the tail; all his joints firm and strong." It is conjectured that elephants attain their full growth at about their twentieth year. Their size has been greatly exaggerated. In for times it was thought a common thing for the elephant times it was thought a common thing for the captains.

to reach a height of twenty feet; but it is now pretty certain that ten feet is tail, and twelve feet an extraordinary height for one of these animals. Among the Singhalese the belief is still prevalent that the elephant attains the age of two or even three hundred years; it, however, is a tolerably well-ascertained fact that the duration of life in these animals is from seventy to eighty years. There are records of the elephant tiving to a greater age than this. Amongst the papers of Colonel Robertson (son of the historian of Charles V.), who held a command in Ceylon in 1799, shortly after the capture of the island by the British, showing that a decoy was then attached to the elephant establishments at Maturs, which the records proved to have served under the Dutch during the entire period of the occupation (extending to upwards of 140 years), and was said to have been found in the stables by the Dutch, on the expulsion of the Portuguese in 1656. The number of elephant tasks brought to England is very large. In Sheffield alone it is stated that upwards of 46,000 tasks are annually consumed. The workers in ivory in that town are above 500 in number, and the value of the ivory about £30,000 per annum. It may be worth while here to remark that the well-known Indian-yellow, or Purree, is held to be a commendant

the earthy phosphate and urea deposited from the urine of the elephant.—Ref. Wild Sports of the World. RLEPHANTIASIS, OF BARBADOES LEG, el-e-fan-ti-d-sis (Gr., from elephas, an elephant), is the name of a discase common in the East and West Indies, and so called from the skin of the afflicted limb becoming rough, scaly, and enormously thickened, so as to re-semble the leg of an elephant. It generally comes on with great heat of the skin, alternating with profuse perspiration and ardent thirst. The part becomes red, herspiration and ardent thirst. The part becomes red, hot, swelled, and painful, increases to great size, and becomes a burden to the patient. Though it is the leg that is generally affected by this disorder, other parts of the body are liable to its attack; but it is not usual for more than one part to be morbidly enlarged in the same individual. In the treatment of this disease of its earlier stages the use of laxatives and disphoretise recommended, together with the application in iodine ointment to the part, and firm bandaging.

Indian-yellow, or Purree, is held to be a compound of

ELEUSINIAN MYSTRIBS, el-su-sin'-e-in mis'-ter-ees, a term applied by the ancient Greeks to the festival and sacred rites originally celebrated only at Athens and Eleusis, in honour of the goddess Ceres. It was considered the holiest and most venerable of all the festivals of Greece. There are several traditions current as to its origin; and many of the mysteries are unknown, as they were so superstitiously observed, that any person who revealed any of the religious cere-monies was put to death. The first Eleusinan festivals are generally attributed to a tradition that Geres, or Demeter, as she was called by the Greeks, while seek-ing for her lost daughter Persephone, overwhelmed with grief and fatigue, rested upon a stone called "the sorrowful stone," near a well at Eleusis. Round this well the Eleusinian women first sang their choruses, and instituted the first mysterious rites. In after-time the festival was divided into two classes,—the greater and lesser mysteries. The latter was considered a preparation for the former, and was held at Agræ, on the Ilissus. The celebration at Eleusis commenced in the third month of the Attic year, and lasted about nine days. The initiated were called epoptai or ephuroi. On the first day those who had been initiated in the was called aguris, 'an assembly.' A large number of etrangers also crowded to Athens at the same time. On the second day the initiated purified themselves by ablations; hence it was called alade mysta,—' to the sea, ye initiated!' Very little is known with certainty about the proceedings on the third day. It seems to have been held as a day of fasting, a frugal meal of cakes made of serame and honey being taken in the evening. Sacrifices were

it was found almost to a depth of two feet into the hard floor of the den. The dentition of the elephant is of a very remarkable nature. From the upper jaw extend very remarkable nature. From the upper jaw extend two enormous teeth fixed in sockets in the front of the mouth, but which, in fact, are neither increors nor tusks, although by the latter term they are generally known. They spring, however, from the intermaxillary bones, and must be regarded as the representatives of the incisors. They grow from a permanent pulp, and continue to increase in size during the life of the animal. The incisors are wanting in the lower jaw, as are also the canines in both jaws; and the only other teeth possessed by this immense quadru-ped consist of two molars of a most remarkable structure on each side of each jaw. These teeth are of a very large size, and a quadrangular form. They consist of a series of plates of the ordinary substance of teeth (dentine), each coated with a layer of enamel, and united together into a mass by a material called the coment. The form of these transverse plates of dentine and enamel varies greatly in the different species. The formation of the molar teeth, like that species. The formation of the moint recent, and con-of the tasks, is going on as long as the elephant lives; but with this difference, that whilst after shedding the first or milk tusks, the pulp of each tusk continues adding matter to its base without any change, in the case of the molars it is a succession of separate teeth that is produced, the hindermost pressing gradually forward to take the place of those which have been abraded by use, and cast off as unserviceable. The period of ges-tation of the elephant is a few days over twenty months. The breasts of the female are placed under the chest, and the young one sucks not with the trunk but with the mouth. The strongest proof of the elephant's antipathy to a recumbent position may be drawn from the fact that although the new-born calf is much too short to reach the test, the mother, rather than lie down, will extend her legs so as to bring her breast nearer the earth. In a state of domesticity, the elephant-keeper will, under such circumstances, build a little platform of earth for the elephant-calf to stand on while it sucks. At its birth, the calf is about thirty-six inches in height. Weaning a young olephant is, by all accounts, a formidable undertaking. A colebrated English traveller thus describes the business :-"About two-and-thirty females with their young ones were driven into the inclosure, and shortly afterwards there also went in four great male clephants, the riders of which had in their hand a long rope with a noose in the end. After many unsuccessful attempts, they succeeded in snaring one of the calves by the hind This was a difficult matter to accomplish, for, leg. This was a difficult matter to accompann, 101, besides its own opposition, it was protected by the adroitness of several of the grown females, who crowded round it. So outrageously did the calf struggle, that the big males had frequently to beat him, and I observed that once or twice they lifted him with their trunks literally off his legs." There are two living species of the genus Elephas,—the Indian (Indiaus) and the African (Africanus). The latter is confined to the southern (Africanns). The latter is commed to the southern parts of Africa, and is distinguished from the former by the convexity of its forehead, the enormous size of its ears, and the lozenge-shaped arrangement of the dentine and ivory in its molar teeth. The Indian or Asiatic elephant has the forehead concave, the ears of moderate size, and the dentine and enamel of the teeth arranged in transverse hands. It differs likewise from the African species by the paler brown of the skin, and in having four nails on the hind feet, instead of three; and its tusks are smaller, although in size and weight the Indian elephant exceeds the other. The largest tusk on record is spoken of by Kloknes as having been sold at Amsterdam: its weight was 350 lbs. According to a celebrated elephant-dealer, an animal's "points" should appear as follows:—"Ears large and rounded, not ragged and indented at the margin; eyes dark hazel, and free from specks; roof of the mouth and tongue without dark or black spots of any censiderable size; trunk large; tail long, with a tuft of hair reaching the special on each forcefort, and nearly to the ground; five mils on each fore-foot, and nearly to the ground; are issue on each fore-root, and sand honey being taken in the overnigt. Satrimete were four on each of the hind ones; head well set on, and also offered up, principally consisting of sea-fish and carried rather high; arch or curve of the back rising barley cakes. The fourth day was devoted to a pro-

cession, with a basket containing pomegranates and poppy-seeds. It was carried on a waggon drawn by oxen, which women followed, bearing in their hands mystic cases, while the spectators shouted, "Hail Ceres!" as the procession passed. The fifth day was mystic cases, while the spectators shouted, "Hail Ceres!" as the procession passed. The fifth day was called the Day of the Torches. The initiated went by torchilght on the evening of this day to the temple of Ceres at Eleusis, where they seem to have remained. This custom is supposed to have been symbolical of Ceres wandering in search of her shaughter. The sixth, Iakchos, in honour of Iscohus, the son of Ceres. The statue of Iscohus, adorued with a garland of mystle, and bearing a torch his hand, was carried along the Sacred Road, amid shouts of joy and songs, from the Ceramicus to Eleusis. Great numbers of persons accompanied this procession. On the night between the sixth and seventh procession. On the night between the sixth and seventh days, the initiated remained at Eleusis, and those who were neither mustai (initiated in the lesser mysteries) nor epoptai were sent away by a herald, and the last mysteries were begun. The mustai repeated the oath of secrecy which they had sworn at the lesser mysteries, underwent a new purification, and were led by the mystagogues, in the darkness of night, into the lighted interior of the sanctuary, and were allowed to see what none but the epoptai ever beheld. The later writers none but the epoptal ever pencia. The later writers speak of the rites connected with the oath as being of an awful and horrible character. This probably arose an awill and horrible character. This probably arose from ignorance, as the earlier writers mention nothing of the kind. On the seventh day the initiated returned to Athens with great mirth, and amid great raillery and jests from the spectators, especially at the bridge over the Cephisus. The eighth day was called Epidauria, and was a kind of additional, for these who he some aggident had some teacher. those who, by some accident, had come too late or had been prevented from being initiated on the sixth day. On the ninth day, the principal ceremony consisted in the filling of two earthen vessels with water or wine: the contents of one were then thrown to the east, and those of the other to the west, while the priests who performed the libation uttered mystical Every free-born Athenian was compelled to be initiated into the Elcusinian mysteries. Slaves, prostitutes, and those who had forfeited their citizenship, were excluded. During the time of the celebration of the mysteries, no one taking part in the ceremonies could be arrested, either for debt or for any offence. The chief priest was called the Hierophant, and the second dignitary the Daduchus, or torchbearer. The Eleusinian mysteries survived the independence of Greece for a long time. Attempts were made under the emperor Valentinian to suppress them, but unsuccessfully: they appear to have continued to the time of the elder Theodosius.

ELEVATION, el-e-vai'-shun (Lat. e, and levo, I raise), in the ceremony of the Mass, is the raising, first, of the not, and then of the cup, to receive the homage of the people as the body and blood of Jesus Christ,—the priest himself previously performing the act of adoration by a deep genuflection. At the elevation a bell is rung for the people to look upon the host. This ceremony was introduced into the Latin church in the beginning of the 12th century.

ELEVATION, in Arch., the view or perspective of a building. The term is also applied in architectural drawing to the front view of a building or object drawn

arswing to the front view of a building or object drawn to a scale without regard to perspective.

ELEVATOR el-e-vai'-tor (Lat.), in Anat., is a term applied to various muscles of the body, whose action is to lift up or elevate the parts to which they are attached; as the elevator muscles of the eye, mouth, &c. It is also the name given to an instrument in surgery, employed for raising depressed portions of the bones of the skull.

ELP. (See Fairles)

ELF-ARROWS, elf -ar-roze, a name popularly given in this country to the flint arrow-heads that are occasionally found, and which were at one time used here as weapons of attack, as they still are among various savage tribes. The popular belief was, that they were shot by elves or fairies; and, as they were most commonly met with after showers of rain, they received in Germany the name of thunderbolts. They were regarded as a preservative against witcheraft and poison, and were hance frequently worn about the person.

They are now commonly to be seen in museums of antiquity.

RLGIR MARBLES, el'-jin, a collection of pieces of soulpture, made by Thomas, earl of Elgin, between the years 1802 and 1812, when he filled the office of am-bassador to the Ottoman Porte. The vessel which was conveying the marbles to this country was wrecked near Cerigo: they were, however, recovered from the sea, and ultimately purchased by the British government for the sum of £35,000. They are now to be seen in the British Museum, in what are termed the Eigin rooms. The collection consists chiefly of slabs and fragments from the ruins of the Parthenon, a temple sacred to Minerva, built on the Acropolis of Athens during the time of Pericles, in the 5th century before Christ, and adorned with magnificent friezes and groups of sculpture, executed under the direction of Phidiss.
The sculptures are of three different kinds:—metopes, or rectangular slabs that covered the spaces between the triglyphs of the Doric frieze of the peristyle on the southern side of the building; parts of the frieze that surrounded the exterior of the entire temple, at a height of 40 feet from the ground, forming a continu-ous series of sculpture about 520 feet in length and 40 inches in height; and portions of statues that adorned the pediment, which are unfortunately con-siderably mutilated, being for the most part without heads, arms, or feet. The metopes are executed in high relief, and represent the battles of the Centaurs and Lapithæ: the slabs are sixteen in number, one, how-ever, being a cast in plaster from the original piece, or rectangular slabs that covered the spaces between ever, being a cast in plaster from the original piece, which is now in the Louvre at Paris. The frieze is in low relief, and represents the procession that took place at Athens once in five years, called the Pana-thenæa. There are about 325 feet of this frieze at the British Museum, 250 feet being portions of the original marbles, and the remainder consisting of plaster casts. Of the statues, the best are the group known as the Fates, the statue of Theseus, the torse of Ilissus, and the spirited head of one of the horses of Night. There the spirited ness of one of the norses of right, are the remains of great beauty in the collection; among which may be mentioned the statue from the monument of Thrasyllus, the Carystid from the Pandrosion, and the column from the Erechtheum, with some urns and sepulchral inscriptions.-Ref. English

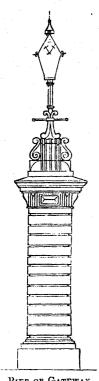

some urns and sepulchrai inscriptions.—Ref. English Cyclopadia—Arts and Sciences.

ELISION, e-lizh'un (Lat. elizio, from elido, I strike off), in Gram., is the cutting off or suppressing a vowel or syllable, particularly at the end of a word, for the sake of cuphony, or in poetry to suit the verse. Elision occurs chiefly in the ancient languages of Greece and Rome.

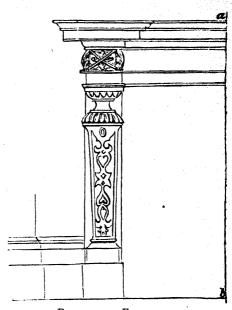

ELIXIR, e-liks'-er (Lat. elixo, I extract by boiling), is a name given to various medical preparations, consisting of wine, or spirits of wine, and various aromatic and bitter vegetable substances. The word has now almost gone out of use, and its place is supplied by tincture. Strictly speaking, however, clixirs differ from tinctures in being thicker and more opaque, and containing less spirit.

CONTAINING ICES SPIPIL.

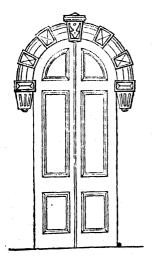

ELIZABETHAN ARCHITECTURR, e-liz-ü-be'-thun, the style that prevailed in England during the latter part of the 16th century and the early part of the 17th, and so called because it is the characteristic style of buildings erected during the reign of Elizabeth. It was used only for palaces, mansions, and dwelling-houses, being unsuited for ecclesiastical architecture; but, for the purposes to which it was applied, it was stately and picturesque as far as the exterior is con-cerned, and afforded the means of obtaining a commodious and comfortable interior. It is somewhat similar to the Renaissance style of architecture in France, and is sometimes said to consist of a combination of this is sometimes said to consist of a combination of this with the Tudor style that prevailed in the reigns of Henry VII. and Henry VIII. The finest old country mansions and palatial residences in England are in this style, and among the best may be mentioned those of Longleat; Holland House, Kensington; Burleigh; Wollaton House, Notts; and Aston House, wear Birmingham, which has lately been purchased and converted into a museum. The most common form of the ground-plan of houses in this style is that of of the ground-plan of houses in this style is that of the letter B, and it is supposed that it was adopted as a compliment to Queen Elizabeth, as it was the initial letter of her name: it is most probable, how-

ELIZABETHAN DOORWAY.

ever, that the plan was chosen on account of the convenience it offers for the peculiar structure of the venience it offers for the peculiar structure of the exterior and the interior arrangements, and that the compliment was an after-thought. The main part of the mansion is represented by the back of the letter, while the wings at the sides and the porch in the centre are denoted by the three parallel lines projecting from it at right angles. The material most company that the declaration is the contract of the c ing from it at right angles. The material most com-monly used was brick of a bright red colour; the quoins and dressings of the windows were occasionally of freestone; the face of the exterior was also frequently ornamented by dark bricks disposed so as to form a diamond-pattern, in diagonal lines cutting each other at right angles. When stone was used, it was generally covered with stucco, and the exterior was painted. The larger buildings were reared on a solid basement, and the entrance was gained by flights of steps leading to a terrace with a balustrade in front. The windows were square-headed, generally broader than they are high, and divided into compartments by mullions and The different floors were divided on the transoms. exterior by broad string-courses running along the en-tire front of the building, and elaborately ornamented with arabesque scroll-work, consisting of curved and angular bands, and bosses combined in patterns of endless variety. The spaces between the windows were adorned with pilasters on pedestals, which were panelled and ornamented with scroll-work. The pilasters were always surmounted by a continuous entablature, and the space between the entablature of one set and the base of the one above it is occupied by the ornamented band or string-course already mentioned. The gables were various in form, the ogee gable being the most common: the greater part of them are adorned with arabesque scrolls and mouldings. The chimney-shafts were tall, and generally circular, octagonal, or twisted in shape; sometimes they were banded with interlaced fretwork. The broad and stately staircase of polished oak is one of the most striking features of the interior, the balustrades and massive uprights at the angles being richly carved. The ceilings were divided into compartments by rectangular and curved mouldings. The walls were panelled with wainscot, which had the effect of rendering the rooms dark, and to a certain extent gloomy. The chimney-pieces were claborately adorned, and were lofty and massive. were ensurance, and were only and massive. One of the most characteristic examples of Elizabethan architecture is that afforded by Wollaton House, in Nottinghamshire. To gain a suitable and comprehensive idea of the picturesque beauty of mansions in this style, both externally and internally, we have only to turn to some of the charming drawings of Louis

to turn to some of the charming drawings of Louis Haghe and the coloured illustrations included in Knight's Old England. At fig. 2, Plate XLVIII., is shown an example of a window (with plan) in the Elizabethan style; and upon the preceding page are given other examples of the same style.

RLK, or MOOSE DEER, elk (Sax. elch), (Alces Malchis), the largest of all the deer tribe, and common to the northern parts of both hemispheres. The antlers of this animal are comparatively short, but broadly dilated, and terminated by a numerous series of long points. When fully grown, these organs weigh from fifty to sixty pounds. The moose does not reach its full development till its fourteenth year, and then may full development till its fourteenth year, and then may be met measuring six or even seven feet at the shoul ders. Its legs are very long; its neck thick and short; its head elongated, and terminated by a broad The coat of the moose is composed of long bristly hair, of a light ash-colour, and of a dark russet-brown on the surface. In the winter the coat of the bull moose changes to a glossy black. From behind the ears down the neck and part of the back extends a mane, barah and thick, and nearly a foot in length. The hair on the belly and inside the legs is sandy colour. Pendent from the spot where the junction of the head and neck occurs is a baggy pouch covered with long black hair, and known as the "bell." The food of the moose consists during the summer months of such leaves and tender branches as abound in its native forests. In the winter season it subsists on the tops of young shoots, pulling them into its mouth by its grehensile upper lip (or mouffle), and biting them off. When pressed by hunger, however, it will eat any green thing it meets, except the foliage of the apruce-

754

tree; that, according to recent observations, it never touches. It readily eats grass, which, unless rising very tall, or growing on a bank, it cannot, from its stiff very tall, or growing on a bank, it cannot, from its stiff and short neck, orop without straddling awkwardly. Its flesh is highly esteemed as an article of food, especially when smoked or dried bacon-fashion. The "mouffle" is the most choice bit, and is said to be, when boiled, rich and gelatinous, and to resemble the renowned green fat of the turtle. "As the flesh of the elk is palatable, and the horns and skin extremely useful, the animal is much persecuted by hunters. It is a swift and enduring animal although the geit is is a swift and enduring animal, although its gait is clumsy and awkward in the extreme. The only pace of the elk is a long swinging trot; but its legs are so long and its paces so considerable, that its speed is much greater than it appears to be. Obstacles that are almost impassable to a horse are passed over easily by the elk, which has been known to trot uninterruptedly over a number of fallen tree-trunks, some of them five feet in oircumference. When the ground is hard, and will bear the weight of so large an animal, the hunters are led a very long and severe chase before they come up with their prey; but when the snow lies soft and thick on the ground, the creature soon succumbs to its lighter antagonists, who invest themselves in snow-shoes, and soud over the soft snow with a speed that shoes, and soud over the soft enow with a speed that speedily overcomes that of the poor elk, which sinks floundering into the deep snow-drifts at every step, and is soon worn out by its useless efforts."—(Wood's Natural History.) The most successful way of hunting the moose is by "calling;" that is, imitating the trumpeting noise made by the female at the pairing season to attract the bull. Something like "quoh quorh" is the sound, and, by means of a tube of birch lark the skilful huntary is any light to simulate it executive. bark, the skilful hunter is enabled to simulate it exactly. Shy as the gazelle at other times, the bull moose swiftly obeys the invitation, and is thus brought within range of the rifle of the hunter, who is concealed in the thicket.

ELL, et (Ang.-Sax.), a measure of length in various countries, used principally for cloth, linen, silks, and similar fabrics. Formerly it was much used in England; but it is now almost entirely superseded by the imperial yard. An English oll is 45 inches, or 5 quarters; a Flemish ell is 27 inches, or 3 quarters; the French ell is 6 quarters, and the Scotch ell 37 25 Eng-

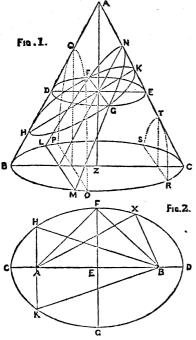

ELLAGIC ACID, el-lai'-jik, an insoluble acid found as a grey crystalline powder during the preparation of gallic acid from gall-nuts. It also occurs, curiously enough, in the intestinal concretions called bezoar-stones, found in the stomachs of the wild goats, antelopes, and deer of central Asia. M. Braconnot, who made a particular study of the substance in 1818, gave it the name of ellagic acid, which he formed by reversing

the word galle (Fr., gall).

ELLIPSE, el-lips' (ir. elleipsis), an oval curve, one of the comic sections. (See Contr. Sections.) The sections of a cone formed by a plane pussing through it et right angles to its axis is a circle. If the plane cuts the cone in a direction parallel to its surface, the conic section so formed is a parabola; but any section formed by the passage of a plane through the cone at formed by the passage of a plane through the cone at any angle to its axis between a right angle and the angle at which the surface of the cone is inclined to the base, is an ellipse. To make this clear, let the figure A B C represent a cone (see Cons); any section of this cone at right angles to the axis A Z, or parallel to the base, as the section D F E G, will be seen at once to be a circle. Let the plane passing through the cone in the section D F E G be now supposed to revolve shout F G, a diameter of the circle D F E G, as about an axis, any section of the cone, as H F K G, made in its revolution from its original position when it was at right angles to the axis, until it assumes a position L F N G M, parallel to the surface of the cone, as an ellipse. The section of the cone formed by the position LFNG M, parallel to the surface of the cone, as an ellipse. The section of the cone formed by the last-named position of the plane is a parabola. When the outting-plane is in a direction parallel to the axis, as OQP or RTS, the curve thus formed is an hyperbola. In fig. 2, CFDG represents a perfect ellipse, The points A and B are called its fooi. CD its greater axis, and FG its lesser axis. C is its centre, and the fraction represented by EB as the numerator, and ED as the denominator, its eccentricity. The lines drawn from any point in the circumserence to the foci are

### Ellipsia

termed the focal distances of that point, and the sum of these is the same for every point in the circum-ference, since the curve is generated by the revolution of a point controlled by a cord, equal in length to the

THE ELLIPSE.

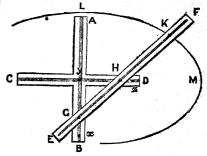

greater axis CD, and fastened at the ends to the foci AB; thus, AC+CB=AH+HB=AF+FB=AX+XB, &c. The line drawn through either of the foci parallel to the lesser axis, as H K, is called the latus rectum of the ellipse.

ELLIPSIS, el-lip'-sis (Gr. elleipsis, an omiconom), and Gram, and Rhet., is the omission of one or more words which may be easily supplied by the imagination. It is used either to express passion or for the sake of brevity and conciseness.

RULIFFIC COMPASS, el·lip'-tik, the name applied to any contrivance used for describing an ellipse. The most common and simple method is to take a string, equal in length to the major axis of the ellipse (see ELLIPSE), and attach the ends to two pins, which are stuck into the material on which the ellipse is to be stuck into the material on which the ellipse is to be described, at those points in the major axis which represent the foci of the ellipse. The string must be then extended on the point of a pencil, and the curve traced by the point, the string being kept at full stretch, will be an ellipse. Another plau is to take two pieces of wood or metal, which may be fired at right angles to each other: a deep groove is cut in the upper surface of each in which two pins travel which are angles to each other: a deep groove is cut in the upper surface of each, in which two pins travel, which are attached to a beam, with a hole or socket at one end of it for the reception of a pencil. The pins may be fixed at any distance from each other on the beam, by means of clamping screws, so that ellipses of various sizes may be described, as large as the length of the beam will allow. The operation may be understood from the accompanying figure. A B C D are the grooved pieces at right angles to each other, EF the beam, GH the pins, K the pancil point. Now, in describing the curve LM, a quarter of the ellipse, when the pencil is at L the beam is exactly on the top of A B, lying along its surface and in the same direc-

## Elysium

tion with it; the pins are at  $\varphi$  and y. As the pencil traces out the curved line, the pin at x moves along the groove into the position y, while that which was at y moves to z; so that, when a fourth of the ellipse has

ELLIPTIC COMPASS.

been described, the beam is exactly on top of C D, and in that direction. The pine travel up and down the grooves from either end to the centre, and from the centre to either end, until the entire curve has been traced out.

ELM. (See ULMUS.)
ELMO'S FIRE, SAINT, el'-moze, a luminous appearance or flery meteor frequently seen playing about the masts and rigging of vessels at sea, during dark stormy nights. The phenomenon is due to atmospheric electricity.

tricity.

ELOCUTION, el-o-kw'-skun (Lat. e, and loquor, I spenk), is delivery, or the art of effective speaking. (See Delivery, Orazony.)

ELOGE, ai-lozhe' (Fr.; Lat. elogiv., Gr. eulogia), denotes, literally, praise, and is more particularly splied to orations delivered in bonour of a deceased person. When a member of the French Academy dies it is the queton for bis successor to deliver dies, it is the custom for his successor to deliver a panegrical oration, setting forth his labours and merits. These cloges are generally printed and published, and some of them form cloquent and valuable contributions to literature.

ELONGATION, e-lon-gui'-shun (from low Lat. elongo, I lengthen).—In Astron., this name is sometimes applied to the angular distance between the sun and any other heavenly body, viewed from the earth's surface. not used to express the distance between any two stars.

ELOPEMENT, e-lope'-ment (Du., from loopen, to run), in Law, is where a married woman of her own accord leaves her husband and goes to live with an adulterer. By the Statute of Westminster the Second, if a woman voluntarily leaves her husband and lives with an adulterer, she shall lose her dower, unless her hus-band be voluntarily reconciled to her.

ELUTRIATION, e-lu-tre-ai'-shu o-lu-tre-ai'-shun (Lat. elutrio, cleanse), in Chem., a process employed for separating substances reduced to powder, when of different specific gravities, by means of water. It is much employed in separating metals from their ores. Gold-

employed in separating metals from their ores. Goldwashing is a rough elutriation.

ELYES. (See FAIRIES.)

ELYESUM, or ELYELA FIRLDS, e-lizh'-e-um (Gr. elusion), in Myth., a place or island in the infernal regions where the souls of the virtuous were supposed to dwell after death. There happiness was perfect, and the pleasures innocent and refined. The air was wholesome, serene, and temperate. The employment of the some, serene, and temperate. The employment of the spirits of heroes differs according to different poets. Homer, in the "Odyssey," describes such a region as that mentioned above, while in the "Iliad" Achilles in Elysium is depicted as in a sombre place, envying the meanest person on earth. Nearly all the later classical poets describe Elysium as a place of light and happiness, some adding continual feasing and revelry, others in warlike sports, and others in taming horses and hystics. and hunting. The position of the Elysian fields differe also according to vasious poets. By some it is said to be in mid-air, others in the sun, others in the moon,

and others in the centre of the earth, near Tartarus: the general belief was that they lay in one of the isles of the ocean, called the Fortunate Islands, now called the Canary Islands.

EZZEVIE EDITIONS, el'-ze-ver.—The Elzevirs were a family of celebrated printers and publishers at Amsterdam, Leyden, the Hague, and Utrecht, who flourished mostly in the early half of the 17th century, and who gave to the world many beautiful editions of the best authors of antiquity. The Elzevir editions have been long and deservedly esteemed for the clearness, delicacy, and perfect equality of the characters, for their close position together on a solid and very white paper, and the excellence of the press-work. Their Virgil, Terence, and Greek New Testament, are regarded as their masterpieces. The Elzevirs published several catalogues of their editions, and a list of them is given by Mr. Horne in his "Introduction to the Study of Bibliography;" but the best account of

ished several catalogues of their editions, and a list of them is given by Mr. Horne in his "Introduction to the Study of Bibliography;" but the best account of them is to be found in the fifth volume of Brunet's "Manuel du Libraire." pp. 799—827.

EMANATION, em-à-nai-shun (Lat. emanare, to emanate, issue, or flow out), in the ancient systems of philosophy, is applied to that doctrine which regards all created things as emanations from the Supreme Being. In this view there was no spontaneous creation; but all things issued necessarily out of the Divine fulness. This doctrine came from the East, and exerted a powerful induence on the systems of ancient Greece, particularly the Pythagorean. Traces of it are also to be found in the Hindoo mythology of the present day. In theology, the doctrine of emanation has been employed to explain the relationship among the persons of the Trinity, the Son and Holy Ghost being regarded as

effluxes or emanations from the Father.

EMANCIPATION. (See SLAVERY.)
EMANCIPATION, ROMAN CATHOLIC. (See ROMAN
CATHOLIC EMANCIPATION.)

EMBLEMING, embau\*-ing (from Fr. embaumer), is the art of preserving the body after death, from decay, by means of aromatics, antisoptics, or desiccation. The embalming of the dead was practised by the ancient Egyptians from the earliest times, and was associated with their religious belief, for they held that the soul, after completing its cycle of separate existence of several thousand years, again returned to the body, and if found decayed or wasted, it transmigrated. The invention of the art was ascribed to Anubis, the son of Osizis, who first performed this office to his father; and hence all deceased persons were supposed to be embalmed after the model of Osiris. Herodotus and Diodorus have left us accounts of the process of embalming in their time; but these differ in several respects from the appearance of the mummies of the present day. The body was first delivered to the undertakers, called by the Greeks paraxhists or "flank-incisors," a low and polluted class of persons, who resided in the cemeteries or suburbs. A scribe first marked with a reed pen on the left side below the ribs a line, along which the paraschistes made a deep incision with a rude knife of stone or flint, on which he was immediately pursued with stones and imprecations by the bystanders, as if he had committed some beinous offence. The taricheutes, or preparer, then proceeded to remove the entrails and lungs, with the exception of the heart and kidneys. The brains were drawn out through the nostrils by a crooked iron instrument. The entrails were washed with wine of palms and perfumed, and the cavities were then filled up with myrrh, cassis, and other aromatic drugs. The flank incision was then sewed up, and the body steeped in an upright position either in a sepulcher or in one of their own spartments, for many of them kept their dead at home, esteeming it a great comfort to have the bodies of their relatives beside them; and some times they were produced at festive entertainments. This was the most expensive mode of embalming, and

seventy days: after which the viscers came sway, and nothing remained but the skin and bones. The third method, used only for the lower classes, was performed by washing the body with myrrh and laying it in salt for sevency days. All classes among the Egyptians were embalmed, even the malefactors; and we read in Scripture that the body of the patriarch Jacob was practised by the ancient Egyptians, is attested by the numerous mummies that are to be seen in the present day in all the great museums of Europe. (See Mumarx.) Various other nations of antiquity adopted certain means for the preservation of the human body. The Persians employed wax, the Assyrians honey; the Jews embalmed some of their kings with spices, with which the body of our Lord was also anointed, and Alexander the Great was embalmed with wax and honey. The only people, however, who adopted an elaborate process like the ancient Egyptians are the Guanches, or ancient inhabitants of the Canary Isles.

EMBANEMENT, em-l-dink'-ment, a term used in engineering, both civil and military: in the former it is applied to a mound of earth broad at the base and narrow at the top, thrown up to form a roadway or canal at a level above that of the ground, or to protest ground that lies low from being inundated by the sea ar any river. In Mill, it is generally applied to the mass of earth thrown up against the revertments of a rampart or any scarped work, or which is raised in the form of a bank to furnish any earthwork for defensive purposes. It should be the especial care of the engineer to see that his embankments are constructed on ground which affords a firm and unyielding basis, or, if the ground below he loose and compressible, a proper foundation must be secured by driving piles, or by making pits in the soft ground, which must be filled with stones and other materials that do not readily yield to pressure. A good foundation secures the work from displacement by vertical compression, and care must be taken to avoid lateral dis-placement by cutting deep trenches at the foot of the slopes to carry off any excess of moisture. The slope of the embankment must also be regulated by the nature of the soil used in its construction, to prevent masses of earth from slipping away from the sides, which will happen, particularly after a heavy fall of rain which has continued for some time, if the sides be too steep. For chalk, gravel, rubble, and loamy soil, the base of the slope should be to the height as 14 to 1; for sand and ordinary clay soils it should be as 2 to 1; and for mari and greasy soils as much as 3 to 1. The nature of embankments best suited to 3 to 1. The nature of embankments been suited to resist water, and the method of constructing them, will be found elsewhere, as well as the formation of those constructed for the sides of canals. (See Canal, Sea Dugmences, River Defuncts) Embankment for roads and railroads are formed by depositing the material obtained from excavations and cuttings in successive layers : allowance should always be made for compression and settlement, particularly in works that are rapidly constructed, by raising the top of the bank above the level at which it will be when the materials of which it is composed have settled together into a solid mass. In forming a bridge or drain, over which an embankment is to be constructed, the masonry should be strong, and the outer surface of the walls and top of the arch covered with concrete to prevent the water from filtering through and destroying the morter. Hydraulic lime should be used in building them. The principal embankments in Eng-land are those in the Fen countries in Cambridgeshire and Lincolnshire, and those constructed to carry parts of many lines of rail, some of which are of great magnitude.

EMBANKMENT, THAMES. (See THAMES EMBANG-MENT.)

dead at home, esteeming it is great comfort to have the bodies of their relatives beside them; and sometimes they were produced at feative entertainments. This was the most expensive mode of embalming, and was adopted only by the wealthiest classes, costing a rate of various kinds. On the breaking out of a war, talent of silver (or about £234). Another and cheaper with may be declared prizes. When it is necessary to conceal any incision, by injecting the viscera with all of cedar, and then steeping the body in natron for

#### Embassy

may be laid upon all vessels, native and foreign, that may be the means of conveying information; and an embargo may also be laid by government upon ships belonging to its subjects in order to employ them in

belonging to its subjects in order to employ them in the service of the country.

EMBASSY, em'-bds-ve (Fr. ambassade), a term applied in general language to a diplomatic mission. In a more restricted sense, however, an embassy is a mission presided over by an ambassador, and is distinguished from an ordinary legation or mission which a intrusted to an envoy or other subordinate authority. The true difference between an ambassador and an envoy is that the former represents the person of an envoy is that the former represents the person of his sovereign, and in that capacity is able to demand a private audience of the monarch to whom he is a private audience of the accredited. An envoy, on the contrary, is obliged to make his proposal to the minister of foreign affairs. Every ambassador is provided with a residence, and cavoys and subordinate ministers receive an allowance There are now five embassies, profor house-rent. perly so called; namely, those at Paris, St. Petersburg, Constantinople, Vienna, and Berlin. (See AMBASSA-

EMPATTLED, em-bül'-tid, in Her., one of the eight crooked or curved lines used, in addition to the straight line, in dividing one part of the field from another, or

line, in dividing one part of the field from another, or for the outline of any principal ordinary. When this outline, or line of division, is in the form of the buttlements of a tower, it is said to be embattled. French heralds use the term crenelle. (See Chenel.)

EMBEDAYS, em'-ber, are certain days of the year set apart by the Church for prayer and fasting, the weeks in which they occur being termed Ember-weeks. The derivation of the term is doubtful. According to some, it is derived from the Greek hemerai, days; according to others, from the Saxon ymbren, a circle or revolution. The Ember-days are the Wednesday, Friday, and Saturday after the first Sunday in Lent, after the feast of Pentecost, after the 14th of Septemafter the feast of Pentecost, after the 14th of September, and after the 13th of December. They were first appointed to be observed by Pope Calixtus in the 3rd century, for imploring the blessing of God on the fruits of the earth, and also for the grace of the Holy Ghost upon the ministers ordained at these times. The Sundays immediately following these seasons are still appointed by the canons of the Church of England for the ordination of priests and deacons.

EMBEZIEMENT, en-lest z-In-most (Nor. embeasiler, to fileh), the fraudulent appropriation by clerks, servants, or others, of money or goods intrusted to their ware, or received by them on account of their employers. This is not an offence at common law, and hence offenders were suffered to escape, until it was made a felony by 39 Geo. III. c. 85. By 7 & 8 Geo. IV This is not an offence at common law, and c. 29, embezzlement is declared to be larceny, and punishable with transportation or imprisonment. By the Criminal Justice Act (14 & 15 Vict. c. 100) it is further made competent to convict for embezzleis further made competent to convict for embezzle-ment persons indicted for larceny, and vice versa. Persons employed in the public service embezzling money or valuable securities are deemed guilty of felony, and liable to penal servitude or imprisonment. For embezzling, stealing, or destroying her majesty's military stores to the value of twenty shillings, the offender is liable to penal servitude or imprisonment; under twenty shillings, to fine corrected punishment or under twenty shillings, to fine, corporal punishment, or imprisonment. By the Fraudulent Trustees Act (20 & 21 Vict. c. 54), provision is made for the punishment of fraudulent misappropriations by bankers, brokers, factors, and other agents, of moneys or property in-trusted to them.

Trusted to thom.

EMBLEM, em-l-lem (Gr. emblema, from en, into, and ballein, to cast), in the primary sense of the word, it means a piece of mosaic, or any work in which bits of one kind of material are inserted or let into another; but, in our acceptation of the term, it is applied to anything which, by association of ideas, appears to be a visible and suitable representation of some abstract quality, or it has a similar meaning to that of the word device. (See Davion.) Thus the lamb is the emblem of meakness, humility, and docility; the lion, of courage and magnanimity; thedog, of fidelity; and the fox, of oraft and cunning. The eagle is the emblem of imperial power, as it is reputed to be the king of birds, and often styled the royal bird. Other things have been

### **Embrecation**

taken as emblems of persons as they are associated with them by historical recollections: thus the gridiron is the emblem of St. Lawrence, as the instrument of his martyrdom; the wheel, that of St. Catherine, for a similar reason. An angel bearing a pen is the emblem of St. Matthew; a lion, that of St. Mark; a bull, of St. Luke; and an eagle, of St. John. Flowers are supposed to be emblematic of various qualities, and are, in consecuence. sometimes used in the East as a means in consequence, sometimes used in the East as a means of communication.

of communication.

EMBOSSING, em-bos'-sing (Fr. embosser, from bosse, a stud), the art of obtaining patterns of any kind, or inscriptions, in relief, on cloth, leather, felt, metal, pasteboard, or paper. It is effected by subjecting the material on which it is desired to raise any pattern to very great pressure, which may be applied vertically by the sharp blow of a die, or by a cylinder. For embossing crests, addresses, &c., on paper and envelopes, a small stamping-machine is used, and the device desired is cut in intaglio on the die. The paper is placed on a piece of soft metal stamped by the die, and therefore having the device in relief, and the impression is obtained by pressing the die forcibly on it by means of a lever. pressing the die forcibly on it by means of a lever. For embossing woollen goods, the cylinders which are used must have the pattern cut on them in intaglio, but for velvets, and embossing paper of any size, the patterns must be in relief. The following is the process adopted when cylinders are used. The engraved cylinders are used. der, or embossing roller, and another of the same diameter, called the bed-roller, are set closely together, and the material is passed between them. The bedroller is made of paper (see CALENDERING), and covered with felt, to prevent it from receiving and retaining any impression from the embossing-roller. The cylinder on which the pattern is cut is made hollow, to receive heated irons, or to be heated by steam. Leather may be embossed by pressure, or by rendering it supple by moisture, and then fashioning it into the desired shape on a mould cut for the purpose. Ornaments for picture-frames and the interior decoratriaments for picture-frames and the interior decora-tion of apartments, which closely resemble carved oak, may be made in this manner. The cloth which is used for binding books is embossed by passing the material between two steel rollers engraved with the required pattern, which are heated by gas jets from pipes pass-ing through the centre of the rollers, which are hollow. When there is any peculiar device on the cover of a book bound in cloth, and there is much gilding about a book bound in cloth, and there is much guding about it, the cloth is first glued to the millboard covers, and subjected to great pressure from the die engraved for the purpose, after it has been laid on an iron piste, which is heated from beneath by gas.

Embrasure, em-brai-zhur (Fr.), in Arch. this term

is applied to the rectangular indentations of a bat-

tlement, or the splayed opening for a door or window.

EMBRASURE, in Mil., the opening made in the parapet of a rampart to allow a cannon to be fired through it. The neck or opening of an embrasure should be as The neck or opening of an embrasure should be as small as possible in front, or at the exterior face of the parapet, to protect the artillerymen who are working the guns from the sharpshooters of the enemy. The breadth of the opening varies from shout 2 feet for 18-pounders to 3 feet 3 inches for 68-pounders and Lancaster guns. That part of the parapet which fills up the embrasure below the opening, and protects the gun-carriage, the muzzle of the gun appearing above it, is called the genouillere. The top of the genouillere forms the sill of the embrasure, and generally slopes forms the sill of the embrasure, and generally slopes forms the sill of the embrasure, and generally slopes outwards. The distance between the sill and the crest of the parapet should be about 4 feet, while the height of the genouillère varies from 2½ feet for guns on solid on travelling standing carriages to 34 feet for guns The cheeks splay outwards from the neck towards the rear or inner face of the parapet, and are inclined to the central line of fire or capital of the embrasure at an angle of eight or ten degrees. In fieldworks, embrasures are revetted with timber and fascines or gabions, and are protected from the flame from the muzzle of the gun by a covering of raw hides. Mantlets or shutters are often used to mask embrasures, and protect the men at the guns from riflemen. They are withdrawn suddenly when the gun is to be discharged, and closed after the fire is given.

Embrocation, embro-kai', shun (Gr. embroche, a moistening), a term originally applied to those exter-

## Embroidery

nal applications used for softening or dissipating nal applications used for softening or dissipating swellings. The word has, however, extended beyond its primary meaning, and is applied to cleaginous and spirituous compounds which incite the surface of the skin to increased action, and produce all the effects of counter irritants, or which, by their influence on the extremities of the nerves, assist in resolving spaem; thus acting as antispaemodics.

EMBROIDERY, em-broid'-er-e (Fr. broderie), a term applied to the art of working ornamental figures upon fabrics of any kind with a needle and thread. The art of embroidery is one of the oldest, and has always been one of the most important domestic occupations among oriental nations. It was practised among the Hebrews during the time of Moses; and the women of Sidon were famous for their embroidery before the siege of Troy. In after-years, the women of Greece were celebrated for their proficiency in the same art; and some of their productions are said to have equalled, if not surpassed, many of the finest naintings then existing. The inhabitants of Peru, paintings then existing. The inhabitants of Peru, when discovered by the Spaniards, were found to have in their possession elaborate embroideries of gold and silver on feathers, which they manufactured with great skill. The ecclesiastical tapestry, curtains, priests vestments, &c., in the middle ages, were all embroidered with the needle; and screens, corridor linings, &c., were the daily handwork of some of the noblest ladies, assisted by their hand-maidens. In the present day, all embroidery may be divided into two classes,— embroidery on stuffs and on muslin. The first class includes all ornamental needle-work upon articles of includes all ornamental needle-work upon articles of furniture, standards, church vestments, &c.; the second is employed usually upon articles of female apparel, such us caps, collars, &c. Stuff embroidery is performed by means of a loom, and is executed with gold, silver, silk, cotton, and woollen threads. Muslin embroidery is generally accomplished by hand, the fabric worked upon being stretched on a frame. This kind of work has been very fashionable of late years; but although at first only looked upon as an elegant accomplishment practised by ladies, it now elegant accomplishment practised by ladies, it now forms an article of considerable traffic, and gives employment to a large number of persons. Berlin-woolwork is a sort of embroidery which has been in vogue
for many years among ladies. The fabric worked upon is generally stretched upon a frame, and the design to be embroidered is drawn upon it, or some other contrivance is employed by the worker. other contrivance is employed by the worker. An engraving, in which lines are drawn corresponding with the threads of the fabric, is generally used. The name is derived from the fact that a printseller named Wittich, in Berlin, up to 1810, sold the best patterns for this kind of work. Machine embroidery has given a great impetus to the art, and about eight years ago a machine was invented by M. Heilmann, of Mulhausen, by which one person could guide 80 to 140 needles, all working at the same time. This machine was exhibited in the French Industrial Exhibition of 1854, and was afterwards natested in England. All 1854, and was afterwards patented in England. All the English rights were afterwards purchased by Mr. H. Houldsworth, the eminent silk manufacturer of Manchester, who greatly improved the machine.

Emberge, em'-bre-o (Gr. embruon, from embruo, I bud forth), is the rudimentary state of any organized body. In Physiol. it is applied to the foctus in utero before the fifth month of pregnancy, from its growth resembling the budding of a plant. Hence we have embryology, a description of the embryo; embryotomy, or the extraction of the embryo piecemeal in delivery.

EMBEYO, in Bot., the rudimentary plant existing in EMBEYO, in Bot., the rudimentary plant existing in the seed. The presence of a true embryo is the essential characteristic of the seed of flowering plants; for a spore, as the reproductive body of a flowerious plant is called, has no true embryo, the rudimentary plant being only developed from it after its separation from the parent. Three parts, corresponding to the root, stem, and leaves of the perfect plant, are distinguished in the embryo, and are termed, respectively, the rudicle, the planuale, and the cotyledons. These parts may be readily recognized in many seeds, especially when the process of germination is a little advanced. Plants which have seeds with two cotyledons are said to be which have seeds with two cotyledons are said to be dicotyledonous, and those which have seeds that commonly possess but one cotyledon are said to be mone-

cotyledonous. The spores of flowerless plants having no true embryos, can have no cotyledons; hence such plants are said to be acotyledonous. When albumen is present in a seed, the size of the embryo is in inverse proportion to it: thus in grasses there is a large deposit of albumen, but a very small embryo; while in the nettle the embryo is large and the albumen small. When the embryo is external to the albumen and in contact with the integuments, as in grasses, it is described as external; when it is surrounded by the albumen on all sides, except at its radicular extremity, as in the paney, it is said to be internal.

EMBRALD, em-er-dld (Fr. émerande), in Min., one of the precious stones, of a rich deep green colour, occurring in hexagonal prisms in granite, gueiss, and mica rocks. The finest emeralds, however are found in dolomite in Granada. The duke proportion to it: thus in grasses there is a large de-

ever, are found in dolomite in Granada. The duke of Devonshire possesses an emerald from this lo-cality measuring two inches in length by one in diameter. Fine specimens also occur in Peru, and inferior ones in Bavaria, India, and Siberia. Some specimens from the latter country measure 4; inches in breadth and 12 in length; but they are worthless as gems, being full of strice, and not transparent. Chemically, the emerald consists of 65 silica, 14 alumina, 13 glucius, 2.56 lime, and 3.50 oxide of chromium. distinguished from beryl by its more brilliant colour, being coloured with oxide of iron instead of oxide of chromium.

EMERALD, ORIENTAL, in Min., a green variety of

sapphire. (See SAPPHIRE)

EMBERSION, e-mer'-shuu (Lat. e, from, and mergere, to plunge), in Astron., the term applied to the reappearance of a heavenly body from behind another, after the former has been hidden from view by the passage of the latter across its disc, as in an eclipse.

EMERY, em'-e-re (from Cape Emeri, in the island of EMERY, em: e-re (from Cape Ellier), in the island of Naxos), in Min., b variety of corundum, consisting mainly of alumins, combined with a small quantity of silica, peroxide of iron, and a little water. Dr. Lawrence Smith states that those varieties containing rence Smith states that those varieties containing least water are, exterie paribus, the hardest. Emery occurs in Spain, Asia Minor, in the Greek islands, and in the island whence it takes its name. Ground to powder of different degrees of fluences, it is much used in the arts as a polishing powder. It is mostly employed attached to choth or paper. Emptres, e-met-like (Gr. emetike), a term applied to those medicines which influence the stomach in a permitir renewal and of the production and produce.

culiar manner, so as to invert its action and produce vomiting. This effect is caused not by the quantity of the matter introduced, but by the nature of the emeticitself. Emetics are administered in many cases of illness. They are useful when it is found necessary to relieve the stomach of some hurtful or indigestible substance. Lives that have been endangered either substance. Invest that have been endaughered either by poisons or excess of food have frequently been saved by means of emetics. In cases of fever, emetics are used: it is supposed that the copious secretion which they produce from the glands of the stomach and intestines has a direct curative action. In all cases of fever, emetics should be administered at as early a stage of the disease as possible. They invariably render the disease milder, and may be advantageously repeated even at a more advanced stage, as tageously repeated even at a more advanced stage, see they induce sleep and a moist state of the skin. They are specially efficacious in epidemic, typhus, common fever, and enanthematous fevers, especially measles, scarlet fever, and small-pox. According to the opinion of Dr. James Clark and Dr. Carswell, emetics are able in the stage of the property of the control of the contro to dislodge tubercular matter from the lungs in the to dislodge tubercular matter from the lungs in the earlier stages of consumption. Emetics, however, should always be given with great caution, since, in cases of depression of the system, their action is to produce nausea, by which the vital power is always diminished. The emetics generally used consist of preparations of antimony, zinc, and copper. Squills, lobelis, ipecacuanha, and other substances, are also employed. Mustard and water diluted is one of the mildest and most generally used emetics. Emetics should never be administered to a patient who is disposed to apoplexy, or a tendency of blood to the head, or where the patient is liable to hemorrhage from any organ, or is subject to hernia. During pregnancy, also, emetics must be avoided.

Entigration, eme-grai-shun (Lat. e, and migrare, to remove to another place to dwell in), is the movement of one or a number of persons out of one place or country with a view to their settling in another, into which they are said to immigrate (Lat. in, and migrare). As commonly used in the present day, however, the term has a more limited sense, being applied to the leaving of an old and thickly-peopled country to settle in one but sparsely inhabited. The great emigration fields at present are the British pos-sessions and the United States of North America, Australia, New Zealand, and South Africa. In 1860 the total number of emigrants from this country was 127,069; of whom 103,001 were from England, 3,872 from Scotland, and 21,596 from Ireland; 9,786 were from Scotland, and 21,506 from Ireland; 9,788 were for the North American colonies, 87,000 for the United States, 24,302 for Australia and New Zealand, and 6,881 for other places. The total number of emi-grants from the United Kingdom, from 1815 to 1860 inclusive, was 5,046,067. The subject of emigration has given rise to various important questions among political economists. It was long a prevalent notion that emigration, as tending to weaken a nation, ought to be discouraged; but sounder views on this subject now prevail, and the government has adopted various measures for the encouraging of this movement. In 1831 a government commission on emigration was formed, by which officers were appointed both at home and in the North-American colomes to watch over the interests of emigrants, and to furnish them with necessary information. In 1840 commissioners were appointed under the royal sign-manual to act as a land and emigration board. This board forms a subordinate department of the Colonial office. It regulates the sale of the waste lands of the crown throughout the colonies, and applies the proceeds of such sales towards the removal thither of emigrants from this country. It is the duty of the commissioners to see that the provisions of the Passengers Acts (15 & 16 Vict. c. 44, and 18 & 19 Vict. c. 119) are observed, which they do by means of agents, established at the several outports, who examine into the seaworthiness and fitment of emigrant vessels, the amount of provisions and water on board, the number of passengers, their healthy condition, and the various other matters required by the act. These agents further procure and give gratuitously information as to the sailing of ships and the means of accommodation for emigrants, and whenever applied to for that purpose they see that all agreements between shipowners, agents, or that all agreements between shipowners, agents, or masters, and intending enigrants, are duly performed. Emigration is one of the modes of relief provided by the Poor Law Amendment Act, 4 & 5 Will, IV, 2, 76, which empowers owners and ratepayers to raise money on accurity of the rates for the purposes of emigration. Free emigration can 'rarely or never be detrimental to a country, and there are many cases in which it is highly expedient to aid and encourage it. 'The late extraordinary emigration from Ireland (1846-54)," says McCalloch, "has done more perhaps to improve its condition than anything else that could have happened. In consequence of the diminution have happened. In consequence of the diminution that has been effected in the population, employment is more easily obtained, and the rate of wages has increased; a considerable progress has been made in many parts of the country in the consolidation of small patches of land into something like farms of a reasonable size and susceptible of a better system of cultivation; the towns and workhouses have been in part, at least, relieved of their pauper population; and agitation, crime, and outrage are less prevalent. Nor agitation, crime, and outrage are less prevalent. Nor is there any reason to fear that either in Ireland or anywhere clse emigration will be, or indeed can be, carried to excess.

carried to excess."

EMEGRES, em'-e-graiz (Fr.), a term applied to those individuals who left France during the revolution. After the taking of the Bastille, the princes of the royal family, Monsieur (Louis XVIII.), the count d'Artois (Charles X.), and the prince de Coudé, departed from France. They were speedily followed, in 1791, by all those who considered that their rights, we will again and property hash been interfered with im-1791, by all those who considered that their rights, privileges, and property had been interfered with improperly. Noblemen left their estates and domains, officers, with large numbers of private soldiers, priests, monks, and private individuals, passed over into Ger-

many, Belgium, Holland, Switzerland, and Piedmont. Very few of the émigrés had been able to save any property, and the greater proportion were consequently soon in a dreadful state of destitution. The princes themselves formed a court at Coblenz, with a government, ministers, and a court of justice. Com-munications were kept up with the foreign courts, and thus the feelings of the revolutionary party in France were more and more embittered against them. At last a body of émigrés, under the command of the prince de Condé, followed the Prussian army into Champagne. The republican government immediately put the strongest laws in force against the *émigrés*. Any person found assisting or favouring them in any way was condemned to death, and the lands of all *émigrés* were confiscated. Although many of them had refused to fight confiscated, Although many of them had refused to fight against their country, 30,000 persons were put upon the list, and condemned to perpetual exile from the soil of France. The last attempt made by the émigrés to penetrate into France by force of arms was in 1795, at Quiberon. The attempt was a failure, and the force belonging to the prince de Condé was broken up after the peace of Luneville, and sought a refuge in Russis. Under the Directory, many of the émigrés tried to return to France, and in 1801 Napoleon I. granted them a general amnesty. By the largest proportion this was bailed with delight, and they returned to their native land. Many, however, did not return until after the restoration of Louis XVIII. Those until after the restoration of Louis XVIII. Those who had remained loyal received many honours from the king, but were unable to regain their estates or their privileges, on account of the charter of 1814. In 1825, those *émigrés* who had lost their landed estates received a compensation of 30,000,000 francs yearly, on the capital of 1,000,000,000 francs. This great was, however, repealed during the July revolution.—Ref. Histoire des Emigrés Français, by Antoine de Saint Gervais Gervais.

EMIR, em'-cer (Arab.), a title bestowed in the East upon all the real or supposed descendants of Mahomet, and his daughter Fatima. The term is also applied to all independent chieftains, not only in the East, but in the north of Africa. In Turkey, the prerogatives of the north of Airca. In Turkey, the prerogatives of the emirs are unimportant, the principal being their exclusive right to wear turbans of a green colour, which was a favourite of the Prophet. Those who are emirs from the mother's side are held in higher estimation than those from the father's. All the Turkish emirs are placed under the superintendence of the Emir Parki The Ladder in case of wear of the Emir-Beshir. The leaders, in case of war, during early Mahommedan history, were called emirs, and the word has been used in connection with several es. The califs style themselves "Emir-al-Mume-prince of the Faithful; at the present time, in offices. Turkey, the title is applied to the rulers of provinces. The master of the horse to the sultan is called Emir-Achor; the standard-bearer, Emir-Alem; and the sur-

veror of markets, Emir Bazaar.

EMOLLIENTS, e-mol'-yents (Lat. mollis, soft), a term employed to denote those substances which are used externally, in medicine, for the purpose of softening the part of the body to which they are applied. They are mostly used in the form of poultices, fomentstions, &c.

EMOTION, e-mo'-shun (Lat. e, and moreo, I move), in Mental Phil., is a term frequently used as synony-mous with feeling, but which is strictly a sixte of feeling awakened through the medium of the intellect, and manifesting its existence and character by some and mannesting its existence and character by some sonsible effect upon the body. An emotion differs from a sensation in not springing directly from an affection of the body, and from a cognition, by its being pleasurable or painful. According to Lord Kames, an emotion differs from a passion in this, that it masses away without spring any desire, whereas it passes away without exciting any desire, whereas a passion is accompanied by desire. Emotions, regarded in themselves, can scarcely be called springs of action. They tend rather to quiescence and contemaction. They tend rather to quiescence and contemplation, fixing the attention on the objects or occurrences which have excited them. But they combine with springs of action, and give them a character and a colouring. The physical changes that uniformly accompany the mental passions and emotions show clearly the intimate connection that exists between the inward states of consciousness and the physica er

#### Emperor

corporeal organism. This is in some measure ac-counted for from the natural tendency of pleasure to cause an increased flow of the blood and vital energies This is in some measure accause an increased flow of the blood and vital energies to particular parts, and of pain to cause a depression or weakening of the vital functions. Why some special muscles should be affected differently from others,—why, for instance, anger should draw down the eyebrows and compress the lips, is a question that has not yet been satisfactorily solved.

has not yet been satisfactorily solved.

EMPEROR, em'-pe-ror (Lat. imperator), the supreme monarch of a nation; a title, the dignity of which is considered to be superior to that of a king. Originating with the Romans, and signifying merely the individual who had the imperium or ruling power, it gradually began to mean the possessor of the sovereignty of the Roman world. From the Romans, the title passed to Charlemagne, and when the Carlovingian family died out in the German brauch, the title became elective. elective. At present, there are three emperors in Europe,—the emperor of the French, an elected monarch; the emperor of Russia; and the emperor of Austria.

EMPEROR MOTH (Saturnia Pavonia minor), one of the most beautiful of the British species of moths. The expanse of its wings is about three inches. The colour is a greyish brown, tinged with purple; the back part of the wings has a band of pale brown and purple, the last band being much waved. In the centre of each wing is a large spot consisting of a black pupil with a yellow or grey iris, partly surrounded by a light blue crescent. The larva is of a green colour, pupil with a yellow or grey life, party surrounce of a light blue crescent. The larva is of a green colour, with a black band on each segment, ornamented with pink tubercles, bearing a whort of six hairs, diverging like a star. The cocoon of the emperor moth is very curiously constructed, the extremity not being closed, euriously constructed, the extremity not occupant but terminated by a converging circle of stiff hairs, which enables the insect to make its escape, but which enables the insect to make its escape, but entirely prevents the entrance of all intruders. This moth is of the same family as the silkworm moth (Bombycide), and the largest European species is the peacock moth (Saturnia pavonia major), which attains a width of five inches between the wings.

EMPETRACE, empe-trai-se-e (Gr. en, upon; petros, a rock), in Bot., the Crowberry fam., a small nat. ord, dicotyledonous plants in the sub-class Monochlamydes. They are small heath-like evergreen shrubs, mostly natives of northern Europe and North America. Their leaves and fruit are generally elightly acid. The berries of Empetrum nigrum, the crowberry, are eaten in the very cold parts of Europe, and are also employed in Greenland to prepare a fermented liquor. In Portugal the berries of Corema are also used in the preparation of a beverage which is said to have a medicinal value in febrile complaints.

EMPHASIS, em'fä-sis (Gr. en, and phemi, I speak), in pronunciation, is a mode of denoting one or more words in a sentence by a stronger and fuller sound of voice, in order to draw attention to them, or to show how they affect the rest of the sentence. Sometimes the emphatic words must be distinguished by a particular tone of voice, as well as by a stronger accent, On the right management of emphasis depends the Bre of pronunciation. With no emphasis, speech will be heavy and lifeless, and the meaning often ambiguous; and if the emphasis be misplaced, the meaning may be entirely perverted. There are two kinds of emphasis,—the simple and the complex; the friends of emphasis,—the simple and the complex; the former serving merely to point out the plain meaning of a sentence, the latter to mark some affection or emotion of the mind, or to give a meaning to words which ther do not usually bear. In writing, an emphatic word is commonly underlined, and in print it is usual to put it in italics.

EMPIRE, em'-pive (Lat. imperium), a term originally applied to that territory or extent of land governed by an emperor. The first empire was that of the ancient Romans, and it was divided into two great portions,—the empire of the East, or the Lower Empire, and the empire of the West. The empire of the East was greatly subdivided, according to the reigning dynasty. The empire of the West became the German, or Holy Roman empire, in the ninth century. At the pre-sent time the word empire is used to express any large extent of dominion. Thus, in erdinary language, the is customary to speak of the empire of Hindos-760

tan and the empire of Persia. The dominions of the queen of England are universally called the British

empire. Those countries in Europe which are empires empire. Those countries in Europe which are empires governed by emperors are France, Austria, and Eussia. Emprise, empiritos, from empeirio, experience), is properly one whose knowledge is founded on experience or observation. A certain sect founded on experience or observation. of Greek physicians took this name to denote their mode of treatment, as distinguished from that of the Methodists and Dogmatists. They died out, and are preserved only in the works of their adversaries; and preserved only in the works of their adversaries; and hence the term has long been synonymous with a charlatan or quack doctor, or more generally an ignorant pretender in science. In philosophical language, the term empirical means simply which belongs to, or is the product of, experience or observation, as distinguished from what is the result of reasoning or inference.

EMPORIUM, em-por'-e-um (Gr. emporion, tradiug-place), the term applied to receptacles in which wholeplaces), the term applied to receptacles in which wholesale merchants stow their goods in seaport and other towns. The word is originally derived from the Greek word smpores, which signified in the time of Homer one who sailed in a ship belonging to another. It afterwards was applied to a wholesale merchant, and in later years gained its present signification.

EMPYHRAM, cm-pi-re'-in (Gr. empuros, from sn, and sure first) a term mobiled by noute and others to the

pur, fire), a term applied by poets and others to the highest heaven, where the pure element of fire is supposed to exist. Milton frequently makes use of the word in "Paradise Lost;" as in the following lines:—

"Almighty Father from above,

From the pure empyrean, where he sits, High throued, above all height, bent down his eye."

EMU, e'-mu (Dromains Novo Holliandia, or Dromains ater).—This bird is widely diffused over the southern part of Australia, and is closely allied to the cassowary. When fully grown, it measures seven feet in length. The plumage is, for the most part, a mixture of grey and brown, paler below than above; head cowith feathers, which, together with those about the neck, are of a hairy texture. The long feathers observable in the wings of the cassowary are wanting in the enu; but instead of them it has real wings, though of so small a size as to be useless for flight. The legs are short and stout; there are three toes to each foot, and these are furnished with nearly equal claws. It is very swift, and when attacked kicks, does the ostrich, but not forwards, as does the latter bird, but more as a cow kicks, sideways or backwards. The nest of the emu is made by scooping a shallow hole in the ground in some scrubby spot; concerning hole in the ground in some scrubby spot; concerning the formatice of the nest, however, there are various opinions. Its eggs are dark green, and the number laid varies from seven to thirteen. Dr. Bennett remarks there is always an odd number, some nests having been discovered with nine, others with eleven, with thirteen. In sixt the arms, and others, again, with thirteen. In size the emu's eggs nearly equal those of the ostrich. They are eggs nearly equal those of the ostrich. They are monogamous, and the males, as in the case of the she's, perform the duties of incubation. The eggs are sales, person the dudes to include the reggs are eagerly sought after by the natives as an article of food, as is also the bird itself for the sake of its flesh, which, particularly that about the hind quarters, is said to be of good flavour. The emu would seem to have been unknown in Europe until the 16th century, when the Dutch, on their return from one of their earliest voyages to India, brought one from the island of Tara, For a considerable time this bird was exhibited for money at Amsterdam, and finally it came into the hunds of the emperor of Germany. In the year 1871 an emu was sent by the governor of Madagascar to the king of France, which was kept slive for four years in a menagerie at Versailles. A peculiarity in the anatomy of the emu should be noticed. "It is the largest bird after the estrich, from which it differs sufficiently in its anatomy, for it has short intestines and small coces, wants the intermediate stomach between the crop and the gizzard, and its cloaca does not in proportion exceed that of other birds."—Chuier. the Dutch, on their return from one of their earliest Cuvier.

ENAMEL, ENAMEL-WOEK, e-ndm'-el (Fr. émail).— The art of applying a coating of vitreous substances called enamels to a surface of glass or metal, and

Enamel

baking this in by a fusing heat, is termed enamelling. in the ordinary processes of the art the substances used to form the ground of the enamel are opaque, and must bear a higher degree of heat without fusing than the coloured enamels which are afterwards melted into them. They are made after a great variety of receipts, according to the uses to which they are to be applied. All those designed for metallic surfaces have a transparent base, which is rendered opaque by the substitution of combined oxide of lead and oxide of tin, instead of the oxide of lead used as one of its ingredients. Five different mixtures of the two oxides are in use, the proportions varying from 3½ parts of lead and 1 of tin to 7 parts of lead and 1 of tin the desired proportion are melted. The two metals in the dealers proposed as a state together, and the combined oxide is removed as fast as it appears upon the surface. When the oxidation is as thoroughly effected as is practicable, the product is well washed to remove any particles of metal that may have escaped oxidation, as these would greatly impair the quality of the enamel; for the same reason, it is essential that the metals themselves should be absolutely pure and free from the usual alloys found with them. One or other of the mixtures of oxides obtained by the method described is next melted with proper quantities of silica (pounded quartz), saltpetre, and a little borax: the last gives greater fusibility as its proportion is increased, and no more is used when enamel is to be applied upon copper or silver than upon gold. The plates are sometimes chemically acted upon by the enamel, and if the gold of the gold plates is alloyed with too much copper, the effect of this is perceived in injuring the appearance of the enamel. For making coloured enamels, either the opaque or transparent enamel serves us a base, and with it is melted a suitable proportion of some metallic oxide metted a suitable proportion of some metalic oxide as a colouring matter; for a blue enamel, the opaque is used with oxide of cobalt; for a green, oxide of chromium or binoxide of copper; for a violet, per-oxide of manganese; for a yellow, obloride of silver; for a purple, purple of Cassius; and for a black, the for a purple purple of Cassius; and for a black, the transparent ensmel is used with mixed oxides of copper, cobalt, and manganese. The different enamels, being prepared beforehand, are, when required for use, crushed to powder and then kept at hand under water, in vessels well covered, to protect them from all impurities. The metallic surfaces to be coated are cleaned by boiling in an alkaline solution, and are then washed with pure water. The copper alloy in gold may be dissolved from the surface by boiling in a strong solution of 40 parts of saltpetre, 25 of alum, and 35 of common salt. The enamel for watchfaces is made from arsenic instead of tin. Enamelalum, and 35 of common sait. The enamet for watch-faces is mude from arsenic instead of tin. Enamel-ling is an art of great antiquity. The ancient Persians and Arabians appear to have practised it upon earthenware and porcelain. The Egyptians also practised the art, and from them it is supposed to have passed to the Greeks, and thence to the Roman. That the Saxons were adepts in the art is proved by an enamelled jewel preserved at Oxford, bearing an inscription stating that it was made by order of the great Alfred. With regard to the different and delicate process of painting on enamel, Mr. Digby Wystt, in a paper read by him before the Society of Arts, describes the art as having passed through six stages from the time of its origin as a species of mosaic-work. The Byzantine Style was the earliest, and was in use The Byzantine Style was the earliest, and was in use in the Byzantine empire from the reign of Justinian down to the year 1300. Its most celebrated exponent was the artist-monk Theophilus. The process was chiefly characterized by the formation of cells, or compartments of gold fligree, in which the enamel was lodged. The Early Limages Style came next, taking its title from the city in which it was much practiced between the alevanth and fourteanth compractised between the eleventh and fourteenth cenprecision between the derivative and indirection centuries. In this method the cavities for the reception of the enamel were incised by a graver in a thick plate of copper. The third, or Early Italian Style, was practised between the thirteenth and sixteenth pusse of copper. Incoming, or nearly trauser style, was practised between the thirteenth and sixteenth centuries. The best-known exponent of this method was Ugolino Veri, who in 1338 made the shrine of Orvieto Cathedral. This swie seems to have taken a position midway between the old incised enamel and observated enamels which at a mback-man position. the painted enamels which, at a subsequent period, came in vogue. "It consisted," says the English

Cyclopedia, "in engraving on silver after the manner of medallic relief, and then floating it over with variously-coloured transparent pastes." The first to describe the process which has obtained the name of the Jewellers' Style was the celebrated Italian artist the Jewellers' Style was the celebrated Italian artist Benvenuto Cellini. In this process small objects of gold or silver, in the round or in high relief, were covered with a glass-powder paste, which was held in its position until vitrifaction was completed. The Late Limoges was the fifth style, and in this process the Late Limoges was the fifth style, and in this process the paintings were laid on in transparent colours upon an opaque paste. The chief characteristics of the sixth, or Miniature Style, were the introduction of a number of intervaluation of a greater number of firings, and a greater graduation of tints. This process, which is almost identical with that practised at the present day, may be regarded as that description of enamelting which most fully comes within the definition of fine-art work. Thus far we have treated the subject of enamel-work by describing its character and of application, also as a branch of the fine arts; but we have yet to consider enamelled ware as a manufactured product. About the commencement of the present century, Dr. Samuel Saudy Hickling obtained a patent for a process of enamelling cast-iron and other hollow were for saucepans, &c. His specification other hollow ware for saucepans, &c. His specification described the coating of iron vessels, &c., by fusion with a vitrifiable mixture composed of six parts of calcined flints, two parts of composition, or Courish stone, nine parts of litharge, six parts of borax, one part of argillaceous earth, one part of nitre, six parts of calx of tin, and one of purified potash. Or eight parts of calcined flints, eight of red lead, six of borax, six of calx of tin, and one of nitre. Or twelve parts of potars compatition eight of horax taus of parts of potter's composition, eight of borax, ten of white lead, two of nitre, one of white marble calcined, one of argillaceous earth, two of purified potash, and five of calx of tin. Or, lastly, four parts of calcined fint, one of potter's composition, two of with a contract of the calcined fint of home one of white marble calcined. of calcined flint, one of potter's composition, two of nitre, eight of borax, one of white marble calcined, half a part of argillaceous earth, and two of calx of tin. Whichever of these compounds be taken, it must be finely powdered, mixed, and fused. The vitreous mass is to be ground when cold, sifted, and levigated with water. It is then made into pap with water or gum-water. This pap is smeared or brushed over the interior of the vessel, dried, and fused with a broper heat in a muffle. Calcined bones are also suggested as an ingredient of a flux. The fusibility of the vitreous compounds will ware according to the heat gested as an ingredient of a flux. The fusibility of the vitreous compounds will vary seconding to the heat to be applied to the vessel, by using various proportions of the silicious and fluxing materials. Colours may be given, or gilding. In the year 1839 Messrs. Clarke secured by patent the use of the following composition and method:—100 lb. of calcined ground district the falls of the following composition and method:—100 lb. of calcined ground Clarke secured by patent the use of the following composition and method:—100 lb. of calcined ground flints, and 50 lb. of borax calcined and finely ground, to be mixed, fused, and gradually cooled. Of this 40 lb. are mixed with 5 lb. of potter's clay, and ground in water to a pasty mass. The vessel, after being thoroughly cleansed, is lined with a coating of this about \$\frac{1}{2}\$ of an inch thick, and left for it to harden in a warm room. A second coating is added, prepared from 125 lb. of white glass without lead, 25 lb. of borax, 20 lb. of soda in crystals, which have been pulverized and fused tegether, ground, cooled in water, and dried. To 45 lb. of this compound 1 lb. of soda is added, apon which the whole is mixed in hot water, dried, and pounded. Of this a portion is sifted over the other coating whilst still moist, and dried in a stove at a temperature of bolling water. The vessel is then heated in a stove or muffle till the glaze fuses. It is taken out, more glaze powder in subjected to heat. By this and other processes enamelled culinary and other utensils have now become chasp, and been caused to enter into common use. enamelled culinary and other utensils have now become cheap, and been caused to enter into common use. At the present time, among other processes, we find iron plates covered with coloured enamel, so as to imitate marble. Examelling of alates to imitate marble was introduced by Mr. G. E. Magnus at the Great Exhibition of 1861, for which a prize medal was awarded the inventor. The slates are first of all sawed, and planed to a uniform thickness, after which they are rubbeg amoch with polishing-stones. The ground-colour adapted to the marble to be imitated in

# Encampment

first laid on, and afterwards the variegated colours. The slate is then placed in an oven heated to 200°, and The slate is then piaced in an oven neared to zuv, and allowed to remain one night. In the morning, after cooling, a coat of varnish is applied, and the slab is once more placed in the oven, where it remains till the next day. Other heatings and varnishings succeed, once more placed in the oven, where it remains till the next day. Other heatings and varnishings succeed, till finally the process is completed by the polishing of the slab with pumice and rotten-stone.—Ref. Notice des Emuse exposés dans les Galeries du Louvre, by Count de Labords; Ure's Dict. of Arts, Manufactures, and Mines, 6th edition.

to in or into, and kaio I burn), a method of painting that was practised to a great extent among the ancients, from the time of Alexander the Great until the 7th or 5th century, from which time the art

the ancients, from the time of Alexander the Great until the 7th or 8th century, from which time the art gradually declined until the 1th century, when it seems to have been abandoned, and a practical knowledge of effecting it entirely lost. According to the historian Pliny, there were three methods of performing the process; the first and second seem, however, to be almost, if not entirely, identical; the first height the method of producing large pictures, and the ever, to be almost, if not entirely, identical; the first being the method of producing large pictures, and the second, of producing designs in miniature. In the first kind, the colour that was intended for the ground of the picture, after having been mixed with wax as a vehicle, was smeared over the surface of the wall or panel on which the painting was to be made, and carefully flattened. The design, whether it was a figure or an arabesque border or scroll-work, was traced on this ground with a sharp-pointed instrument, and the ground carefully removed, leaving the figure in a sort of shallow intaglio. The wall beneath was allowed sort of shallow intagito. The wan beneath was showed to show through, or the hollow was filled with wax colouring matter of another tint; after which the whole was blended together with a hot iron, a process which removed all traces of the junction of the different colours, and imparted a brilliant gloss to the tints that were used. The second method, in which the work was executed on ivory, must have been similarly done, and the wax colour which had been spread over the ivory removed by the graving-tool, to allow the surface of the ivory to furnish the design, or the design was out out on the ivory in intaglio, and the hollows thus obtained were filled with coloured wax. In the third had been spread over the colours ware loid on with a breach kind, in which the colours were laid on with a brush the colouring matter was mixed with wax dissolved in turpentine or some essential oil. The colours were laid on in a liquid state, and from the use of the brush an effect of light and shadow was obtained which it was impossible to produce in the other methods above was impossible to produce in the other methods showed described. When the picture was completed, the tints were blended together with a heated iron as before. About 1750, the lost art was recovered, and the practice of it revived, by M. Bachelier and Count Caylus in France. Both produced pictures in this style, and an account of the method need was published. It was warmly taken up throughout the south of Europe for some years, when it again fell into disuse. It was revived again at Munich in the reign of King Louis of Bavaria, and the interiors of many apartments in his palace, and various public buildings erected under his auspices, were executed in it. Since this under his auspices, were executed in it. Since this time, many fine works in this brilliant style of painting fave been produced; but it is far better suited for decorative work than for portraits, figures, or land-scapes.—Ref. Eastlak's Materials for a History of Painting in Oil; Montabert's Traité Complet de la Peisture, vol. viii.

ENGAUSTIC TILES, small earthenware tiles used for paving the passages in the nave and aisles of churches, and also the chancel. They are also used for paving entrance-halls and the vestibules of houses. They eare for the most part in two colours, red and vellow

are for the most part in two colours, red and yellow

are for the most part in two colours, red and yellow being most commonly used, and they are so called because they have a light arabesque pattern figured on them on a dark ground, or vice vered, in imitation of the early encaustic painting of the ancients. Excente, on(0)-sayn(q)t' (Fr.), in Mil., the name given to the inner and continuous line of defence works round any place; thus the line of bastions and intervening curtains inclosing the polygonal space which forms the interior of any citadel is termed the enceints. enceinte.

# Encyclopædia

ENCEPHALARYOS, en-sef-di-as-tos (Gr. enkephalos, that which is in the head; artos, bread), in Bot., a gen. of the nat. ord. Cycadaces, composed of elegant palm-like trees and shrubs, mostly natives of South Africa and Australia. From the stems of various species a kind of sago, called Caffre bread, is obtained.

ENCHANTMENT (Sea March 1988)

ENCHANTMENT. (See MAGIC.)
ENCHÉ'S COMET, eng'-kes, a comet of periodic recurespecially directed when it was discovered by M. Pons at especially directed when it was discovered by M. Pons at especially directed when it was discovered by M. Pons at elements to those of comets which had been observed in 1786, 1795, and 1805, led M. Enclet to calculate its in 1785, 1785, and 1895, led M. Engle to calculate its orbit, and he found the period of its revolution at that time to be just about 1,211 days. The comet reappeared in 1822, and on comparing its elements, and the time of revolution, with those of the comets of the years above monitioned, it was found that they were only successive apparitions of the same comet, and only successive apparitions of the same comet, and that it regularly appeared at its perihalion at intervals of rather more than 1,211 days. It was also found that its period of revolution was gradually growing shorter, at the rate of nearly three hours per revolution, which caused M. Encké to imagine that it was occasioned by some very slight resisting medium spreading throughout the whole of our solar system. It was named after M. Encké, instead of M. Pons, its discoverer in 1818, on account of the success of the former in determining its orbit and period of revolution, and predicting its reappearance in 1925, which happened at the time he had named for it.

mappened at the time he had named for it. ENCORE, on(g)-kore' (Fr.), literally, 'again,' 'once more,' an expression commonly used in places of public amusement by the audiences to express their wish for a repetition of a particular part of the per-

formance; as a song, &c.

ENCRINITE, en'-krin-ite (Gr. en, and krinon, a lily), in Geol., any fossil crinoid, or lily-like cchinoderm. (See CRINOIDEA and ECHINODERMATA.) The encrinites, which form a most important class of fossils, are characterized by their long many-jointed stalks, sur-mounted by flower-shaped bodies, which were furnished with numerous finger-like rays, capable of closing and expanding. Their internal calcarcous skeletons in expanding. Their internal calcareous sketetons in scattered joints and fragments are so abundant in scattered joints and fragments are so administ in some carboniferous limestones as to compose the greater portion of the mass; hence the term encrinal or encrinital limestone. The minuter joints of the flagers and rays are usually termed entrocki, or wheelstones, and the limestones in which they abound, entrockal limestone. The stalk of the encrinite was perforated by a canal, which kept the whole in vital sections and the excepted is only the reconsequently. perforated by a canal, which kept the wholen what action, and the separated joints have consequently some resemblance to beads,—a resemblance which has obtained for them the common names of "St. Cuthert's beads," "wheel-stones," and "pulley-stones. It is usual to apply the term Energiates to the general bearing accorded and amouth stans, though having now having rounded and smooth stems; those having pentagonal and ornamented atoms being termed Pentacrinites; those having pear-shaped receptacles, Apiocrinites; and those with receptacles forming more or less perfect cups, Cyathocrinites. Geologically, the encrinites range from the Silurian up to the present epoch. nites range from the Silurian up to the present epoch. They occur most abundantly in palsezoric and mesozoic strata, rarely in cainozoic, and are now only represented by the comatula or feather-star, and the all but extinct pentacrinus of the West Indies. Like the corals, their function seems to have been, to a great extent, the secretion of lime from the ocean,-whole

extent, the secretion of lime from the ocean,—whole strata of limestone, silurian and carboniferous, being almost entirely made up of their remains.

ERCYCLOPEDIA, or CYCLOPEDIA, en-si-klo-pe'-de-ā (Gr. paideia en kuklo, instruction in a circle), is properly a work professing to give instruction in the whole circle of human knowledge. The two terms are used synonymously; but the former is regarded as the more correct, as denoting "in a circle;" whereas the latter may mean, "of a circle." The use of the word, however, in its present signification, is entirely modern. With the ancients, encyclopædia was applied to the whole circle of learning, a knowledge of which was necessary to constitute a liberal ledge of which was necessary to constitute a liberal education. It comprised grammar, music, geometry, astronomy, and gymnastics. Various works of the ancients attempted to embrace the entire circle of

knowledge; but they exhibit no plan, and are only confused accumulations of the then known arts and sciences. It does not, lowever, appear that the anoisnts ever applied the term encyclopedia to any work of that kind. So far as is known, the name appears to have been first used in this sense by Alforabius, a learned Arab who flourished in the 10th century, and whose work, remarkable for its learning and completeness, is preserved in MS. in the library of the Escurial at Madrid. The indefatigable Dominican Vincent of Beauvais, who flourished about the of the Escurial at Magrid. The interniguous Dominican Vincent of Beauvais, who flourished about the middle of the 13th century, gathered together with wonderful diligence the whole knowledge of his time in three works: "Speculum Historiale," "Speculum Naturale," and "Speculum Doctricale," to which was soon afterwards added, by an unknown hand, "Speculum Morale." But these, and similar subsequent works of the middle-age period, which appeared under the title of "Summa," or "Speculum," manifest throughout a total want of a philosophic spirit. Several works bearing the name of Cyclopadia, or Encyclopadia, appeared in the 16th century; as Ringelberg's "Cyclopadia." (Basel, 1541), and Paul Scalich's "Encyclopadia, see Orbis Disciplinarum tum Sacrarum tum Profanarum" (Basel, 1559). In the beginning of the 17th century, appeared a work of no small merit,—Matthew Martin's "Idea methodicae et brevis Encyclopadiae, sive Adumbratio Universitatis" (Herborn, 1606); but the most noted and valuable of the early encyclopadias was that of John Henry Martin's and the statement of the carty encyclopadias was that of John Henry the early encyclopedias was that of John Henry Alstedius, a professor at Weissembourg, in Transylvania, which appeared in 2 vols. folio, 1630, a smaller work having appeared ten years before. It consists of thirty-five books, the first four being an explanation of the rest; then follow six books on philology; ten on speculative, and four on practical philosophy; three on speculative, and four of practical photosophy; three on the mechanical arts; and five on history, chronology, and miscellaneous topics. At Basel, in 1877, in 2 vols. folio, appeared the "Lexicon Universale" of Hoffmann, followed by a supplement of the same extent in 1883. the two being incorporated in four vols. folio, 1698. The dictionary form which was introduced by Hoffmann's work is that which has since been generally adopted in encyclopædias. It doubtless suggested the first English work of this kind,—the "Lexicon Technicum, or Universal Dictionary of the Arts and Sciences," by Dr. J. Harris, 2 vols. folio (London, 1706-10). A supplementary volume was afterwards added. It enjoyed great popularity till the appearance of Ephraim Chambers's Cyclopædia, in 2 vols. folio, in 1728. This presented a marked improvement upon its prede-cessors, and by an elaborate system of cross refer-ences, it was attempted to connect the various articles together, so as to form parts of various wholes. "No one," says the author, "seems to have perceived that one," says the author, "seems to have perceived that a dictionary is in some measure capable of the advantages of a continued discourse; and therefore we see nothing like a whole in what has in this sort been done." It was long nounter and a new things of the sort been done." It was long popular, and a seventh edition, in 4 vols. folio, appeared in 1778-85. Various other works of this kind were published before the end of this century, but the only one demanding particular notice is the "Encyclopædia Britannica," the first edition of which was published in 3 vols. 4to, Edinburgh, 1771. The fourth edition of this work appeared in 1810, in 29 vols., and the fifth and sixth, which were mere re-The fourth ection of this work appeared in 1810, in 20 vols., and the fifth and sixth, which were mere reprints, were followed by a supplement in 6 vols., in all classes of persons. It is divided into two parts of one volume each, the one for history and geography. In 1830-43; and the eighth and last in 1852-60. Dr. dhanbers's Cyclopædia, or New Universal Dictionary of Arts and Sciences," extending to 45 vols. 4to (1802-19). Of the other encyclopædias, may be mentioned the "British Encyclopædia," 6 vols. 4to, 1810-29, by John Wilkes; "Pantologia, or New Dictionary of Arts and Sciences," 12 vols. 8vo, 1816; Miller's "Encyclopædia Ludmiensis," 24 vols. 8vo, Edinburgh, 1816; "Oxford Encyclopædia," 10 vols. 4to, 1816; "Encyclopædia Poythensis," 2nd edition, 1816; "Encyclopædia Poythensis," 2nd edition, 23 vols. 8vo, 1826-23; "Partington's British of the third, 25 (from 0 to Phy), making in all 122 ros principles.

Oyclopædia," 10 vols. 8vo, 1833-36, in four divisions, of Arte and Sciences; Biography; Literature, History, Geography, Law, and Politics; and Natural History. In 1818 was begun the "Encyclopædia Metropolitana, or Universal Dictionary of Knewledge," on an original plan, comprising the twofold advantages of a philosophical and an alphabetical arrangement. The plan is by Samuel Taylor Coleridge, and is explained in his article "Method" prefixed to the work. The in his article "Method" prefixed to the work. The matter is arranged in four divisions:—1. the Pure Sciences; 2. the Mixed and Applied Sciences; 3. the Biographical and Historical articles; and 4. the Miscellaneous and Lexicographical articles. The work was completed in 1846, and extended to 25 vols. Ato; and since that time most of the larger articles have and since that time most of the larger articles have been reprinted in a small cabinet form. The plan of this work has been found to be too philosophical for practical purposes. The "Edinburgh Encyclopadia," edited by Dr. (now Sir David) Brewster, was com-menced in 1810 and finished in 1830, in 18 vols. The "Penny Cyclopadia" of the Society for the Diffusion of Useful Knowledge was begun in 1833 and com-pleted in 1843, in 28 vols. Three volumes of supple-ments were subscentily added. This work wheat ments were subsequently added. This work when it appeared was remarkable for the talent displayed in its production, and for its cheapness. The articles were all compiled from original sources, and the total expense for literary labour alone is said to have amounted to £45,000. The "National Cyclopædia," in 12 vols. 8vo, 1847-51, was an abridgement of the "Penny Cyclopædia." Perhaps the most objectionable feature in the "Penny Cyclopædia" was the too much space allotted to natural history subjects for a work of general reference. This has been remedied in the "English Cyclopædia" of Mr. Charles Knight, a work based upon the "Penny Cyclopædia," but divided into four distinct parts, any one of be purchased separately:—I. Arts and Sciences, in 8 vols.; 2. Natural History, in 4 vols.; 3. Biography, in 6 vols., and Geography in 4 vols. This publication was begun in 1853 and completed in 1861, and it may well be said to be "a really great and trustworthy work of reference." The Messrs, Chambers, of Edinard by the reserve burgh, have very recently brought out an encyclopedia based upon the last edition of the German "Conver-sations Lexikon." It extends to nine volumes. Based sations Lexikon." It extends to uine volumes. Based upon an earlier edition of the same work is the "Encyclopædia Americana," a popular dictionary of the arts, sciences, literature, history, politics, and biography, &c., edited by F. Lieber, in 13 vois. Svo., Philadelphia, 1829-33, with a supplementary volume in 1848. The "Popular Encyclopædia," 7 vols. 8vo., Glasgow, 1841, is little more than a reprint of this work. The "New American Cyclopædia," edited by George Ripley and Charles A. Dana, in 8vo., has recently been completed. Dr. Lardner's cyclopædia does not properly belong to this class of works, being does not properly belong to this class of works, being does not properly belong to this class of works, being a collection of independent works connected together by nothing but the title.

Lastly, among English works of this class, we would allude to the present,—"Beeton's Dictionary of Universal Information," a work which, while not attempting, like some of the others, to give learned and elaborate treatises on the different subjects, aims especially at being accurate and practically useful, a book for every day and everybody, and withal at such a price as to render it accessible to

Ato vols. The most pepular of all encyclopedias, and remarkable as being the first that attempted to popularize this class of literature, was the "Conversations-Lexikon," projected by Mr. Brockhaus, the publisher, in Leipsic, and first published there in 1812. It has since gone through a number of editions, the last of which, the tenth, in 15 vols., having appeared between 1851 and 1855. It has been translated into nearly all the languages of Europe, and, even when not translated, it has been largely adopted, or its plan carried out, by works of a similar kind. An abridgement of this work is published under the title of "Kleineres Brockhaus'sches Conversations-Lexikon für den Handgebrauch," wois, 1854-56. The more notable den Handgebrauch," 4 vols., 1854-56. The more notable of the other German encyclopædias are Meyer's "Grosse of the other German encyclopædias are Meyer's "Grosse Conversations-Lexikon für die gebildeten Stünde," in 38 vols. 8vo, Hildburghausen, 1840-52, with a supplement in 6 vols. 1853-55, and 8 volumes of plates; Pierer's "Universal Lexikon der Gegenwart und Vergangenheit, oder neuestes encyclopädischen Wörterbuch der Wissenschaften, Künste und Gewerbe," third edition, 34 vols. 8vo, Altenburg, 1840-46; "Oesterreichische National Enclyopädie," 6 vols. 8vo, Vienna, 1835-37; "Conversations-Lexikon der neuesten Literatur, Völker, und Staatengeschichte," 2 vols. 8vo, Leipsic, 1841-45; "Allgemeine Real Encyclopädie, oder Conversations-Lexikon für das Katholische Deutschland," by Dr. W. Binder, 12 vols. 8vo, Regenburg, 1846-50; and Dr. W. Binder, 12 vols. 8vo, Regenburg, 1846-50; and Herzog's "Encyclopadie für Protestantische Theologie und Kirche," 10 vols. 8vo, 1835-59. In France, the first volume of the celebrated "Encyclopedie, ou Dictionnaire Raisonné des Sciences, des Arts, et des Métiers," of Diderot and D'Alembert, appeared in 1751, and the seventeenth and last of the original series was pubseventeenth and last of the original series was pub-lished in 1765, 11 vols. of plates being added to the text, of which the first was published in 1762, and the last in 1772. A supplement was afterwards added, consisting of 4 vols. of text and one of plates, 1776-7. It is said to have been founded upon an unpublished French translation of Chambers's Encyclopedia, undertaken by an Englishman of the name of Mills. It numbered among its contributors writers of high name, as Voltaire, Rousseau, and others; but they were nearly as volume, houseau, anothers; but they were trary all persons holding very sceptical views on all religious matters. It soon became very popular, and various editions of it were afterwards published in France and other parts of the continent, and its principal writers other parts of the continent, and us principal writers came generally to be known as the Encylopédists. 'It was followed by another work of still greater extent, the "Encyclopédie Méthodique," begun in 1781 and not finished till 1832, comprising 201 vols. 4to, including 47 vols. of plates. Each science or art is treated separated in the statement of the stateme rately in a distinct volume or volumes; so that, in fact it forms a series of dictionaries on special subjects (48 in all), rather than an encyclopædia proper. The first edition of the Encyclopédie Moderne, ou Dictionnaire abrogs, des Sciences, des Lettres et des Arts, &c., par une Société de Gens de Lettres," was published in 28 vols. 8vo, with 2 vols. of plates; Paris, 1823-32. A third edition of this work was pub-blished in 27 vols., with 4 vols. of plates, in 1852-57, bissed in 27 vois., with 4 vois. of piates, in 1852-57, to which a supplement is in course of being added, the 10th vol., published 1961, coming down to the end of O. A useful work of this class is the "Encyclopédie des Gens du Monde," in 22 vols.; Paris, 1833-44. The French have also a "Dictionnaire de la Conversation des Gens du Monde," in 22 vois.; Paris, 1833-44. The French have also a "Dictionnaire de la Conversation et de la Lecture," in 68 vols. (Paris, 1839-51), of which a new edition begun in 1851 is still in progress, and a "Conversations Lexicon," founded upon the last edition of the German work of that name. Based upon the German: "Conversations Lexikon" are the "Enciclopedia Española," begun at Madrid in 1842; the "Biblioteca universal de Instrucciou," Barcelona, 1842; the "Almennyttight Dansk Konversations-Lexikon," by Larsen. Copenhagen, 1849; the "Svenskt Konversations-Lexikon," by Larsen. Copenhagen, 1849; the "Svenskt Konversations-Lexikon," by Larsen. Copenhagen, 1849; the "Svenskt Konversations-Lexikon," by Larsen. the "Almennyttight Dansk Konversations-Lexikon," by P. Larsen, Copenhagen, 1849; the "Svenskt Konversations-Lexikon," Stockholm, 1845; besides others in Holland, Russia, Hungary, &c. At Turin, a "Nuova Enciclopedia popolare Italiana," in 4to, was begun in 1856. Those encyclopedias that we have noticed have been more or less universal in their character and aim; but there exists another and also an important branch of this class of works,—those, namely, that are devoted of this class of works,—those, namely, the act worker to separate branches of literature, science, or art. The number of these works is rapidly increasing, and their character improving,—indeed, now there is scarcely a 764

department of human knowledge that has not its dictionary or encyclopædia. As knowledge increases, so must the demand for encyclopædias also increase. As the sphere of knowledge extends, the less able is man, with his limited powers and capacities, to embrace the with his limited powers and capacities, to embrace the whole circle; he must, therefore, have recourse to helps,—to books where he can get what information he wants in a comprehensive and easily accessible form; and to furnish this is the object of an encyclopedia. The importance of this class of works is not yet sufficiently the contract of the co The importance of this class of works is not yet suni-ciently recognized in this country. In Germany almost every family, even among the lower classes, has its encyclopedia. In the words of the editor of "Mac-millan's Magazine,"—"An encyclopedia in any man's house is a possession in itself for him and his family; an encyclopedia chained at Charing-cross for public reference would be a boon to London worth fifty drinking-fountains."

drinking-fountains."

Endemic, endemides, from en, among, and demos, the people), in Med., is a term employed to designate diseases peouliar to a certain class of persons, or to a particular district. Thus ague is an endemic disease in low marshy countries; the goitre in the Aips. They differ from epidemic diseases, which, without reference to locality or class, attack many persons at the same time in the same place, and are contagious; as influenza, scarlet fever, &c.

ENDIVE. (See CICHOBIUM.)

ENDOCARP, en'-do-karp (Gr. endon, within; karpes, a fruit), in Bot., the inner layer of the pericarp of a fruit. In certain fruits it is remarkably hard, and is termed the stone or putamen. In the almond the endocarp forms a thin woody shell; in the apple it is the core containing the seeds, and in the orange it constitutes the thin membranous partitions which divide the

pulp into separate portions. (See FBUIT.)
ENDOGENOUS PLANTS, or ENDOGENS, en-doj'-e-mus
(Gr. endon, within; ginomai, I am formed), plants
having stems which increase by the addition of new matter within. De Candolle's class Endogenæ corresponds with Monocotyledones of most botauists, and its essential characters are given in this work under

the latter head.

ENDONOSE, en-dos'-mose (Gr. endon, within; oemose, impulsion), a term originally applied by Dutrochet to the transfusion of gaseous bodies or liquids through membranous substances either of an animal or vegetable origin. He found that if two fluids of unequal density are separated by a membrane, the denser fluid will attract or draw to it the less dense. When the attraction was from without inwards, he called it endosmose; when from within outwards, he called it exos-mose. In spinals and vegetables this remarkable action of fluids performs a very important part. Upon it depend many phenomena connected with the circula-tion of the blood in animals and the circulation of the sap in vegetables. The substance contained within the membranous covers of the cells of plants is denser than the fluids without; hence a process of endosmose takes place by which the plant is supplied with nourishment from the soil. The bursting of some seeds and fruits depends upon endosmose; and some of the entozoa appear to exist by its action.

ENDOWMENT, en-dow'-ment (from Fr. endouairer, to endow), in Law, is the bestowing or assuring of dower upon a woman. It is sometimes used metaphorically upon a woman. upon a woman. It is sometimes used metaphorically for the settling a provision upon a parson, or building a church or chapel; and the severing a sufficient portion of the tithes, &c., for a vicar, towards his perpetual maintenance when the benefice is appropriated. ENYMON, en-dim'e-on, in Bot., the Blue-bell, a gen. of plants of the nat. ord. Likiacses. E. nutane is the species which adorns the woods and thickets of this country. It of downs are negality blue, weak which

country. Its flowers are usually blue, rarely white.

ENEMA. (See CLYSTER.)
ENEMES, ADERLING TO THE QUEEN'S. (See TREA-

SON.)
ENFIELD RIFLE. (See RIFLE.)
ENFILADE, en-fe-twid' (Fr.).—When the line of fire from artillery or musketry is directed along the front of a body of troops drawn up in line, instead of against it, or, so as to sweep the interior of any part of the defensive works about a place, or a trench in siege-works, from one end to the other in the direction of its length, it is called an enfillading

through the embrasure. Explushage, an(g)-flur-ashe (Fr.), a process for extracting the acouts from flowers by absorption. We are filled with flowers, and allowed to remain for a fat are filled with flowers, and allowed to remain for a time, varying from one to six days. The grease gradually absorbs the scent, the flowers being renewed from e to time throughout their period of blooming. The scent is afterwards separated from the grease by soak ing it in strong spirits of wine. Sometimes wire frames

covered with cotton cloths imbued with fine olive-oil are used instead of glass. In this manner the most delicate odours are extracted from flowers.

ENFRANCHISEMENT, en-frun'-tshiz-ment (Fr. fran-chise, freedom or right), is the act of admitting a person to certain privileges or liberties; as where one receives the freedom of a town corporate. In Law, the enfran-chisement of a copyhold is its conversion into a freehold by agreement with the lord of the manor. By 15 & 16 Vict. c.51, after the next admission subsequent to 1st July, 1853, either the lord or the tenant may require and compel the enfranchisement of the land in consideration of a gross sum or of an annual rent, fixed either by mutual agreement or by valuators and an umpire under the direction of the copyhold com-

missioners. (See Copynotic).

Engine, cn'-jin (Lat. ingenium, a contrivance), a term applied in Mech. to any compound machine or instrument composed of various parts, and intended to produce some effect by mechanical force; such as a pump, a windlass, &c. Some engines are distin-guished by connecting the word engine with the purposes for which they are used; as, steam-engine, fireengine, &c. Battering-rams, and machines of the same class, are called military engines.

class, are called military engines.

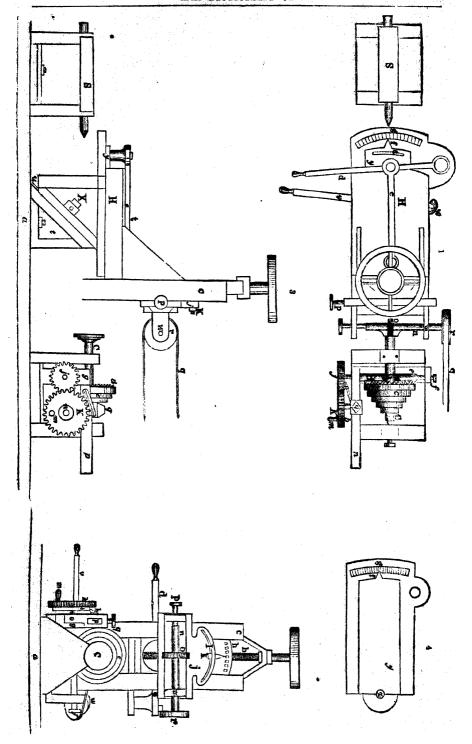

ENGINE, AIR. (See AIR-ENGINE.)

ENGINE, FIRE. (See FIRE-ENGINE.)

ENGINE, STRAM. (See STRAM-ENGINE.)

ENGINE, CUTTING.—A new and useful improvement of a cutting engine, or machine for dividing and cutting the teeth of cog, wheels, has been invented by an American mechanist, Mr. J. Gaume, of Cincinnati, Hamilton County, Ohio. In the accompanying woodcuts, fig. 1 is a plan, fig. 2 a side elevation, and fig. 3 a front view of the machine. The same letters indicate like parts in all the woodcuts. The leading indicate like parts in all the woodcuts. The leading object of this invention is to adapt the common lathe, by the addition of certain parts, to the cutting of cogwheels, chiefly for the use of small shops and esta-blishments, where a latbe and cutting engine are only occasionally used. The principle of the first part of this invention consists in adding to a lathe, and in combination with the mandrel thereof, a puppet made in two parts for carrying the cutter, the lower half to be attached in the usual manner to the bench, and connected with the upper one by an inclined plane, that the upper part may slide on the lower one at an angle of forty-five or any other number of degrees, for angle of forty-nee or any other number of degrees, for the purpose of carrying the cutter or curr over the wheel in the operation of cutting the cogs of bevel wheels. The second portion of this invention consists in combining with this puppet the cutter-frame, which carries the spindle of the cutter or curr by means of an adjustable horizontal slide, on which the cutteran adjustable nonzontal since, on when the cutter-frame moves to and fro to carry the cutter over the wheel in which the cogs are to be cut, the said slide being a plate with dovetsil or other formed edges, embraced by or embracing the cutter-frame, and attached at one end by a fixed bolt to the top plate of the puppet, and at the other by a serew bolt that attached at one end by a fixed bolt to the top plate of the pupper, and at the other by a serow bolt that passes through scurved slot, whereby the cutter-frame may be made to carry the cutter in its horizontal motion diagonally with the axis of the mandrel for the cutting of diagonal cogs. The spindle of the cutter or curr having its bearings in an adjustable slide that moves at right angles to the mandrel, to bring the

cutter over the axis of the mandrel (the bed of the slide being connected with a vertical slide in the cutterframe to adapt the cutter to wheels of different diameters) by means of a fixed bolt on one side, and a screw bolt passing through a curved slot on the other, that the axis of the cutter may be placed at any angle with a vertical line. The third part of the invention relates to the method of dividing the cogs, and consists in placing the index-wheel on a slide, that it may be divided to whale of any dealed, adjusted to a wheel of any desired number of cogs on an arbor that communicates by a screw or its equivalent to the mandrel which carries the wheel to be cut, so that by merely changing the wheel on this arbor, a single division-index may be used for the outling of any desired number of cogs. The fourth part of the invention consists in combining the dividing apparatus with the mandrel of a lathe, by means of cogs in the pulley of the mandrel, or on the mandrel, the dividing apparatus being sarranged that it can be thrown in apparatus being so arranged that it can be thrown in and out of gear. In the annexed engravings a repre-sents the bench of the lathe, C the mandrel with its set of cone pulleys (c), the face of the larger one of which is a crown cog-wheel (d), the cogs of which engage with the threads of an endless screw on arbore: the threads of this screw are shown by dotted lines in the plan, fig. 1. One end of the arbor runs on the point of a pivot screw (f), and the actor runs on the point of a pivot screw (f), and the other has a long journal that runs in a box in a standard (g), attached to the bench or the puppet-head of the mandrel; so that when the rear end is liberated from out of the cogs of the crown wheel, the mandrel may be used for turning the cog-wheel. In this way there is no danger of the wheel not being properly centred. When the of the wheel not being properly centred. When the wheel is to be cut, the arbor e is properly mounted, and its outer end is adapted by a collar and nut to receive a spur-wheel (j), of any desired number of cogs, which take into the cogs of the wheel K, one face of which is provided with the division-plate or index (b), and the other end with a handle (m) for turning it. This wheel is fitted to and turns on a stud-pin (n), projecting from a late (a) that slides on an arm (a) of it a standard (a) a plate (o) that slides on an arm (p) of the standard (g), that it may be set to the proper pitch-line of a wheel of any desired size on the arbor e, and there held by a screw (g). A spring-point or catch (r) is used to catch in the notches of the index or division-plate (b). From the preceding remarks it will be seen that with any given size of wheel on the arbor e, the number of cogs to be size of wheel on the arbor c, the number of cogs to be out may be varied by the motions of the dividing or index wheel, as in the ordinary dividing-engine, and that by changing the wheel on the arbor c, any variation can be given to these divisions. The wheel having been turned, and the dividing apparatus put in connection, the centring puppet-head (s) of the lathe is thrown back, and the extra puppet (t) is secured in place on the bench. This puppet is made in two parts (t, t), connected together by s dovetail or other slide (u) at an angle of 45°, or any other number of degrees, with the plane of the bench. The lower half (t) is secured to the bench, and the other (t) can be made to slide on it by means of a handle or lever (v), that turns on a fulcrum-pin (w) attached to the lower half, and connected with the upper half is in a plane parallel with the mandrel, and has a dovetail slide (y) connected with it at the forward end by a fixed bolt, a (see fig. 4, which is a plain view of this part), and at the other end by a screw bolt (a), that passes through a curved slot (see the dotted line) in the top plate, so that any horizontal inclination desired may be given to this slide, which is embraced by the bottom plate of the contraction of the supper to this slide, which is embraced by the bottom plate of the supper half is not be wall. cut may be varied by the motions of the dividing or to this slide, which is embraced by the bottom plate (H) of the cutter-frame (c), and which can be made to slide thereon by a handle or lever (d), that turns on a fulrum-pin attached to the puppet, and con-nected with the cutter-frame by a joint link (e), so that by the motion of this lever the attendant carries the cutter to and fro horizontally over the edge of the wheel to be cut, for cutting spur cogs in a direction parallel with the axis of the mandrel, or a curculon paramet with the axis of the mandrel, or inclined therewith as the slide may be set, to be indi-cated by a pointer (f) on the cutter-frame, and an index (g) on the top plate of the puppet. But when the machine is used for cutting the cogs on bevel wheels, then the cutting-frame is carried by aliding the upper part (t) of the puppet-head on the lowe

part, fig. 4; the inclination of this slide determining the bevel of the cogs cut. The forward part of the cutter-frame has a plate (h) that slides in it vertically by currer-reams has a plate (a) that slides in it vertically by means of a seriew (b), to adapt the cutter to any desired diameter of wheel to be cut; to this is connected another plate (j), that turns on a bolt, and further secured by a screw-bolt (k) that passes through a curved slot (l), by means of which the plate (j) may be turned on the fixed bolt as a centre, to give any desired inclination to the axis of a cutter; and this last-named plate is provided with dovetall ways, in which slides the cutter-carrier (m), which is a frame in which are the bearings of the spindle (n) of the cutter (o), so that this may be regulated endwise by a set screw (p). The cutter is rotated by a belt (q), that passes from any prime mover over a pulley (r) on the spindle. From the foregoing it will be seen that the cutter can be adjusted in any direction relatively to the axis of the mandrel that carries the wheel to be cut; and that, by means of one of the handles or levers, the cutter-frame can be moved to and fro to cut the cogs by sliding the cutter-carriage on the puppet in a hori-zontal plane parallel with the axis of the mandrel, which, by the adjustment of the ways or slide on the which, by the adjustment of the ways or side on the puppet, may be adjusted to move in a vertical plane projected from the axis of the mandrel, or at any inclination therewith, to cut oblique coga; or by means of the other handle, that the cutter-frame may be made to move with the upper part of the puppet on an inclined plane, to cut the cogs of bevel cogwheels. It will be obvious, from the plan of the above that the plan of the junction of the two halves of the puppet may be made at any inclination desired, to suit the bevel of the wheel intended to be out. This machine may be composed either of a single lathe, or of a complicated one, of any desired dimensions, and nothing need be added to it but a side-coupling to form the division. Its advantages are:-1. Turning the wheel on its points; it is thus cut on these same points with the axis, the length of which may be placed on the lathe; likewise by turning the wheel on the flat side, the hole in the centre and the circumference are cut without its being removed. 2. This machine can cut a machine on the circumference obliquely, to the right or left, with any desired incli-nation, and also the same with regard to the wheel on the side. 3. The wheel can be cut at any angle of 45°. This machine can take the place of, and even offers advantages over, the "Great Platform." It can be constructed of any dimensions, always being able to out the wheel, which can be turned on the lathe, even should it be fifteen feet in diameter. This machine can be adapted to a lathe placed upon a wooden bench, with only one hundred and fifty pounds weight of additional castings. The division extends to all numbers with the greatest precision.

ENGINEERING, en-jin-eer-ing (Fr. ingénieur, an engineer). Strictly speaking, the term engineering sbould only be applied to the art of making machines, and using them for the performance of any work; but its signification has been extended to comprehend the art of raising constructive works for civil or military purposes. Engineering, in its extended signification, may be considered as being divided into two distinct departments,—civil engineering and military engineering. A notice of the various duties and employments the civil engineer will be found in the following article. The military engineer is more particularly employed in designing, planning, and constructing works of defence and fortifications, as well as the siege-works, trenches, approaches, and mines of an attacking force investing a fortified town. He must accounting force investing a fortined town. He must also understand and be practically acquainted with the construction of the various kinds of bridges in use for the transportation of troops across rivers (see BRINGE, MILITARY), and the method of taking a survey of any tract of country by measurement or transpolation in an acquesta manage or account. by mere inspection, and judging the heights of hills and the distances of conspicuous objects from point to and the distances of conspicuous opects from point to point. In the English service these works are executed by a body of officers and men especially educated and enrolled for the purpose, and called the "Royal Engi-neers" or "Sappers and Miners." In warfare, the engineers are intrusted with any work of demolition 767

necessary to cover the retrest of an army, such blowing up bridges, &c.; and in forcing open the ga of a fortress, the hazardous enterprise of fixing to powder-bags and attaching the sancisson, or laying the train required to cause their explosion.

ENGINEERING, CIVIL (Lat. civilis, of or belonging to a state).—There are many duties and branches belonging to this important profession, which, in many respects, is allied to that of the architect, although this great distinction lies between the constructive works of each; namely, that the buildings raised by the engineer are works of great solidity, and of a use-ful nature, especially designed for the promotion of commerce, while those of the architect are structures of ornamental character and artistic design, of which the former, except in rare instances, are necessarily devoid. Among the chief duties of the civil engineer, devoid. Among the cnier duties of the civil angineer, is the construction of roads and great highways, aqueducts and canals, with all the necessary accompaniments, such as locks, lockgates, culverts, and bridges. All such structures as breakwaters and lighthouses, which are buildings requiring great strength and solidity in the construction of their masoury and foundations, and the formation of huge masses of earth, thrown up as embankments, to protect countries that are below the level of the sea from inundation, or low meadow lands from being flooded by rivers that are subject to sudden and rapid increase from heavy rains, come within the province of the civil engineer. He also constructs docks for the reception of shipping, quays, reservoirs, and watercourses for supplying towns with water brought from a disand fenny districts, and irrigates dry soil requiring moisture to render it productive, by various artificial means. Railroads, with their deep cuttings, immense embankments, lofty viaducts, dark tunnels, and roadways sometimes carried for miles on arches of brickwork,-their iron girder and other bridges, of enormous who the civil engineer. The formation of artificial harbours by throwing out piers and jettles; and the clearage of natural harbours from all obstructions, such as sunken rocks and sandbanks; and the construction of the great sewers and drains that run in every direction under our large towns and cities, all come under his care; and, in addition to this, he has to superintend the construction of the shatts and machinery of mines and coal-pits, to insure safety to the miners in their ascent and descent, and to secure proper and thorough ventilation in all parts of the mine. Another great branch of civil engineering is the manufacture of massive machinery, such as pumps, hydraulic and lever presses, looms, and steam-engines of all descriplever presses, looms, and seemi-rightee or an descrip-tions, whether they be locomotives, or for vessels, or for setting machinery in motion. In short, the civil engineer seeks to adapt the mechanical powers and their appliances, and bring them into such forms and combinations that they may furnish the means of saving the expenditure and waste of animal strength saving the expenditure and waste of animal strength and manual labour, and thereby cause the work to be done at a cheaper rate, and in a more efficient manner. It is only within the last three centuries that the professions of architect, painter, sculptor, and engineer, whether civil or military, have become separate and distinct callings. Those of the civil and military engineer have chiefly been elicited and established by the invasion of gunnowder and cannot. blished by the invention of gunpowder and cannon, which necessitated the employment of peculiar skill and close study in planning and constructing the works of defence that surround any place of importance; and the requirements of commerce, which has long since demanded, and still demands, canals, reads, resilvoads, and motive power beyond the constant con-trol of the winds and waves, for the conveyance of merchandise by land or sea. Although we may con-sider Archimedes as the first engineer of whom meation is made in history, in memorable connection with appliances of the lever and other mechanical powers, yet the early nations of the world, especially the Bgyptians, who raised and fixed in their present posireared the might monoliths known as Pompey's Pillar and Cleopatra's Needles, must have been pos-

sessed of engineers of to ordinary mental capacity. Sessed of engineers or no ordinary mental capacity. The blocks that form the Cyclopean walls of Tiryns and Mycaus, the marble columns and the temples of the Greeks, the sewerage and aqueduots of Rome, the underground structures for the drainage of the Assyrian city Nimroud, the canal of Xerxes that separated Mount Athos from the mainland, and the remains of those found in various parts of Egypt, Assyria, and the East, choked with sand and rubbish, all tell us of the magnificent schemes that the engineers of antiquity designed and carried out, whose names are lost to us, and whose works have been almost entirely destroyed. or at least rendered useless by neglect and the lapse of time. Among the engineers who flourished before the Christian ers, Archimedes, who so skilfully conducted the defence of Syracuse, is the carliest on record, unless we consider Hiram, the clever Syrian artificer, who sided Solomon in the building of the Temple, as an engineer, as he doubtless was, and more than this, the best of that period that was to be found through-out Palestine. The writings of Vitruvius prove him to have been employed in the structure of military to have been employed in the structure or mintary machines and works of defence, as well as in architecture, and the building of mills and manufacture of pumping-engines, and other works of utility for agricultural and commercial purposes. In the middle ages, and even in later periods, we still find the professions we have mentioned above combined in one person; for the eminent architect Brunelleschi, and Michael Angelo, the sculptor and artist, are mentioned as constructing fortifications, and the illustrious painter Leonardo da Vinci rendering an important service in the capacity of engineer by the construction of the first canal lock that was ever used to afford means of communication between waters on different levels. In our own country, the ecclessatics, in whom the greater part of the learning of the times seems to have centered, and who were the most famous architects of their times, as exemplified in the cases of William of Wykeham and Peter of Colechurch, were also the best wysenam and refer of Coleculation, were also the best practical engineers of the day, prior to 1500; and it is towards the close of the 17th century that we find the celebrated architect Sir O. Wren also acting as a civil engineer. Among engineers of the 16th century, Albert Durer, the painter and engraver, may be named, who wrote to some extent on the science of footification, but of this time considerable shill be seen that the science of the science fortification; but at this time considerable skill civil engineering had been attained, both in northern Italy and Holland, where every effort was obliged to be made to secure the inhabitants of these fertile lowland districts from the encroachments of the sea and the rivers, and to render the surplus waters of the country the means of obtaining an easy transit for merchandise and the productions of the soil from one merchandise and the productions of the soil from one point to another. At the end of the 16th century, the profession of the military engineer began to be brought into greater prominence, and to be considered as requiring special qualifications in him who might undertake the office, and Errard de Bar le Duc, De Ville, Pagan, Vauban, Cormontaigne, Coehorn, and Belidor, may be considered as the originators of the modern system of military engineering. In Parket bendor, may be commerce as the originators of the modern system of military engineering. In Eugland, although civil engineers had long been attached to English armies at home and abroad, yet the first smilitary corps of engineers, now known as the Royal Engineers, was not formed until 1787. But prior to this date, the rapid extension of commerce, and the de-mand for improved means of inland communication, had called the peculiar talents of Brindley into active eneration in the formation of the Bridgewater canal. speration in the formation of the Bridgewater canal. At this period, civil engineering began to be considered a distinct profession in itself, of considerable importance in this country, and the Eddystone lighthouse, and the numerous canals, docks, and railway works in every part of the country, and our magnificent iron steam marine, and improved weapons of all calibres, constructed by Smeaton, the Rennies, Telford, James Watt, the Stephensons, Looke, Sir Isambard Brunel and his son, Scott Russell, Armstrong, and Whitworth, and many others, show what marked and rapid process has been made in this branch of science. In and many others, show wast marked and rapid progress has been made in this branch of science. In 1793, a society of civil engineers was formed by Smeaton and others, under the name of the Smeatonian Society of Civil Engineers, and in 1818 the Institution of Civil Engineers was established, and incorporated

by royal charter about ten years after. A person who desires to become a civil engineer, and possesses sufficient attainments to master the necessary subjects, sufficient attainments to master the necessary subjects, should obtain an intimate knowledge of arithmetic and mathematics, trigonometry, statics, dynamics, hydro-statics, and hydrodynamics, mapping, surreying, and mechanical drawing, in order to enable him to con-struct plans and sections of lines of country for canals, ds, &c., and to calculate the cost of materials railroads, &c., sau to calculate the cost of insecriats and labour. He must also be acquainted with the strength and resistance of different materials in different positions and combinations, that he may be enabled to determine the principles of equilibrium in enabled to determine the principles of equilibrium in arches and roofs, the slope and form of his outtings and embankments for railroads, and to resist the pressure of water; and he must also have a knowledge of the mechanical powers and machinery, and the means of applying them. With the theories acquired in the attainment of a knowledge of these aubjects, practice must afterwards be combined; but in addition to practice and theory, good natural capacities and inherent talent of no ordinary nature are indispensable to cause a man to reach any degree of eminence in such a profession as civil engineering.

ENGINEERS, ROYAL CORPS OF, one of the component parts of the English army. It has for its duties the making and defending of all military works, and also the attack of similar works held by the enemy. the attack of similar works held by the enemy. The engineers form one regiment, and, unlike other branches of the army, are in continuous service both in peace and war. They are spread all over the world, and they are intrusted with the construction of all land and sea fortifications. In this work they are often assisted by civilians; but the engineer departoften assisted by civilians; but the engineer department of the country is responsible for the efficiency of the result. The corps of engineers was first formed in 1763, and in 1783 it was made a royal corps. In 1812 several corps of artificers, called sappers and miners, were placed under the engineers. Officers intended for the engineers enter the Royal Military Academy as cadets, and compete for their commissions at various periods. The head quarters of the engi-

neers are at Chatham.

ENGINERS IN THE ROYAL NAVY are those men who attend to the machinery on board the war steamers. When vessels of this kind were first employed, men were obtained from ordinary merchant steamers.
Many changes were afterwards made, and there are
now various grades of engineers in the navy. There now various grades of engineers in the newly. Another are inspectors of machinery, whief engineers, and assistant engineers, the latter class being subdivided into three parts. These are all commissioned officers, and are strictly examined before being admitted. the commencement of this year (1862), the number of naval engineers was reckoned at 1,089, with eight in-

spectors of machinery.

ENGLISH LANGUAGE, ing'-glish, is the vehicle of spoken and written communication between upwards spoken and written communication between upwards of fifty millions of people, and is as heterogeneous in its elements as it is widely extended in its sphere. "Latin, Greek, Hebrew, Celtic, Saxon, Danish, French, Spanish, Italian, German," says M. Müller, in his recent "Leotures on the Science of Language,"—"nay, even Hindustani, Maley, and Chinese words, lie mixed together in the English dictionary." It was long a popular, and probably somewhat partial, whim in this country, that Anglo-Saxon formed at least two-thirds of the sooken and written speech of it. But M. Thommerel spoken and written speech of it. But M. Thommerel has recently carefully gone over the dictionaries of Robertson and Webster, and has established the fact, that Anglo-Saxon stands in no greater a proportion to the words of merely Latin origin than the relation that 13,330 holds to 29,354. Yet the English lan-guage is essentially and truly a Teutonic or Saxon tongue; for it is not the extent of the vocabulary of iongue; for it is not the extent of the vocabulary of a language that gives colour to the title of that language,—it is to the grammar to which the tongue conforms that we must trace its scientific relationship. Now, whatever there remains of grammar in English—and, indeed, it is very little—obviously bears marks of being forged in a Teutonic workshop; and hence the necessity that there is for classifying it as such in the general philology of the world. In tracing the growth of the English language, it is usual to divide its history into the four periods of Anglo-Saxon (449 a.m.—1088)

A.D.), Semi-Saxon (1066 A.D.-1250 A.D.), Early English (1250 A.D.—1550 A.D.), and Modern English (1500 A.D. to the present day). These in their order: to the present day).

The Anglo-Sazza period of the language dates from a time when, in the 5th century, the Teutonic searovers first occupied the southern portion of the island, and drove back its original Celtic inhabitants to the north and west. No sooner had they done this, to the north and west. No sooner had they done this, than they settled in the island, and from that day to this the prevailing tongue of the country has been Anglo-Saxon, or English. This Anglo-Saxon was a Low-German dialect, bearing a close similarity to the old Frisic, which is usually recognized as the parent of the modern Dutch. After long years of social feuds and of national warfare, the absorption by Wessex, or West Saxons, of the various portions of the Heptarchy, in the 9th century, went far to make the ruling speech of the land the tongue of Berks and of Hants, the recognized centre of this clau. This fact not only gave colour to the more refined speech of the Anglo-Saxons, but, in addition to this, the fact of King Alfred, a native of Berks, rising up to be himself such an illustrious ornament to the letters of England, was a an illustrious ornament to the letters of England, was a special literary confirmation of what before had been simply asserted by the sword. When we compare the writings of Codmon, a North Anglian, and the writings of Alfred, two dialectical peculiarities at least seem at that early period to have prevailed in the island. There was the Northern or Anglian, which prevailed from the Humber to the Firth of Forth, and the Southern or Saxon one, which was spoken from the Humber to the English Channel. Now, which of those Angle-Saxon dialects entered specifically into the formation of the English tongue? Two answers have been given to this question by competent scholars. The one, that the classical Saxon of Wessex gradually gave way to another dialect, -that of the Midland counties; the other, that we must look for the real ground-work of our tougue in the gradual coalescence of all the leading dialects of England.— (See Sir Francis Madden's edition of Layamon's Brut, 1847.) The latter view, we confess, appears the more likely. main peculiarity of the tongue of the island at this early period was, that the influtives were still in an; the substantives, adjectives, pronouns, and articles, were declined like the Latin; and the plural was unlike the singular: in other respects it differed much less from our modern vocabulary than one might at first sight

Suppose.

The Semi-Suxon period was a transition era, and, like every era of the kind, one of contusion and one of promise. The monks were, of course, the learned class promise. and the medieval Latin in which they performed their Ave-Murias and their Paternosters, when they attempted to write their mother-tongue they fell into the grossest mistakes. The "Saxon Chronicle," 1173, and Layamon's "Brut" (about 1200), afford abundant specimens of this slip-shod style of Anglo-Saxon, and it is abundantly evident, from an examination of the inflections and genders of the language, that it was undergoing at this time a thorough breaking up. En is constantly substituted for on in the plurals of verbs; the final a is often discarded, weak rectevies constantly. the final e is often discarded; weak preterites occa sionally take the form of strong ones, and there is a marked uncertainty in the government of prepositions. There is another curious feature observable in the Anglo-Saxon of this time, - that although its date makes it reach a century or two beyond the Conquest of 1066, it nevertheless exhibits but few traces of Norman French. In that curious old poem which has just been referred to, the "Brut," there are not more than fifty French or Latin words in a composition of 32,000 lines! Norman French might be the language of the

709

new word attached to the original one, whereas the old Saxon tongue, like a genuine element of the Teu-tonic, always expressed such ideas by a modification tonic, always expressed such ideas by a modification of this word. In the admirable poem of the "Owl and the Nightingale," written probably towards the end of the 13th century, the French language appears as a decided element in its vocabulary. It has likewise become, by the time we reach Chaucer, Gower, and Lydgate, a component part of English speech. And it is obvious that this modification was effected durch was through the likeway are and decided the second which was much more through the literary regard which was engendered in the breasts of those old poets for the French Fabliaux, and such like writings, than from any superior respect which they reluctantly paid to the speech of their Norman masters. Yet certain poets still clung affectionately to the old tongue, and in "Piers Plowman," and in a few others, we see examples of writers who still found the Anglo-Saxon sufficient for all their wants. The beautiful old ballad of the "Nut-brown Maid" (about 1500) is so modern in its style that it is difficult to believe it to be so ancient by a century at least. In the southern part of Scotby a century at least. In the southern part of Scotland again, and particularly the Anglian counties lying south of the Forth, the language of the people was to all intents and purposes identical with the language of the extreme south. And it is to be noted, in illustra-tion of this remark, that Barbour, a Scottish contemporary of Chaucer, wrote purer English than Chaucer did; that is to say, his poems were much freer from the foreign element of Norman-French. The northeastern dialects of Scotland have always presented a stumbling-block to the ethnologists; for it is unquestionable that the inhabitants of those counties speak a language which, in its grammar at least, is very nearly akin to that of Norfolk and Yorkshire. Yet in the vocabulary of the people, there are a considerable number of words of Norse or Scandinavian origin. The existence, during the 11th century, for a period of thirty years, of a Norwegian kingdom under the sea-rover Thorfion, in the extreme nor-h-east of the island, might partially account for this Norse element in the speech of the country. But how are we to account for the existence of an Anglo-Saxon grammar north and east of the Forth, or even of the Tay? for it is well enough known that the Norse languages it is well enough known that the morse amiguações are all widely diverse in their grammar from the Eaxon. No satisfactory answer has yet been given to this question; nothing but vague theories indeed have been formed regarding it. The close likeness of the two tongues to the north and south of the island did not last long after the wer of independence. So early not last long after the war of independence. So early as Dunbar, the best Scottish poet before Burns, pedautic Latinisms had usurped the place of pure Angle-Saxon, and in his best poem, the "Daunce," the striking personifications abound with what were then considered as barbarisms.

In the Modern English period of the language, it was to a great extent perfected as to its granmar, its still deficient as to its vocabulary. Of course the rules and forms of the grammar had still to be rendered workable and delicate by the use which great practice can alone communicate. It is to be observed, however, that it was much more in the ease and dexterity which the old forms of speech received, that this modern period is distinguished, rather than in any new modifications effected upon the grammar itself. Of course the additions which have been made to the English dictionary since the beginning of the 16th century have been immense,—a process which still goes on; but the effects of change on the glossary of a tongue are merely secondary. The changes, accordtongue are merely secondary. The changes, accordingly, which it has since undergone, are merely changes in style, or in the variety of modes in which different individuals express themselves. The English language is worthy, by its remarkable combination of force, precision, and fulness, of being, as it is already, the speech of nearly all the free nations of the world. If it cannot boast of native purity, it can at least boast of what is better than purity in a language,—the strength and copionsness, the delicacy and grace, the refinement and tenderness, in which its glossary abounds. If it is Teutonic in its stem, as the single s in the third person singular of the present indicative lines! Norman French might be the language of the court; it certainly was not the language of the people. The Early English period, again, of the language is worthy, by its remarkable combination of force, the Early English tongue now asserts itself throughout; yet it is still struggling to become. In the first place, it contrived gradually to get rid of all Anglo-Saxon inflections, particularly in the substantives and adjectives; the vowels a, a, u in final syllables are all represented by e, and the final no of the inflinitive has already begun to disappear. It constantly prefers to express themselves. The English language is worthy, by its remarkable combination of force, precision, and fulness, of being, as it is already, the troughout; yet it is still struggling to become. In the first place, it contrived gradually to get rid of all the substantive and adjectives; the vowels a, a, u in final syllables are all represented by e, and the final no of the inflinitive has already begun to disappear. It constantly prefers to express themselves. The English language is worthy, by its remarkable combination of force, wor

## English Literature

Rurope.—Ref. The Origin and History of the English Language, by George P. Marsh, 1862; and other very accessible works are those of Craik, Spalding, and Latham.

ENGLISH LITERATURE is modified in a highly important manner by the history of the English people. Bras of great literary progress have always been found to succeed those periods of the nation's history characterized by important social changes, and sometimes by national revolutions. The literary named of England may be conveniently arranged into three periods:—1. That antecedent to the Norman Conquest; 2. that extending from the Norman Conquest to the English Reformation; and 3. from the English Reformation to

the present day. These in their order.

1. The time preceding the Conquest has a literature composed in three distinct languages, and possessing merits of a highly important character. First, there is the Celtic, spoken by the Northern Scots, the Irish, and the Welsh. The "Annals of the Four Musters," compiled by Tigernach, records the authentic doings of the Irish people so early as the fifth century. No other nation of modern Europe can make a similar Then there are the Scottish Ossianic poems, boast. Then there are the Section Visionic Person, which, if they were gennine, would lead back the reader to the third century. Among the Welsh people, again, their triads are said to extend as far back as the sixth century, although nothing very authentic can be learned of the exploits of the famous Welsh prince Arthur of the Round Tuble, or of the enchantments of the renowned magician Merlin. The cultivation of Latin nowned magician Merlin. The cultivation of Latin literature in this country succeeded the introduction of Christianity into it. St. Ninian establishing himself at Whithorn, tried to convert Scotland late in the fourth century; St. Patrick made a similar attempt in Ireland in the fifth century; and St. Augustine laid the foundation of the Anglo-Catholic church late in the sixth century. Literary effort soon followed, and we meet as first in this honourable list the names of Alauin of Frigara and of Red. The "Clearage" we meet as first in this bonourable list the names of Aleuin, of Erigena, and of Bede. The "Gleeman's Song," the "Battle of Finnesburgh," and the "Tale of Beowulph," are the only stories of a Homeric cast which the Anglo-Saxon people possess. The latter, in of Beowulph," are the only stories of a moment can which the Anglo-Saxon people possess. The latter, in particular, resembles closely, in some of its vividly picturesque touches, the old liad of Troy. Doubless such remarkable religious poems as those of the monk Caedmon deserve to be mentioned in any summary of the literary history of England. Yet the Anglo-Sayon people were comparatively poor in poetry; but they were eminently simple and direct prose writers. Portions of the sacred Scriptures, Anglo-Saxon chronicles, sermons, glossaries, grammars, geographies, medical works, and dialogues, in their tongue, were all composed by their leading writers, Aldheim, Bede, and Alfred. It was chiefly through the influence of the latter, who discarded Latin in all his communications with his subjects, that the Saxon tongue made so decided a start as it did during the ninth century. This illustrious monarch, who both by his enlightenment and his many virtues has rendered his time one of the most brilliant in English history, used all his personal leisure and all his personal influence to render into his native tongue the works written in the language of Rome. He was not a dab at Latin, and he knew it, which may possibly account for the loose style of some of his versions, containing, as they do, stray stories, fine bits of description, and even a devout prayer of an occasion, all commingled, in the most distracting manner

to a modern classic, with the text of his author.

2. The Conquest brought with it a change of langauge and a change of manners in the court; but it could hardly modify the speech of the stubborn Eng-lishmen of those days. In no long time the lordly Norman nobles found it to be their interest to study the despised tongue of the people they had conquered; and it is owing much more to the influence of Chaucer and Gower, and to the literary class gene-

# English Literature

and the extension of the monastic system, gave leisure for scholarship and induced thought. The close poli-tical intercourse that there was then with France improved both England and France in learning and in social manners. Such names as Lanfranc and Auselm, as Hales and Duns Scotus, as Michael Scot and Roger Bacon, show how entirely men were devoted, as they Bacon, show how entirely men were devoted, as they usually are in the infancy of a literature, where external peace and leisure will permit of it, to philosophy in both its branches of physical and metaphysical. The historical writers of the time, among whom we must mention William of Malmesbury, Geoffrey of Moumouth, Giraldus Cambrensis, and Matthew Paris, afferd a regressible offset to these subtle resource of the second states. afford an agreeable offset to those subtle speculators. Of course the learned language of the time was altoor course the rearrica language of the time was ano-gether Latin; and it is worth noting that the wit and fancy of the ecclesiastics could find as hearty expres-sion in the fine old drinking song of Walter Manes, beginning. "Mihi est propositum in taberus mori," or as Leigh Hunt elegantly renders it-" I devise to end my days in a taven drinking"—in the twelfth century, as they came to do in the sixteenth century, when Bishop Still improved the immortal bucchanalian song of "Jolly good ale and old." Personal satire and invective were much rifer in Mapes's day, than they became; and the weak king John and the charter of Runnymede afforded those disposed to employ those local squibs only too good targets to aim at. The "Gesta Romanorum," a singular medley of tales, apologues, and so forth, told often with much humour and pathos, have an interest of their own; and they possess, likewise, a horrowed grace. They have been instrumental in suggesting some of the noblest themes in our recent literature, and thus have double clams on our affection. The "Merchant of Venice" and "Marour affection. The "Merchant of Venice" and "Marmion," to go no farther from home, owe much to those old "Greats." These compositions resembled closely in their structure the French "Fabliaux." and have had a much greater influence on our literature. The fine old romances of "Havelok the Dane," the "Gest of King Horn," "Bevis of Hamptoun," "Guy of Warwick," and last and best of all, those glorious old legends written mostly in French, but composed by Englishmen, to celebrate the greatness and the downfall of the mythical king Arthur and his Knights of the Round Table, no English student of this literature will pass by. It was only the other day that we had an admirable poem from Alfred Tempson on the fragmentary materials of this very period. Meanwhile, an aumirable poem from Afred Tennyson on the frag-mentary materials of this very period. Meanwhile, the vernacular tongue of England, driven from the monasteries and the universities, was almost sclely de-pendent for its patronage and subsistence on the com-mon people of the land. It had no literature worth mentioning at this period; and it was rapidly merging into the Semi-Eaxon, as it is called, of which the carliest and best representative is the "Brut" of Lay-ton. The fundantly and fifteenth agentics branch The fourteenth and fifteenth centuries brought in, in truth, a new era into English history and Eng-John Wyeliffe and Geoffrey Chaucer were fought, and John Wyeliffe and Geoffrey Chaucer were born. The former deserves our ceaseless regard for his translation of the sacred Scriptures, the first ever effected by one hand (1380), and except Sir John Maundeville's one mand (1389), and except Sir John Maundeville's travels (1386), it is the first specimen of early English prose writing in our language. The latter deserves our undying esteem for his immortal "Canterbury Tales" (1390—1400), which, for their fine sportiveness and healthy pathos, their humorous simplicity and genuine tenderness, will be admired while the language ordures. It is to be remarked that the "Bruce" of Rarbour a Scutchusen an enin narrative written Barbour, a Scotchman, an epic narrative, written about 1376, is in purer English than those poems of about 137%, is in purer English than those poems of Chaucer of which we have just spoken. It resembles closely in its diction the English poem of "Piers Plowman." We can hardly do more than name a great many authors who crowd the canvas of the fifteenth and sixteenth centuries. Such are John Lydgate, whose "London Lackponny" (about 1430) is still read with interest; Alexander Burclay, author of the "Ship of Fools" (1500). Laby Skelton nuthor of the sation Chancer and Gower, and to the literary class generally, that French came materially to modify the existing language of England. These men knew French, because it was the tongue in which many interesting of books were written; and they gave it to the people of Fools' (1609); John Skelton, author of the satire books were written; and they gave it to the people of Fools' (1609); John Skelton, author of the staire balled in the firm belief that an acquaintance with twould advance their taste and improve their manners. Classical and theological learning were now King's Bench under Henry VI.; William Caxton, who much prosecuted. The founding of the universities, holds the honourable place of being the first who introduced printing into Britain (1474), his first book composed with types being the "Game of Cless;" Fabian (1512); Hall, an English lawyer and chronicler (1547); And Tyndale, who was burnt for heresy in 1536. The Sootch poetry of the period almost matches in interest and importance that of the south part of the island. James I, king of Scotland, led the way with his "Queen's Quhair;" Wyntoun, the chronicler (1420); Blind Harry, the author of the once highly popular performance known as "Sir Wm. Wallace;" Robert Henryson (died 1508), and wrote a beautiful poem called "The Testament of Cresseid;" Gavin Douglas, whose best work, among a considerable num-Douglas, whose best work, among a considerable number, is, without doubt, his translation of Virgil's "Æneid" into Scottish verse; and last and greatest of the poets of his country until the time of Burns, stands William Dunbar (died about 1520), whose "Daunce of the Seven Deadly Sins" showed him to have possessed imagination and humour, pathos and tenderness, boldness and vigour, in a very remarkable

3. The period extending from the English Reformation to the present time eclipses in brilliancy and gran-dour all the other eras of English literature. As the same sequence of events reigns in letters as in social life, the character of one era always determines the nature and complexion of the succeeding one. This is very observable in the Elizabethan age, on which we are now entering. The discovery of printing, and the discovery that all was not gospol that came from Rome, asservery that all was not gospol that came from Rome, were two as potent instruments as could possibly be put into the hands of literary men. What Skelton and Dunbar had begun, Spenser and Shakapere carried to a splendid consumulation. Doubtless an age so rife in new thoughts, and new images, and new forms of expression, could not have been heralded without its meed to blockled. The representations of Caracara of the could be a superior of Caracara of the statement of Caracara of of bloodshed. The names of Latimer, of Cranmer, of Ridley, and of Sir Thomas More, lie like dark shadows along the landscape of the literature of the time, men whose blood was shed by the rude laws that temporarily assumed the form of justice. The "Utopia" porarily assumed the form of justice. The "Utopia" of the latter is a work so proverbially imaginative that it has given the language a new word; yet so truly philosophical, and so full of elegant writing, as to be the wonder of the time at which it was produced. Roger Ascham, the learned tutor of Lady Jane Grey, and the writer of an excellent work, the "Schoolnaster," is another admirable miscellaneous writer of naster," is another additable miscellaneous writer of the time. As the English drama has already been taken up (see Drama), we need only mention here Sackville, who wrote the "Mirrour for Magistrates," and Brooke, author of the "Tragical History of Romeus and Juliet;" and the Scotsmen, Sir David Lyndsay, Roece, Major, McVille, and George Buchanan. "Lyndsay of the Mount," as he is sometimes called and George Rushumer, sell for a very defense, in chanan. "Lyndsay of the Mount," as he is sometimes called, and George Buchanan, call for a word of special mention, even in a summary like the present. The former was the companion of King James V. during his youth, and his unbeeded counsellor in old age. He wrote a huge kind of drama of the moral-play or interlude type, called the "Satire of the Three Estates" (1535), the irony of which is ordinarily aimed at the abuses of the clurch, but of which the humour is freshuses of the clurch, but of which the humour is freshuses of the clurch, but of which the humour is freshuses. abuses of the church, but of which the humour is frequently so gross as to render it unfit, at least, for general use. George Buchanan is universally admitted to have been one of the finest classical scholars who has appeared since the uge of Augustus. He mingled

complishments, but of vast compass and reach of undercompusaments, but or vast compass and reagent anatomatanding, and of minds truly creative; not men who perfected art by the delicacy of their taste, or digested knowledge by the justness of their reasonings, but men who made vast and substantial additions to the men who made vast and substantial additions to the materials upon which taste and reason must hereafter be employed, and who enlarged, to an incredible and unparalleled extent, both the stores and the resources of the human faculties." Not only was Shakspere taller by a head than any of his contemporaries, the men who proudly closed around him bulk larger, even to the critical eye, than any other collection of names in the entire roll of our literature. Even the minor dramatists of the time, such as Marlows and Chapman, Beaumont and Fletcher, Jonson and Drummond, are al-Beaumont and Fletcher, Jonson and Drummond, are almost the equals of any poets who have succeeded them. About the close of this period a number of sweet poets arose, who mostly wrote in a lyrical measure, though arose, who mostly wrote in a lyrical measure, though some of them were didactic; such as Fletcher and Browne, Drayton and Wither, Quarles and "holy George Herbert." During the period of the Restoration and the Revolution, the literature of the stage was exceedingly profligate. The court and the king had imported from France a love of genteel profligacy, which found its most fitting expression in the comedy of intrigue; and Wycherly and Congreve, Vanbrogh and Farquhar, are the dramatic scapegoass of the time. Yet the age was not wholly corrupt, for it could boast of such distinguished theologisms as Baxter, Owen, of such distinguished theologians as Baxter, Owen, Calamy, Collier, Leighton, South, Tillotson, and Barrow. This was also the time when Milton, who stands row. This was also the time when Milton, who stands in the front rank of poets, lived and sung of Paradise lost and of Paradise regained, writing "something," as he early hoped himself, "which posterity would not willingly let die." Marvel ridiculed the High Church, and Butler, of "Hudibras" fame, burlesqued Dissent; Walton angled, Looke speculated, Newton discovered, and John Pryden "found the English language of brick, and left it of marble." The literary history of the 18th century, and particularly of the reign of Queen Anne, has been censured severely by some, and praised to excess by others. It was patural that the praised to excess by others. It was natural that the critics of the period should be inclined to over-estimate the influence of the literature among which they lived; but many writers of the present day have decried it, possibly with a considerable touch of truth, for its polite scepticism and for its hollow insincerity. It has been glorified by its advocates as the Augustan age of English literature, and decried by its enemies as an age of utilitarianism and satire. The truth is, that both in poetry and in prose the form had come to be observed poetry and in prose the matter. Pope, of course, is the poetical chief of this age; and while he, no doubt, indulged much more than was meet in the most polished dulged much more than was meet in the most poissined and most personal satire, he nevertheless, as in his "Essay on Man," displays a fine power of lofty contemplation, and a faculty of expression so brilliant, so happy, and so copious, that we look in vain for the match of it in the entire range of English poetry. Addison is unmatched for grace and ease; Swift has no equal in rude, pointed vigour; and the sense of Johnson's ponderous sentences is frequently obscured by their size. If Young, Akenside, Thomson, Gray, Collins, Beattie, and Cowper were animated by a truer Collins, Beattre, and Cowper were animated by a truer sense of their duty in writing poetry than Pope was, the result shows that they accomplished much less than he did. This greatest poet of the century was Robert Burns. Its novelists were Richardson, Fielding, Smollett, Sterne, and Goldsmith; its historians ware Hume, Robertson, and Gibbon; and its philohas appeared since the age of Augustus. He mingled much in the politics of his time, yet found leisure to carse his genius in the retired ways of academic seelusion. The founding of the Scottish universities, and the institution of grammar and parish schools, which owed their origin entirely to the indefatigable labours of the reformer knox, bade fair to give to Scotland in important place in the history of Great Birtian. We now come close to the greatest era in the history of English literature. In all the essentials of true genius this age can give way neither to the best days of ancient Greece or Rome, of modern Italy or France, the greatest men the nation has ever produced come treoping up at the mention of Queen Elizabeth's name. There is Shakspere and Sponser and Sidney; there is Malkspere and Sponser and Sidney; there is Malkspere and Sponser and Sidney; there is Milton and Hobbes and Cudworth, and many other has been none so various, so diverse, and readers have increased almost as abundantly as the books have. This is the age of roviews and periodicals, and, indeed, of novels and romanoes. The greater struct results are than he didd. The greatest prect of the century was that tuey accomplished much as the hold diddid that greatest prect of the cid. The greatest prect prect of the cid. The greatest prect precise and Gobern, and Gibbon; ing. Smollett, Sterne, and Gibbon; ing. Smollett, Sterne, and Goberns, and Gibbon; ing. Books have been multiplied to an unprecedented degree, and readers have increased almost as abundantly as the books have. This ing, Smollett, Sterne, and Goldsmith; its instorians were Hume, Robertson, and Gibbon; and its philosophers were Butler, Berkeley, Clarke, Shaftesbury, Hume, Paley, and Adam Smith. The first half of the 19th century opens with a galaxy of poets more brilliant, probably, than any that have appeared during an equal number of years in the whole history of English literature. Coleridge, Wordsworth, Scott, Byron, Shelley, Keats, Campbell, and Southey, are the poets of this time. There might be periods of greater originality but there has been pour so various, so diverse, Smith, Habitt, John Fester, De Quincey, and Carlyle; the great preachers are Hall, Chalmers, and Irving; the philosophers are Stewart, Mackintosh, Bentham, Brown, Hamilton, and Stuart Mill; the men of science are Owen, Whewell, Faraday, Sedgwick, and Huxley; the novelists are Dickens, Thackersy, Bulwer Lytton, Charlotte Bronté, and "George Eliot;" the historians are Hallam, Macsulay, Thirlwall, Grote, Milman, and Carlyle. Ruskin stands alone as a writer on art. In poetry we have Tennyson, the Brownings. Matthew and Carlyle. Ruskin stands alone as a writer on art. In poetry we have Tennyson, the Brownings, Matthew Arnold, Smith, and Massey, besides a host of other. America has been active in sustaining her credit as a scion of Saxon stock, and can number among her writers W. Irving, Poe, Longfellow, Cooper, Prescott, Emerson, Bancroft, Hawthorne, and Lowell, who have given us excellent prose and very good verse.

ENGRALIND, en-gratid (Fr. engréler, to indent in curred lines, to variegate), the name given to a particular form of partition line used in Her. It consists of a series of semicircular or scalloped indentations, the points of the indentations being turned outwards, or

points of the indentations being turned outwards, or projecting into the field when the line is used, as it is principally, for defining the outline of any simple ordinary or sub-ordinary.

ENGRAVING, en-grai'-ving (from Fr. graver, to en-grave), the name given to the art by which plates of metal or blocks of wood are prepared by incision or excision in order to imprint designs of any kind on paper, calico, or similar materials. The term engra-ving is more strictly confined to work of this nature executed on wood or metal; but there are also many different branches of the art, to which specific names are applied: thus, the process of engraving dies in steel for coins and medals is called "die-sinking" (see Steel for coins and medians is called "die-sinking (see Dir-sinking), while engraving on precious stones and shells, which consist of layers of different colours, so that, by cutting away a portion of the upper coat, a dark figure may be produced on a light ground, or time versa, is termed "cameo-cutting." (See Cambo.) This branch of the art is somewhat similar to chasing, by which figures and patterns are produced in bas-relief on vessels of gold or silver. There is a great difference in the method used in preparing blocks of wood and plates of metal to effect impressions on paper. In the former, all the parts that are to appear white in the impression are cut away, and the lines which produce the imprint are left on the face of the block (see WOOD-ENGRAVING); but, on the contrary, in engraving on steel, copper, or zinc, the lines which are intended to produce the impression are hollowed out with a graving-tool. The Egyptians practised the art of engraving in bas-relief and intaglio on stone and metal at a very early age, and the Jews and Greeks probably derived their knowledge of the art from them. Indeed all the nations of the East have practized engraving of screens kinds from a very have practised engraving of various kinds from a very early period of their history, although none of them ever discovered the practicability of taking impressions ever discovered the practicability of taking impressions from incised plates, or wooden figures in relief. It was about 500 n.c. that a Greek named Aristagoras is said to have produced a map of all the portions of the world that were known to the ancients at that period, graven on a plate of brass. The incised lines were probably filled in with a coloured composition, so that the whole presented an appearance somewhat similar to the nicllo-work of the middle ages, or the accord kind of the early encapatic paintings. (See second kind of the early encaustic paintings. (See ENCAUSTIC PAINTING, NIELLO.) The method of pro-ducing incised engravings on plates of metal for the purpose of ornamentation, was followed without the slightest variation in the manner of execution from the earliest times until the discovery of the art of printing, and the mode of taking impressions from engraved plates. The art of obtaining an imprint from wooden blocks and types is ascribed to Laurence Koster, wooden blocks and types is ascribed to Laurence Koster, of Haarlem, who printed a book of rude wood engravings on Scripture subjects, with texts of Scripture at the foot of each print, entitled Speculum Humana Salvationis, about the year 1439; but the merit of the earliest discovery of printing from metal plates is assigned to Masso Finneguerre, of Florence, who took an impression on paper from a large silver plate known as the "Pax," which he was engraving in mello, about twelve years after the discovery of Koster, who was then printing from movable types out in metal. After

this, the progress made by the Germans and Italians in engraving on wood and metal was rapid, and before the close of the 15th century, books ware produced copiously illustrated with maps and engravings im-printed from metal plates. Prior to the time of Albert printed from metal plates. From the time of alores, burner, engraving had been effected by means of the graving-tool alone; but this great artist introduced the method of engraving known as etching, by which the design is bitten in, as it is technically called, by the corrosive action of a strong acid on the surface of the corrosive action of a strong acid on the surface of the plate, after the design has been traced with a needle on the etching-ground, with which the plate has been previously covered. It should, however, be stated that the discovery of the art of etching by means of acid is ascribed by some to Parmegiano, who lived at the same time as Albert Durer. The style of engraving called "mezzotinto" was introduced by De Siegen about 1840: considerable improvements were with convention of the art because the strength of the art because of the art because the strength of the art because of the art by the strong the strong the strong the art because of the art bea subsequently effected in this branch of the art by subsequently effected in this branch of the art by Prince Rupert. Copper was the material used for all engravings, whether of maps or landscapes, in line, aquatinta, stipple, or on soft ground, until about the year 1815, when soft steel plates were first used by Mesers. Perkins and Heath, of Philadelphia, instead of copper, which were afterwards hardened when the process of engraving had been effected. The tools used in engraving are greater as the line of the control of the contro process of engraving had been effected. The tools used in engraving are gravers or burins of all kinds and forms, made of case-hardened steel, etching-needles, scrapers for removing the burr thrown up by the graver or dry point, and burnishers to remove scratches from the plate, and to give a tone and finish to the engraving. The plate is prepared for the reception of the design by covering it with a coating of etching-ground, composed of a mixture of wax, resin, and gum-mastic. This is smeared over the plate after the scheme heated ears being taken to render the it has been heated, care being taken to render the surface of the ground uniform. It is then blackened by holding it over the smoke of a candle; and as soon as this is done the plate is allowed to cool. The outas this is done the plate is allowed to cool. The outline of the drawing or map to be engraved, which has
been carefully traced in pencil on paper, is next transferred to the ground by pressure, or by rubbing it with
a burnisher, and the design thus obtained is traced
through the ground with a needle. A rim is then
raised round the edge of the plate with what is called
"banking wax," and a solution of nitric acid and
water is poured into the hollow thus formed. When
this has remained on the plate a sufficient time to bite this has remained on the plate a sufficient time to bite in the outline, or the lighter parts of the engraving if it be a landscape or figures, the acid is poured off, and the parts which are dark enough are covered with a kind of varish called "stopping-ground," which resists the corresion of the acid, and prevents it from acting on the plate in the parts thus covered. The plate is then again subjected to the action of the acid, and the resistance of the plate is then again subjected to the action of the acid, and the process of explains the atomyte, ground to and the process of applying the stopping-ground to those parts which are sufficiently dark and the acid to those which are not dark enough, is continued until all the requisite gradations of light and shadow have been the requisite gradations of light and shadow have been obtained. The plate is afterwards fluished with the graver. In line engravings, the greater part of the work is done by the burin, a skilful engraver being able to produce a vivid representation of the surface of any object or material by a judicious combination of lines and dots. Among the best engravings of recent date may be mentioned that of Sir Edwin Landseer's beautiful picture of Titania, by Samuel Convince. Cousins.

ENGEOSSING, en-grose'-ing (Ang.-Nor.), among lawyers, means the making of a fair copy of a deed upon stamped paper or parchment, in clear legible characters.

Engrossing, in Law. (See Fourstalling.) Enhanmonic, an Law. (See Forstalling).
Enhanmonic, enhan-mon'-it, a term employed by
the ancient Greeks to designate that of their three
genera or scales which consisted of quarter-tones and
major thirds. Besides this they had originally another
kind of enharmonic much simpler and easier in crecution, and upon which the theorists of the old school
considered the great teams. considered the quarter-tones or diesis as innovations too refined and artificial. There is also a species of enharmonic called equi-rocal or enharmonic change, in which the notation is altered, but the same keys of the instrument are used.

ENIGMA, e-nig'-mā (Gr. ainigma), a description or

definition of a thing given in obscure or ambiguous terms, with the object either of hiding what the thing is, or of occasioning its discovery to come as a surprise. In ancient times enigmas were considered of such worth that envoys were sent between the Eastern monarchs solely for the purpose of solving them. They were often used as the vehicles for conveying truths of the greatest importance. As familiar instances of the enigma among the ancients, may be mentioned that which Sameon propounded to the Philistines, and also that of the Sphinx, which was solved by Œdipus. As a matter of literary display, the enigma has been a favourite at many times and among many nations. In France, during the 17th century, it was much in vogue; in fact, several ponderous treatises were written concerning its nature and history. Some of the greatest poets in Germany did not disdain to write enigmas, and several of Schiller's are incorporated in his published works. One of the most beautiful compositions of this kind is the enigma, generally attributed to Lord Byron, on the letter H, beginning. "Twas whispered in heaven, and muttered in hell." In the present day the enigma is looked upon only as a species of pleasant amusement by which the time may be beguiled.

Ennisyment, en-list\*-ment (Ang.-Nor.), in Mil., the name given to the act by which any one agrees to perform certain duties that are required of him as a sol-

form certain duties that are required of him as a soldier, during a certain period of time, for a fixed amount of remuneration in the form of daily pay and bounty money, which he receives when he joins the service. Enlistment is a voluntary act, and differs entirely from the compulsory system of drafting men for military service adopted generally in France and throughout Europe, and termed conscription. The only case in which military service is made compulsory in this country is that of balloting for the militia when any regiment; is deficient in numbers; but this is never any regiment is deficient in numbers; but this is never resorted to except in times of extreme urgency, and even then exemption can always be purchased by pro-viding a substitute. The period of enlistment in the British and Indian army is now fixed at ten years for the infantry and twelve for the cavalry, engineers, ar-tillery, and marines, to commence from the day on which the recruit takes the outh of allegiance, if he which the recent takes the outs of allegiance, if he have already attained the age of eighteen, or from his eighteenth birthday, if this happen after the time when he was sworn in. In the navy a man may enter for continuous service for five or ten years; but he is liable to be detained in her Majesty's service for six months more if it be found necessary to do so, or even for an additional period of five years by royal procla-mation, in event of his services being required through mation, in event of his services being required through any serious emergency. When the recruit has en-listed and received the customary shilling, he has twenty-four hours given him to consider the step he has taken, Sundays, Christmas-day, and Good Friday, being dies non in all cases. After this time has ex-pired, the sergeant is bound to serve him with a notice of his enlistment, and after the lapse of another entire day he must appear before a magistrate, who reads and explains to him the parts of the Articles of War that relate to mutiny and desertion, and administers the oath of allegiance. If, however, he does not still desire to become a soldier when he appears before the magistrate he is at liberty to draw heigh on returning magistrate, he is at liberty to draw back on returning any money he has received from the sergeant as enlistment money or pay, with twenty shillings in addition as a fine for his withdrawal from his engagement, which is termed "smart money." Apprentices may not enlist without the consent of their masters. may not enlist without the consent of their masters, who may claim them from the military authorities within a month from the period of enlistment. Apprentices enlisting and concealing the claim that their masters have on their services, are considered as having obtained money under false pretences, and may be prosecuted and punished accordingly. They are also liable to serve as soon as they are out of their apprenticeship, and may be apprehended as deserters if they do not surrender themselves to a recruiting officer.

EMOCH, BOOK OF, 6'-nok, is one of the apocryphal books of the Old Testament, and believed by some to be cited by St. Jude when he says, "Enoch, the seventh from Adam, prophesied, saying," &c. It is

generally supposed, however to have been fritten after the establishment of Christianity, from the frequent allusions that are made in it to passages of the New Testament; and it is probable that the author took occasion, from the words of St. Jude, to perpetrate the forgery. As for St. Jude himself, it is probable that he cites, not from any book of Enoch then subsisting, but from general tradition. The book was common in the early church, but was not generally received as canonical, and appears to have been lost about the 8th century. Bruce, however, when in Abyssina, was fortunate enough to obtain three complete MSS. copies of this work. An English translation was published in 1828, by Archbishop Lawrence, and the Ethiopic version in 1838. Several German editions have appeared. The book is chiefly taken up with a relation of the prophetic visions of Enoch regarding the fall, heaven, hell, nature, astronomy, the future of the Jewish people, &c.; the whole being characterized by such absurdities as

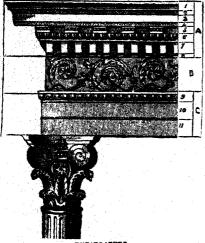

the whole being characterized by such absurdates as to render it unworthy of any credit.

ENSIGN, ent-eine (Fr. enseigne; Lat. signum, a standard), in Mil., the name given to commissioned officers of the lowest rank in the line. The ensign ranks immediately after the lieutenant. It is the duty of the senior and junior ensign in every regiment of infantry to carry the colours,—the former carrying the queen's colour, or union-jack, and the latter the regimental colour, which is generally of the same tint as the facings of the regiment, and has a small union-jack in the corner and the number of the regiment in the centre, with the names of the battles in which it has been engaged emblazoned round it on embroidered scrolls. In the foot-guards ensigns rank as lieutenants, and in the engineers, artillery, and marines, the duties are performed by a lieutenant, who receives less pay than the senior lieutenant of the company, and was formerly atyled second lieutenant. The ensign originally derived his title from the duty that devolved on him of carrying the standard, which was formerly amark or rallying-point for the soldary in battle. In the present day it is a point of honour for a regiment to preserve its colours, and the ensigns who carry them are closely attended by a guard of sergeants, who wear a flag curbroidered on the arm above their stripes, and

are called colour-sergeants.

EXTABLATURE, en-tib'-listure (Fr. entablement, Sp. entablement), in Arch., the whole of the superstructure that is supported by two or more columns which esustain the roofing of a portice or entrance to any building of importance built in the classic style of architecture. The entablature sometimes supports a pediment with sides sloping downwards from the contreto either end. It is divided into three parts,—the srchitrave, the frieze, and the contice. (See Architerave, Frieze, Cornice.) The depth of the entablature and its component parts is determined by the diameter of the lower end of the shaft of the column. (See Architecture). The entablature in each of the very orders of architecture is distinguished by certain methods of treatment and decoration. The Tuscan entablature consists of a plain architrave and frieze separated by a narrow projecting fillet, and surmounted by a cornice formed of simple mouldings, as fillet, and cymatium. In the Doric entablature, guitae, or rain-drops, are attached to the under-side of the fillet or tentia that separates the architrave from the frieze, immediately under the triglyphs that ornament he latter; mutules are also placed on the cornice above the triglyphs. In the remaining orders the architrave is broken into two or more fillets, or facias, projecting one above another, with an ornamental immediately under the fillet above it. The frieze is generally plain in the Ionic order, as in the Doric, although it is sometimes enriched, as were also the sustopes, or rectangular spaces between the triglyphs on the frieze of the last-named order; but in the Corinthian and Composite orders it was richly adorned with sculpture in bas-relief. The cornice in the Ionic, Corinthian, and Composite orders it was richly adorned with sculpture in bas-relief. The cornice in the Ionic, Corinthian, and Composite orders it supported on a moulding curiohed with dentils, and finished above with an ogee moulding; but in the Corinthian order the cornice is supported o

tioned; while in the Composite order mutules are substituted for the carvet modifilions. In the accompanying engraving of an entablature of this order, the three principal component parts—the cornice (A), the frieze (B), and the architrave (C)—are clearly and distinctly separated by marginal lines, extending to the right and left, which indicate the exact space occupied by each. The cornice admits of a great number of sub-divisions. At the very top is the symstimm (1), formed by the moulding known as the syms rects, and resting on an enriched egge of bed-mould (2). Below this is

ENTABLATURE.

a fillet termed the corona (3), resting on a similar beda fillet termed the corona (3), resing on a similar bet-mould (3), which is supported in its turn by a mutule band (5), consisting of a fillet adorned with mutules at regular intervals. Between the mutule band and the fillet enriched with dentils (7), or the dentil-band, astit is frequently termed, is an echinus moulding (6), and below the dentil band another narrow moulding (8), below the dentil band another narrow moutaing (o), which serves as a bed-mould for the entire cornice. waten serves as a nea-mount for an entire contest. The middle portion of the entablature,—the frieze, consists of a broad fillet only, enriched with a scroll-work of leaves and flowers. The architrave is divided into three parts,—an echinus moulding, distinguished as the architrave moulding (9), and two fillets separated by a parrow head-moulding, and termed the facia (10) and lower facia (11) respectively.

ENTAUL, en-tail, in Law, is a term commonly applied to the form of an estate, technically in England and Ireland called a fee tail, and in Scotland a tailrie. It is said to be derived from the French tailler, 'to cut, oither because the heirs general are by this means cut off, or because this estate is a part cut out of the whole. An estate in fee tail is a limited fee, as opposed to a fee simple; it is that which a man hath to hold to him and the heirs of his body, or to him and particular heirs of his body, according to the will of the donor. Previous to the passing of the statute de Donis, 1285, lands, if to the passing of the statute de Donis, 1285, lands, if to lessen the injurious effects of this system, and which given to a man and the heirs of his body, were regarded as conditional estates in fee simple; but the nobility, being surious to perpetuate their possessions in their own families, procured the passing of that statute. It emacks, that from thenceforth the will of the donor is read to be observed, according to the form in the deed of gift, and that the tenements so given (to a man and the heirs of his body, or the heirs male of his body, or the heirs of his body, or the heirs male of his body, or the heirs of his body, or the large, where the denor or his heirs. Estates failed, should revert to the denor or his heirs. Estates failed, should revert to the denor or his heirs. Estates failed, should revert to the denor or his heirs of the ten; the larger, where the gift is to the heirs of the some of the heirs of his body by a particular pore us; as by his now wife. In the former case, his issue in general, by all

and every marriage, is, in successive order, capable of inheriting the estate tail; in the latter, no issue can inherit but that of the two designed. Each of these may be again either in tail male or tail female. "The establishment of this law," says Blackstone, "occasioned infinite difficulties and disputes. Children grew disobedient when they knew they could not be set aside; farmers were onsted of their leases made by tenants in tail; for if such leases had been valid, then, under colour of long leases, the issue might have been tenants in tail; for if such leases had been valid, then, under colour of long leases, the issue might have been virtually disinherited; creditors were defrauded of their debts; for if tenant in tail sould have charged his estate with their payment, he might also have defeated his issue by mortgaging it for as much as it was worth. Innumerable latent entails were produced to deprive purchasers of the lands they had fairly bought,—of suits in consequence of which our ancientbooks are full; and treasons were encoursed, as estates tail were not liable to forfeiture longer than for the tenant's life." But the nobility were always fond of this enactlife." But the nobility were always fond of this enactment, because it preserved their family estates from necue, occause it preserved their family estates from forfeiture. At length, however, in the twelfth year of the reign of Edward IV., it was decided, in the celebrated Taitarum's case, that by means of certain fictitious proceedings, known by the name of a common recovery, suffered by the tenant in tail, he should convert his estate into a fee simple should. recovery, sunered by the tenant in tail, he should con-tert his estate into a fee simple absolute, and her all persons whatever claiming the estate tail, or any estate ulterior thereto; and by long use and acquiescence these recoveries became the legal mode of conveyance by which a tenant in tail might dispose of his lands and tenements. Afterwards, in the reign of Henry VIII., estates tail were declared to be forfeited on any conviction for high treason; and soon after, in the same reign, certain leases made by tenants in tail, which do not tend to the prejudice of the issue, were allowed to be good in law, and to bind the issue in tail. The peculiar privileges of tail estates were still further curtailed by subsequent statutes, but most of all by 3 & 4 Will. IV. a. 74, enabling a tenant in tail, by an ordinary deed of conveyance, duly enrolled, without any indirect or fictitions proceeding, to aliene in fee simple absolute, or for any less estate, the lands custailed. Subsequently, by 1 & 2 Vict. c. 110, entailed estates were rendered liable for ordinary debts; and further, by 19 & 20 Vict. c. 120, a tenant in tail may demise the same from time to time for any term not exceeding twenty-one years. Estates tail have those or gradually unfettered, and are now subject to not tend to the prejudice of the issue, were allowed to been gradually unfettered, and are now subject to even less restraint than is attached to conditional fees even less restraint tran is attached to bound an ear at common law, after the condition was performed by the birth of issue. In Scotland, the history of the entail system differs from that of England, in so far as it was there built and strengthened by the ingenuity of the lawyers, who, as fast as assailable points were dis-covered in the form of the deed, fortified it with new covered in the form of the deed, fortilled it with new classes. Thus, what are known as the "prohibitory," "irritant," "resolutive" clauses, were introduced; and by a statute of the Scottish parliament in 1685, entails in that country were reduced to a systematic form. The injurious effects of this enactment were widely felt in Scotland during the 18th and nearly the half of the 18th centuries; but it came to be the practice in law to insist upon the very strictest interpretation of the deed; and any error in the form, or even a clerical to insist upon the very strictest interpretation of the deed; and any error in the form, or even a clerical error, as the omission of a word, would vitiate the entail. At length, Andrew Rutherfurd, the then lord advocate, introduced a measure into parliament to lessen the injurious effects of this system, and which was embodied in 11 & 12 Vict. c. 36. By means of this act, which came into force on the let of August, 1800 persons than in existence and helding under

Entomology

in the outset may be high and the pulse strong and hard, it soon becomes small and weak or wiry. The names and vomiting are often most distressing, its of retching often constnuing after the stomach has been deprived of its contents. In bad cases, as the disease proceeds, the abdomen begins to swell and becomes tense and symmentic; hierary sometimes comes on; the pulse intermits, or bests irregularly; the extremities grow cold; the features are sharpened and ghatly; cold sweats break out; the pain, perhaps, ceases, and death at length acts; in. The brain is generally unsflected, and the intellect remains clear; but sometimes delirium occurs late in the disease. Entertits may arise from warious causes, particularly from cold times defining occurs late in the disease. Entering may arise from wirrious causes, particularly from cold and wet, more especially applied to the feet or legs, or cold drinks when the body has been previously overheased. Hardened fareal matters, arising from indigestible substances taken into the stomach, may also produce this disease. Strangulated hernia, or the involution of one fold of the intestine within aucher, may induce this disease, by causing a complete obstruc-tion to the passage of the contents of the bowels. Various diseases bear a considerable resemblance to enteritis; but that which most closely resembles it is colic, which, indeed, often passes into enteritis. Colic, which, indeed, often passes into enteritis. Colic, however, is distinguished from enteritis by the absence of fever, the difference in the state of the pulse, the pain occurring more in paroxyems, and by being usually mi-tigated by pressure; whereas, in enteritis, it is in-creased. The ordinary remedies employed in inliammation must be resorted to in this disease. Blood is to be freely taken from the arm, leeches are to be applied to the abdomen, and afterwards fomentation-cloths. Great care is necessary in the administration of purgative medicines, as they frequently tend to agor purpasses measures, as they frequently tend to ag-gravate the symptoms, and ought not to be resorted to till after the liceding. The disease is to be cured by removing the inflammation, not by opening the bowels. The judicious administration of opium and bowels. The judicious administration of opium and calomel is often of the greatest benefit in this disease; and the best laxative to give, in order to clear out the bowels, is easter oil. Though there may not be much danger in mistaking colic for cuteritis, the greatest danger may arise from mistaking enteritis for colic. Stimulants, cordials, or carninatives, which are often of the greatest service in colic, would greatly aggravate the symptoms in enteritis. vate the symptoms in enteritis.

Take the symptoms in enterius.

ENTHUSIASM, en-thu'-ze-azm (Gr. enthousiaemos, inspiration), is an exalted condition of mind, in which
the imagination is inflamed and exalted, thereby conceiving and expressing extraordinary and surprising things. The excesses of the imagination are of two kinds; viz. I. When, within its proper sphere, it gains so great a power that all the other affections and motives of human nature are overborne and excluded; and 2. when the imagination trespasses upon ground where it should have little or no influence, and where it can only prevent or disturb the operation of reason and right feeling. In the latter case the solvicties of good sense and experience, the motives of interest, and even the dictates of rectitude, may be set at marght, and the commonest objects may be invested either with preposterous charms or with unreal deformities. which preposerous charms of with unreal deformaties. There are, however, perhaps few minds that are not to some degree subject to constitutional fictions, which to a greater or less extent intercept the view of things as they really are. Naturally the pleasurable emotions which scoompany the exercise of any of the active powers, and which serve to stimulate to exertion, are always subordinate and subservient, never predominant or importante. In minds of an unbealthy temperament the emotion of pleasure, and the consequent excitement, may be disproportionate to the strength of the faculties; there may be more of commotion than of action, more of movement than of progress, more of enterprise than of achievement; the efficient power of the understanding is thus overborne and left in the the understanding is thus overborne and left in the rear. "Where there is no error of imagination, no misjudging of realities, no calculations which reason condemns, there is no enthusiasm, even though the sould may be on fire with the velocity of its movements in pursuit of its chosen object." "To apply an epithet which carries with it an idea of folly, of weakness, and of extravagence, to a vigorous mind efficiently, as well as ardently, engaged in the pursuit of any substantial and

important object, is not merely to misuse's word, but to introduce contation among our notions, and to put to introduce contation among our notions, and to put to introduce to suit is deserving of respect."—Ref. Matural History of Enthusiasm, by Isane Taylor.

ENTRYMENE, en'the meen (by enthuseme, from en, and thuses, the mind), is a term employed in Riet, introduced by Ariatotie, and which since his time till recently has been almost universally misusderatood. It has generally been defined to be an imperfect ayllogism, having one or other of its premises not appressed, but understood. Though several writers before his time had pointed out the error of this definition. Sir W. Hamilton was the first to call general attention to it, in an article in the Editating Review for April, 1633. This error, he says, "has been believed; believed without any ongent evidence; believed from the most ancient times; and even when the opinion was at last competently refuted, the refutation was itself so completely loggotten, that we do not believe there is at present a logical suthor, not to say in England, but in Europe, who is even aware of the existence of the controversy." De Quincey states, in his essay on Rhetorio, that many years ago, when studying the Aristotelian rhetoric at Orford, he was convined that, by whatever name Aristotle might describe the main purpose of rhetoric, practically, at least, he threw the whole stress upon finding such arguments for any given thesis as, without positively proving of disapproving it, gave it ac colourable support; but how to main purpose of rhetoric, practically, at least, he threw the whole stress upon finding such arguments for any given thesis as, without positively proving or disapproving it, gave it a colourable support; but how to reconcile this with Aristotle's formal account of the office of rhetoric, that it consisted in flading, enthymemes, he could not perceive, till his friend Sir W. Hamilton communicated to him an essay of Faccionatis's (1724), entitled "De Enthymemesta." An enthymeme, then, differs from a syllogiam, not in the accident of suppressing one of its propositions,—either may do this, or neither; the difference is essential, and in the nature of the matter; that of the syllogism being certain and apodeictic, that of the esthymeme probable, and drawn from the province of opinion.

Enromology, ento-mol'-o-je (Gr. enfones, an insect; logos, a discourse), that branch of science which treats of the habits, properties, and organization of insects. The name insect implies an animal insected or divided into segments. This term is applicable to the principal part of the articulate sub-lingdom, and was formerly applied to it; at present,

came to the principal part of the articulate sub-kingdom, and was formerly applied to it; at present the word insect is only used in reference to those articulated animals which are distinguished by anten-me and breathing organs composed of rainfied trachese, with or without air-sacs. The science of entomology presents to the student of nature the most numerous and diversified objects worthy of attention. The observation of the structure and instincts of insects is full of varion of the structure and instincts of insects is init of interest, and has at all times engaged the attention of men of science. Along with other branches of instoral history, the study of entomology was cultivated by Aristotle and other philosophers among the ancient Greeks. Pliny does not add much it his works to the Greeks. Pluy does not add much in his works to the information given by Aristotle, and it was not studied as an absolute science till the 17th century, when progress began to be made. The chief naturalists of that period were Goedart, Swammerdam, Malpighi, Lecuwenhoeck, and Ray. The science, however, was very backward, as Ray estimated the whole number of insect species in the world at 10,000. At the present insect species in the world at 10,000. At the present day, it has been secentained that a larger number than this exists in this country alone. During the 18th century, the great Swedish naturalist Linnaus gave his attention to the study of entomology, and his attention, as far as the orders are concerned, has served as the basis of all that have been since promulserved as the basis of all that have been since promulgated. It is founded on the presence or absence of the wings, their number, consistence, surface, position in repose, and also on the presence or absence of a sting. By this classification, macets were at first divided into seven classification, macets were at first divided into seven classification, adopted in the "Encyclopedia Britannics," is taken from an admirable article by James Wilson, of Woodwille. Bleven different orders of insects are enumerated: 1. Colcopters (Gr. kolcos, a sheath; pieron, a wing), including all those kinds commonly called besties. Their membranous wings, which are the true organs of flight, are protected by a superior and **Entorce** 

anterior per of havilly satisfactors, called slyres. They are all mathematics, and the state of the mathematics of the state of the mathematics of the state of the consistence of present and mathematic of the subject which the state of the consistence of the state of the consistence of the state of the mandatus of the mathematics as the inferior pair. The mandatus and maxilles are replaced by a sheath and suckers. A Neuropters of reservon, more percentage, a warmy, nathoding Bedules or dragon-flee, ephemeras, the Both pass of wings are membranous, naked, and flavorabled with mandables and maxilles—5 Hymenopters of the ware, a membrane; percent, and characterised likewise by membranes of and other suckers of the wise, a neuronal state of wings, and the suckers of the wise of when mandatus, and are not restoulated, as in the preceding order. The mouth is turnished with mandables and maxilles, and the abdomatic of the female is terminated either by an outpostor. ence, coiled elytra, exteriord with ment-plane (Gr. orthas, ling crickets, grade-r wines are of the anterior pair of handle , commit men of the female a terminated either by an ovipositor or a sting.—S Lepidopters (Gr lepis, a scale, pieron, a wing), containing all butterfiles and moths, and generally characterized by the farmaceous or scal, as-nect of the organs of flight, and the tubular or thread-like entension of the parts of the mouth —7 Strepsipters (Gr. strepsis, a turning or twisting, pieron, a wing), including a few peculiar and parasitical species belonging to the genera-Stylops and Zenos —8 Dipters (Gr. sts, twice; pieron, a wing), including the house-length, and other two winged kinds. The mouth is fermished with a proboscis, and there are two organs, called poisers or balancers (halteres), placed behind the true wings, one on each side —9 Suctoria (so designated from their sucking propensities), is constituted by the genus Pulex of Limmeus and difficis from the ensuing apterong orders in undergoing a regular men of the female is terminated either by an ovipositor the ensurary spectrum or himself and districts from the ensurary spectrum orders in undergoing a regular metamorphous, and possessing what some regard us the rediments of elytra.—10 Thysmoura (or the od., I dance; cura, a tail, hisewise an apterious order, including the Peduro and other tribes It evidently derives its name from the springing propersities of its order, which leap by means of a settloria process beat beneath the abdomen —11. Parasits (so named from their perfections of adheave propensities, because they dwell on the bodies of other animals) cont ins the genus Pediculus of Linneaus, and the Norm, or bird-lice (See the articles on the above orders for their parties lar characteristics )

lar characteristics )
Exposed, en-to-so'-d (Gr. entos, within, 2000, an animal), a term applied to those animals which live within others. They are of low organization, and generally expuniform in structure. In most cases the blood is equousless, and circulates, in the higher or gamed species, in a closed system of vessels. They have no inspiratory organs, no articulated members for locomotion, and no organs of sense. In the higher converged attacks. organized culozos, a filamentary nervous system has been recognized Several species of entozon infest the himsp body. (See INTESTIMAL WORLS)

He will be control of the control person who claimed title to the freehold was taken away, and he could not recover possession against the heir by this summary method, but was driven to his action to gain a legal seism of the cetate. A writ of entry was also a method [of gaining possession of disputed property by trying the title of the occupant, where he had not only a bare possession, which might be destroyed by entry, but also an apparent right of possession. This writ was directed to the sheriff, requiring him to command the tenant of the lead that he render to the demandant the land in question. The possession. This writ was directed to the sheriff, requiring him to command the tenant of the lead that he render to the demandant the land in question. The tenant was thereupon compelled to deliver up the possession of the land, or to show rause for not floing so, and thereupon the possession of the land was awarded to him that could show the clearest right to it. These forms however, were in effect abolished by 3 \$\frac{1}{2}\$ & Will IV c 27, which declares that no person shall be deemed to have been in possession of any land within the meaning of that act merely by reason of having made an entry thereon, and no continual or other claim upon or noar any laid shall preserve any right of making a tentry. The right of entry is now lost by not asserting it? I tently team.

INVELORE MARY OF entrope, on vel-ope (from Fr. sant lapper, to inverse)—Before the introduction of the penny 7 istage, a double charge was levisd on all letters which consisted of two pieces of paper. After the cheap postage was established, the restriction which caused the letters themselves to be sealed or wasfered, was removed. Nearly all letters are now inclosed in an envelope or covering; and as upwards of 500,000,000 of letters pass through the post-offices in this country alone, the manufacture of envelopes is one of no slight importance. The French made sinvences after the restriction and when

in this country alone, the manufacture of envelopes is one of no slight imports see. The French made suvelopes before they were used in England; and when first manufactured in this country, they were made by hand, an expert maker being able to fold three thousand in a day. The general use of envelopes dates from 1840, and several injentious attempts to make them by machinery date from this paried. In the earliest stages of the invention of suvelope-making machines, the paper blanks were cut out and the folding afterwards done by hand; but the pressing necessity of an increase in the power of production led to the extension of mechanical means to the suffice process. A first step towards this result was the suvention of an improved paper-cutting machine for esting out. portiginal atports of a large district pass

forced through a pile of sheets by mean This shape is not now in to

it serves as an example of some of the attempts which have been made to give additional security with an improvement of appearance and siyle. The cut pieces are gummed on one side at the ends of each flap, and when folded

indicated by the dotted hnes in the plan of the cutter, the cutter, the long narrow part adheres to one end of the counterflap, which thus forms the back, and the remaining

Fig 3. pair of flaps fold down upon the former This shape sale of flaps fold down upon the former. This shape of envelope has never come into general use. In 1865 a folding-machine for completing the envelopes was invented by Mesers. Edwin Hill and Warren De la Rue, London It produces about 25 folded envelopes per minute, or in a working day of ten hours, 25,200. The blanks are said by hand upon a table carrying a metal frame, the interior of which exactly corresponds in size and shape to the finished envelope, and immediately over fits is a box or plunger, which, fitting to the interior of the frame, is caused to descend upon the proper blank when laid over it, thus creasing it on all four sides, as will be understood on examining a partiallyblank when lead over it, thus creasing it on all four ades, as will be understood on examining a partially-opened envelope the box then opens to admit of a partial folding. In this condition the blank has been simply creased, and the four flaps stand up at right singles to the plane of the sheet. Before the creasing-box is entirely raised, two of a set of folders, placed one can each of the four sides of the frame, come for-ward, and meas down the two flars corresponding to ward, and press down the two flaps corresponding to their elitation, and the remaining two folders come into action to press their two fisps after the other por-tion of the plunger is raised These movements comtion of the plunger is raised. These movements complete the envelope by turning down the right angle lage to the plane of the sheet, and the next step is to sensore them from the folding-frame. For this purpose two finger-shaped projections of caoutchouc are made use of; and, owing to the strong adhesion existing between this substance and paper, the folded envelopes are quickly removed as fast as they are produced. The twenty-two movements required in folding-each envelope are performed rapidly and noiselessly, principally by various adaptations of cams. Prior Messes, Mill and De la Rue e invention, the only facilitation of manual labour in folding was obtained by the use of a species of tool which partially creased the mesers, him and he is true a invention, the only facilitation of manual abour in folding was obtained by the use of a species of tool which partially creased the blanks, leaving them to be durined up and finshed by band. Compared with "the results of machinery," the hand labour, although in itself an astoniahing instance of practical dexterity, is inordinately slow. Cirls are always employed in this work, and a first-rate hand can field and gum for use from 3,000 to 3,500 per slay, or from 5 to 6 per minute, the average personnesses being from 2,500 to 3,000. To serve as this particular size or eight munths' practice is required. By sinchar comparative statement we find that in unstanged diveleges, hand labour, 6 per munte, 10 hours per slay = 3,500, the work of one girl. Stamped envelopes, hand labour, 45 per minute, 10 hours per slay = 2,500, a sing's work; the time being divided into 7 hours for folding and gumming, and 3 for stamping. On Plates Li, and Lill, and in the secondarying figures, very full details use given of an improved folding-insolute patentics in the year 1853, by 3L. Bémend.

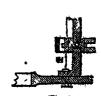

Fig. 7. Pie 8.

Fig 6. Fig. 7. Fig 8. movements on the man shaft (A) of the machine. The arrangement of the mechanism is such that a quantity of blanks of the required size being placed on the feeding-table, each will be taken up singly from the pile and fed into the feeding apparashs by means of an instrument, in which, at proper intervals, a partial vacuum is formed, whereby each sheet is sucked up against the surface of the fingers for conveyance to the folder. The first step of the process of folding is accomplished annilarly to the mode hitherto adopted and generally explained in reference to Mesers De is Rue's machine; that is, the flags of the blanks are bent to a right angle by the same means; but a novel arrangement is introduced for the performance of the secondary fold. The hottom of the creasing-frame, or box, is perforated as that the passing back of the plunger leaves the blank within the recess with its four flags standing upright; and here the second application of the standards. and here the second application of the samesh action comes into play for the purpose of giving flaps a preparatory inclination inwards, in ords and here the second application of the samespassic solution comes into play for the purpose of giving the flaps a preparatory inclination inwards, in order to fit them for receiving the flat folding pressure of the return stroke of the plunger. To this end the index of the folding-box are perforated so as to allow streams of air to be forced against the outside of the flaps, so that on the descent of the plunger they will be folded down at ones, the interior and under side of the plunger being so formed as to cause the flaps to succeed each other in proper order. In addition to this, certain contrivances are adapted for examping the outer flaps with an emboused or performed design, and also for gumming the lowest flap as a fastening for the finished envelope. A is the main driving-shaft, whol gives motion to the machine. It carries at one end a fast-and-loose driving pulley, and at the other a fir-wheel, to assist in regulating the movement; and its intermediate portion is fitted with seven came, for communicating motion to the different working parts B is the folding-loc, or receive, in which the folding process is performed. It consists of four side-pieces, at the angles of which are projections (C O ), between which the blanks are successively fed, so that they may be correctly placed and held disting the action of the plunger. D is the door or movelable bottom of the box, hinged at one end, so that first and the proper time of the country of the came of the man of the love of the plunger. But he had it may be discharged below. It is perforated with numerical levies, for the escape of air, as the hank is forced down, and a kept disclosed by means of a lever [3], which is activated at the proper intervals of time by these of the same flat as the program of the same flat, gring motion to a side-fif.

## Envelope-making

connection with the same number of came. The slide works between two fixed guiding surfaces (H H), as detailed in figs. 6 and 7, and has at its upper and a small antifriction roller, kept my in cointact with its actuating cam by the elastic tension of 8 hand of valcanized india-rubber. The lower end of the slide preases on the end of the sranked lever H, the other and of which rests against the under surface of the movable door D, so that the latter is kept closed during the proper position of the revolution of the main shaft. The feeding action is accomplished by the exterior cam (K) on the shaft giving motion (as before explained with regard to the cam F) to its slide L, which is attached to the aborter end of the cranked lever M, the opposite arm of which is jointed by connecting rods to the feeder N. This instrument is carried upon a slide having dovetailed edges, moving between fixed guiding dovetaile at O.O. It consists of two hollow flugars (P, P), each having an opening on the under side; the interior of the flugars opening into the healter position of the slide (shown by detailed). on the under side; the interior of the fingers opening into the hollow portion of the slide (shown by dotted into the hollow portion of the slide (shown by dotted lines), allowing of a partial recumn being obtained within the fingers when the exhaust movement comes into use. A flexible tube (Q) of valcanized indiarribher is attached to the under side of the slide, the opposite end being connected with the bellows (R), which receive motion at the required intervals from the cam S acting on the slide T, in connection with the best lever U, carried by a pillar at the back of the machine. The longer end of this lever is jointed by a connecting-rod (V) to the front plate (W) of the horizontal bellows, running on gride solubles (X, X). horisontal bellows, running on guide spindles (X, X). In this way, when the under side of the fingers comes In this way, when the under side of the ingers comes upon the top of the pile of blanks at Y, the orhausing action is brought into play, and the top sheet is carried over to the top of the box B for deposit, with tas angles fitting the corner guide-pieces, us in plan at fig. 3, Plate LILL. At the termination of the outward stroke of the bellows, the sheet is separated from them by the action of a valve in the bellows, opening outby the action of a valve in the bellows, opening out-wards at the commencement of the return stroke. The platform (Y) carrying the pile of blanks is made to rise and fall to suit the feeding action by a mechanical cal arrangement, worked from the cam Z. This cam-actuates a slide (a), from which an arm (b) descends for connection with the long lever (c) at the bottom of the framing, the opposite end of which is jointed to a projection on the vertical spindle (d) of the platform. To compensate for the continual decrease in the height of the pile of blanks, so that the upper one may always come in contact with the lifting-fingers when the platform rises, an india-rubber spring (e) is added, its action being to keep up the platform in contact with the fingers, when permitted to do so by the actuating cam. As everything depends upon accuracy of set, it becomes of the first importance to place the blanks in the exact position intended; and, to facilitate this, four projecting arms, or guides (f, f), are formed on the top of the platform, agreeing, as in the angle-pieces of the folding-box, with the angles of the flat blanks. As the blanks are fed into proper position, the folding-plunger (g) comes into action. This is a the platform rises, an india-rubber spring (e) is added. the folding-plunger (g) comes into action. This is a hollow rectangular metallic frame, carried by a slide the folding-planger (g) comes into action. This is a hollow rectangular metallic frame, carried by a slide (h) receiving motion from the cam R. It has in its interior a set of three projections, which, in the accordary motement, act on the separate flaps, folding them all down at once, when they are held in the required inclined position by the atmospheric side-currents, as previously explained. The inclined projections are essentially necessary in order that the laps may be folded down in their proper relative positions. The projection is pressing upon one of the side-shape accuses it to be folded first; afterwards, the projections makes upon one of the ends, whilst the third (s) carries stown the opposite one, the final folding ledge completed by the moder edges of the plunger, which gives a sharp pressure to the initiatory fold of the whole series. By suitably setting these projections, any order may be given to the flaps; thus, if the two end once do not overlay seal of there, they may be folded down together by equal projections. The detailed figures (8 and 18) substitute the intermediate stages of the plunger's folding section. Fig. 9 is a longitudinal covertion of the splunger and the pool of the folding-box in the position taken up after the first action of

# Envy

the former, the side air-passages for inclosing the disps being at 0, 0, 0. Fig. 10 is a longitudinal section of the same parts, taken just as the plunger is about

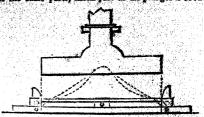

Fig. 9.

to descend in its secondary movement to give the completing fold. The necessary atmospheric side-pressure on the flaps is obtained from the inclined air-

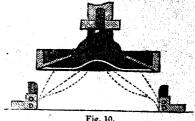

Fig. 10.

pump (p), the piston of which is driven by a crank-pin on the fly-wheel; and a tube (q) conveys the fonced are from the bottom of the pump to a hollow channel passing all round the edges of the folding-box, as dotted in the plan, fig. 3, Plate LII., whence the crifices already pointed out open inwards to the box. For the application of gum or other cementing fluid to the lowest flap, to secure the three extationary ones, a fountain is placed at r, from the bottom of whigh two twees (S, S) branch out to the two flat twollar receptacles (t, t) inclosed in a vessel (u), the supply being regulated by a stopcock before the junction of the two supply branches. The gumming action is performed by pieces of sponge placed in the upper ends of the flat tubes (s), which, standing slightly above their upper edges, the presser the edges of the lowest flap upon the plunger, presses the edges of the lowest flap upon the sponge, as clearly illustrated in the plan riew. This presser receives its motion from the came wasting on the slide x, to which the presser is attached. If it is intended to stamp or emboas the outer flap, dies are applied at y and x. The die (y) being attached to a slide (1), acted an by an external cam (2), the stamping action takes place just before the descent of the plunger. This machine produces easily 60 envelopes per minute, or 36,000 a day, completed, gummed and stamped. As at present practiced, in their modes of production, these three processes are distinct and separate, each one requiring a different handling. Thus M. Rémond's machine saves more than one-third of manual labour. The separation of the stages of the escond rank, being intenior to an ambassador. In already pointed out open inwards to the box. the cost of production, mainly in the removals.

E \*\*vor, en'-voi (Fr. encoye), a diplomatic agent of
the second rank, being inferior to an ambassador. In
common with ambassadors, they are accredited direct
from one sovereign to another; but they differ from
the latter in not representing the personal dignity of
their sovereign, but only his affairs. They are either
ordinary or extraordinary. (See Rangasz, Amassanor, Diplomatr.)

ordinary or extraordinary. Low camesas, camesas-nor, Diplomacy.)

Envy, ov-ce (Fr. envier), in Bithies, is defined by Looke to be an uncerings of mind, operationed by the consideration of a good we discover in the persession of another person, whom we design less worthy of it than ourselves. It is characterized by a degree of

sorrow that the good contemplated should escape ourselves, and of anger that it should fall to the share of another. It differs from emulation, which is merely a desire to become possessed of something which is enjoyed by another; whereas, in enry, there is a malevolent feeling which desires that others be brought down below our own level. Though the difference between emulation and enry is thus marked, through the natural weakness of our nature it is attacked. Efficient to present the former wholly and extremely difficult to preserve the former wholly un-mixed with the latter. "Pure envy," says Dr. Reid, "is the most malignant passion that can lodge in the breast, which devours, as its natural food, the fame and the happiness of those who are most deserving of our estcem.

our estem."

EOCENE, &'-o-sene (Gr. sos, the dawn; kainos, recent), in Geol., a term introduced by Lyell to designate the lower tertiary strate, from the idea that the very small per-centage of still existing species among the fossils of these strate indicates what may be regarded as the dawn or commencement of the present condition of Creation. (See Tertiary System.)
EOLIAN HARP. (See ÆOLIAN HARP.)

EFACHIDACEE, ep. a. krid ai se-e (Gr. epi, upon; akros, the top), in Bot., the Epacris fam., a uat. ord. of dicotyledonous plants in the sub-class Corollifora. The dieotyleaconous plants in the sub-class corouspiors. The species are shrubs or small trees, natives of Australia, the Indian archipelago, and the South-Sea islands, where they are very numerous. There are 31 genera, and about 320 species. They are of little importance, except for the beauty of their flowers, on which account them can make subtracted. The familia of more are additionally approximated. they are much cultivated. The fruits of many are edi-ble; as those of Astroloma humifusum, the Tasmanian eranberry, and Leucopogon Richei, the native current of Australia.

EPACT, e'-pakt (Gr. epaktos, additional), the name given to the moon's age at the close of the year. The epact of the fictitious or ecclesiastical moon, by which Easter is regulated, is given in the table of movable feasts appended to the calendar in the Book of Com-

mon Prayer.

EPAULEMENT, e - pawl' - ment (from Fr. épaule, shoulder), the name given to a species of low para pet without a banquette at its foot in the interior which is thrown up as a means of protection, and used in the construction of field-works. The expression is in the construction of held-works. The expression is often applied to a parapet of the usual height, regularly fermed, with a banquette, and may be almost considered synonymous with the term parapet. It is, however, more properly employed to designate a mound of earth, about seven or eight feet high, thrown up on either side of a battery, towards the rear, in a direction at right angles to the face, to protect the guns and more term as a rediction for the control of the seven considering the control of the seven as a rediction for t

and men from an enfolding fire.

ERAULETE, ep'-o-let (Fr.), an ornamental badge worn upon the shoulder by military and naval officers and men in the English and continental services. These distinguishing marks vary in shape and richness ne-cording to the rank of the wearer. A few years ago the epaulette was abolished in the English army, the sash being substituted for it.

EPHRMINA, e-fem-e-ri (Gr. cpi, ong emera, a day), a gen. of neuropterous insects, helonging to the fam. of Subulicornes of Latreille. They have long, soft, tapering bodies, terminating in two or three long acte. Their wings are placed nearly, or quite, perpendicu-larly; their antennæ are three-pointed, and very small, In the larva state they live in wet places, or under water, and enjoy an existence of two or three years; but when they attain their final stage of metamorphosis and perfect form, they are among the most fleeting of living creatures, existing often only a few hours, and propagating their species before they die. In this state they sometimes appear suddenly in myriads during time summer evenings by the water-side, when they may be seen flitting about, and belancing themselves in the air, in the manner of gadflies.

EPHESIANS, EPISTIE OF PAUL TO THE, of e' châus, is the fifth in numerical order of the fourteen epistles

the Ephesians," in a few of the ancient MSS., and the assertion of Marcion, a herefu of the second century, but whose testimony is of no weight, that it was addressed to the Laodiceans. Others, again, regard it as a cyclical epistle addressed to no particular church, but to all, though Ephesus may have been the chief. Though the testimony against the received opinion were much stronger than it really is, it is not a matter of great importance; for what was addressed to one was intended for all. It is generally believed to have been written about the year 81 A.D., during the early part of the apostle's first imprisonment at Rome. "He was appre-ensive lest advantage should be taken of his confinement to unactile the minde of Ephesian of his confinement to unsettle the minds of Ephesian converts, who were almost wholly gentiles. Hearing, however, that they stood firm in the faith of Christ, he wrote this epistle in order to establish them in that faith, and to give them more exacted views of the love of God and of the excellency and dignity of Christ; and at thesame time to fortify their minds sgainst the scandal at the same time to fortify their minds against the scandal of the cross. With this view, he shows them that they were saved by grace; and that, however, wretched they once were, now they had equal privileges with the Jews. He then proceeds to encourage them to persevere in their Christian calling, by declaring with what steadfastness he suffered for the truth, and with what steadfastness he prayed for their establishment and continuance in it; and urges them to walk in a manner becoming their profession, in the faithful discharge both of the general and common duties of religion and of the special duties of particular relations." The style of this epistle is exceedingly animated, and corresponds with the state of the apostle's mind at the time of this epistle is exceedingly animated, and corresponds with the state of the apostle's mind at the time of writing. Overjoyed with the account brought him of their faith and holiness, and transported with exalted views of God's love and goodness, more especially in conferring the benefits of Christ's death upon the gentiles, his thoughts soar high, and tind utterance in sublime and copious expressions.—Ref. Horne's Introduction to the Sacred Scriptures.

Expressions.—Ref. Horne's the

Introduction to the Sacred Scriptures.

ETHPHEGUS, e-pi-fe'-gus (Gr. epi, upon; phegos, the beech), a gen. of plants parasitical upon the beech-tree.

ETHOD, ef'-od (Heb., a covering), among the ancient Jews, was one of the essential articles of the priest's official dress. It was an upper garment consisting of two pieces, one covering the back and the other the breast, and being united upon the two shoulders. It was made of plain linen, except that of the high priest, which was embroidered with various colours. Properly, according to the law of Mosses, the ephod was to be worn only by the high priest; but it subsequently came to be in common use among the oriesthood, and to be worn only by the high priest; but it subsequently came to be in common use among the priesthood, and even David, when bringing the ark back to Jerusalem, appeared in one. The ephod was regarded by the Jews as a sacred object, and sometimes received divine homage. A description of the ephod of the high priest is given in Exodus xvviii. 6, et seq.

EPROSI, of 'o-ri (Gr. ephoroi, overseers), magistrates who were common to many Dorian constitutions in auction of anything to Lorange which arise the least the control of the latest the expense which arise to search the services are the services as the service of the control of the least the services are the services as the services are the services are the services as the services are the servic

tion of ephori to Lycurgus, while Aristotle ascribes it to Theopompus, who lived about 770 B.C. Both these to Theopompus, who lived about 770 s.c. Both these accounts, however, seem to be incorrect, the real origin of the ephori being lost, through historical inaccuracy and varieties of opinion. The duties of the ephori consisted in the management of the internal administrations of the state, especially matters of justice; and a particular building, called the Ephorion, was allotted to them. The number of the ephori was five; they were elected from and by the people, and held their offices for one year. Those who had votes in the election were not restricted by age or property, so and the election was not not under any scrutiny; so in the election were not restricted by age or property, and the election was not put under any scrutiny; so that, as Aristotle observes, in the institution of the ephori, the people participated in the highest magistracy of the state. In later times, the powers of the ephori were greatly increased. They had the privilege of instituting scrutinies into the conduct of all the magistrates, and are the hings could be branched. is the fifth in numerical order of the fourteen epistles of St. Paul contained in the canon of the New Testament. The principal fathers of the early Church are numerical manimous in favour of the genuineness and canonicity under their authority, and it could not be said when the could not interfere. At last, quently been carried on as to whether it was addressed in 255 s.c., the ephori for the time being were murto the Ephesians, from the omission of the words "to dered by Agis and Cleomenes, and the office abolished."

## Epicalyx

The ephori were, however, again restored to power

under the Komans.

EFICALYX, ept-e-kai-like, in Bot., the term applied by many botamist to a circle of bracts appearing immediately below the calyx or outer covering of the flower. It is seen in the mallow tibe, and in many plants of the pink and rose tribes. Though a distinct same has been given to this whorl of leafy organs, it properly comes under the denomination of involuers (which see). (which see).

(which see).

EPICARP, ep'-s-karp (Gr. epi, upon; karpos, fruit), in Bot., the external layer or region of the pericarp or shell of a fruit. This layer generally appears as a thin skin, being far less liable to alteration than either mesocarp or endocarp. (See FRUIT.)

EPIC PORTEN, ep'-ik (Gr. epos, a discourse or narrative), is a kind of poetry which has outward objects for its subjects, and is thus distinguished from lyric poetry, which deals with the inner feelings and emotions of the mind. The distinction is general; for there are few norductions to which it can strictly apply; but are few productions to which it can strictly apply; but they belong to the one class or the other, according to the predominating character. As in the individual man, so with the human race, the mind is objective before it is subjective; it observes external objects before it turns its thoughts in upon itself; and hence we may conclude that the epic was the earliest species of poetry. The earliest specimens of this form of art probably consisted of simple tales rhythmically arranged, and recited to a very simple musical accom-paniment. The longer and more artistic epic poems, however, embrace an extensive series of events and however, embrace an extensive series of events and the actions of numerous personages. The epic poetry of the early Greeks naturally divides itself into two classes,—the heroic or romantic epos of Homer, and the hieratic epos of Hesiod, the one dealing with the political, the other with the religious, life of the Greeks. The "Hiad" and "Odyssey" of Homer present us with the finest specimens of this class of poetry that have ever appeared. The sacred poetry of Hesiod partakes very much of a lyrical character. The "Æneid" of Virgil is not equal to the "Iliad" of The "Encid" of Virgil is not equal to the "Iliad" of Homer as an epic; its superiority depending more on beauty of language and arrangement than on anything in the story. The greatest epic of modern times is the "Paradise Lost" of Milton. Dante's "Divine Comedy," however sublime in style, is destitute of that unity of event or action necessary to constitute a great work of this class. The "Jerusalem Delivered" of Tasso is regularly and strictly an epic, and adorned with all the beauties that belong to this species of composition. The epic poem is of all poetical works the most dignified, and at the same time the most difficult in execution; and hence it is that so very few the most dignified, and at the same time the most difficult in execution; and hence it is that so very few have succeeded in the attempt to produce a really great epic. "To contrive a story which shall please and interest all readers, by being at once entertaining, important, and instructive; to fill it with suitable incients; to enliven it with a variety of characters, and of descriptions; and throughout a long work to maintain that propriety of sentiment and that elevation of style, which the epic character requires, is unquestionably the highest effort of poetical genius."—(Blair's Ratorio.) It requires, more than any other species any one nigness enors or poetical genua."—[Blair's Rhetoric.) It requires, more than any other species of poetry, a grave, equal, and supported dignity. The action, or subject, must have three properties: it must be one; it must be great; and it must be interesting. Scattered and independent facts can never affect a reader as deady was accomplished. esting. Described and independent acres as a strongly, as a tale that is one and connected, where the several incidents hang upon one another, and are all made to conspire for the accomplishment of one end. Such episodes or subordinate actions as are introduced should be brought in naturally, and have sufficient connection with the principal subject; they ought to be elegant and well-finished, and present us with objects of a different kind from those that go before objects of a different kind from those that go before or follow after. Epic poetry has often been compared to the drama; and the essential difference between the two is, that the province of the former is description; of the latter, action. The smotions which epic poetry excites are not so frequent and violent as those produced by dramatic composition, but they are more prolonged and more developed by actual occurrences; for an epic poem embraces a widst compass of time

# Epidermal Appendages

and action than is admissible in the drama. Epic poetry "is the region within which we look for everything that is sublime in description, tender in sentiating that is sublime in description, tender in sentiating that is

thing that is submitted in expression;" and "all the objects which it presents ought to be either great, or tender, or pleasing."—(Blair.)

EFICUREATION, ep-s-ku-re'-da-icm, a term applied to the system of philosophy adopted and promulgated by Epicurus, who lived from B.C. 337 to B.C. 270. In its character assume that the system of philosophy adopted the universe, who lived from B.C. 337 to B.C. 270. expectures, who lived from B.C. 337 to B.C. 270. In its physical system encureanism considered the universe, consisting of matter and space, to be infinite and eternal, while the various bodies of which it is composed are subject to decay and change. "Nothing can spring from nothing, nor can anything return to nothing," was one of the favourite maxima of the school. The science of the statement of the statement of the school. nothing," was one of the favourite maxime of the school. The science of physics was, however, in the opinion of Epicurus, subordinate to that of ethics. According to his authority, the great end of man is his own happiness, which is to be obtained by the subjugation of his passions and the moderation of his desires. His followers entering farther into the spirit and natural tendency of his system, resolved all hap-piness into the gratification of the senses. The sys-tem was consequently adopted readily by the idle, the luxurious, and the vicious. At the present day epicu-reanism in its physical system is synonymous with the doctrine of chance, and in its moral system with selfishness.

EPIDEMIC, ep-s-dem'-ik (Gr., from epi, upon, and demos, the people), in Med., is a general term applied to diseases which provail among a large portion of the to diseases which provail among a large portion of the people of a country or place for a certain time, and then gradually disappear. The causes assigned for the prevalence of epidemic diseases are very various, and are by no means determined. The most generally assigned causes are a peculiar state of the atmosphere or climate, the seasons, &c. Defective ventilation or drainage, and unwholesome food or drink, are also among the causes that induce epidemics. Most epidemic diseases are likewise contagious, and thus, when once induced, spread with great rapidity. During the prevalence of an epidemic, it is proper to take particular care of the health, as the best means of resisting

its influence

its influence.

RPIDEMALAPPENDAGES, ep-e-der'-mal ap-pen'-dāj-es
(Gr. epidermis, the cuticle; Lat. appendo, I hang or
attach to), in Bot., the general term for certain structures, consisting of cells, variously combined, found
upon the surface of the epidermis, or in the subepidermal tissue. They may be divided into hairs and
glands. The former are thread-like elongations, externally, of the epidermal cells, covered by cuticle.
When a hair is formed of a single cell, it is said to be
simple; and when composed of several cells, compound. hairs appear under a variety of forms: thus they may be undivided, branched, or forked; star-shaped, or stell-ste; necklace-shaped, or moniliform; club-shaped, stellate; necklace-shaped, or montifform; club-shaped, or clavate; shield-like, or peltate. They-sometines are found terminating in a hook on one side pointing downwards, when they are said to be uncinate; and sometimes they present two or more hooks at their aper, when they are said to be glochidiats, or barbed. When the divisions of a stellate hair are closely connected, a scale or scurf is formed. When hairs are composed of cells which are short, and have their sides thickened by secondary denomina as that they form composed of cells which are short, and have their sides thickened by secondary deposits, so that they form stiffened processes, they are then called seta, or bristles. These, slightly modified, form prickles, which are defined as large hardened processes, terminating in a sharp point, and springing from the epidermis, or the bark of plants. They are especially abundant on the stems of the rose and bramble. Hairs occur upon various parts of plants, and, according to their abundance and nature, give varying appearances to them, which and nature, give varying appearances to them, which are distinguished in practical botany by special names. The more common position of hairs is upon the leaves and stems; but they also occur on the parts of the flower, the fruit, and the seed. The substance called cowage, or cowrich, is the hair covering the legumes of Mucuna pruviens, while cotton is simply the hair covering the seeds of various species of Gosspius. covering the seems of various species of Consystems. Glands, properly so called, are cells which secrete a peculiar matter; but with them botanists generally associate other superficial appendages. The sting of the nettle, the little receptacles in the rind of the

# Epidermal Tissue

orange, and the necturies at the base of the coloured leaves of the buttercup and crown imperial, are familiar examples of glands. When glands are situated below the epidermis, and surrounded by a compact layer of cells, they are said to be internal. These are common in such plants as rue, mint, majoram, and thyme; and it is to the presence of the scoretions they contain that the plants owe their value as articles of comestic economy or medicinal agents.

EPIDERMAL TISSUE, in Bot., the termed applied to the external layer of cells in flowering and the higher flowerless plants. This layer may commonly be readily separated as a distinct membrane or skin, as its component cells differ in shape and in the nature of their contents from those cells placed beneath them. This tissue consists of two parts; namely, of an inner portion, usually called the *epidermis*, and of an outer thin pellicle, to which the name outicle is given. Carpenter, and some other authors, make use of these terms in and some other authors, make use of these terms in precisely the reverse sense, calling the external pelli-cle the epidermis. We, following Professor Bentley, will employ the terms as generally understood. The epidermis, then, consists of one or more layers of cells, epidermis, then, consists of one or more layers of cells, firmly united together by their sides so as to form a membrane. These cells are generally of a flattened tabular character; but they vary much in their outline. Ordinarily, in European plants, the epidermis is formed of but one row of cells; but in tropical plants, two, three, or more rows are common. The upper walls of the cells are generally much thickened by secondary deposits, and this thickening is especially avident in leaves of a leathery or hardened texture. evident in leaves of a leathery or hardened texture, as those of the cleander, box, and holly. The epidermis covers all parts of the plants upon which it is found that are exposed directly to the air, except the stigma; and it is in all cases absent from those which live under water. In the fungi, algae, and lichens, it is altogether wanting. The cuticle covers the entire is altogether wanting. The cuttele covers the entire surface of the epidermal cells, with the exception of the openings called stomata, and even sheathes the hairs and other appendages. It has no cellular structure, but is a perfectly homogeneous membrane. A membranous layer, resembling, if not actually identical with cuticle, is found upon the surface of plants living under water, and also covering the algae, lichous, and fungi. The stomata, or stomates, to which allusion has been made, are oritices situated between some of the been made, are orifices situated between some of the epidermal cells leading into the intercellular cavities beneath, so as to allow a free communication between the internal tissues and the external air. They are commonly called breathing-pores. They vary in form and position in different plants and different parts of and position in different plants and different parts of the same plant; but they are always the same in any particular part of a plant. The most common form is oval, but they are sometimes seen round or square. They are either placed singly upon the epidermis at regular or irregular distances, or in clusters, with spaces quite free from them intervening. The number of stomata also varies considerably in different plants and different parts of the same plant. We give the numbers counted in a square inch upon the upper and under surfaces of the leaves of a few plants, to show the extent of this variation:—Mislatore, upper surface under surfaces of the leaves of a few plants, to show the extent of this variation:—Mistletoe, upper surface 200, under surface 200; prony, upper surface none, lower surface 13,710; house-leek, upper surface 10,710, lower surface 6,000; liliac, upper surface none, lower surface 160,000. Stomata exist more or less upon all flowering plants, but are absent from the lower orders of flowerless plants. On floating leaves they are only found on the upper surface.

EPIDERMIS. (See SEIN.)

EPIDERMIS, in Bot. (See EPIDERMAL TISSUE.)

EPIGEOTTIS, ep-e-glot'-tis (Gr. epi, upon, and glotta, the tongue), in Anat., is the cartilage at the root of the tongue that falls upon the glottis, or superior opening of the larynz. In figure, it is somewhat oval, rather of the larynx. In ngure, it is somewhat oval, rather convex above and concave below, and covered by mucous membrane. It adheres inferiorly to the interior part of the thyroid cartilage by a strong elastic membrane. Its apex is loose, and always elevated upwards by its own elasticity. When the back of the tongue is drawn backwards in swallowing,

the epiglottis is put over the aperture of the larynz, and thus shuts up the passage from the mouth into

the larynx.

# Epilepsy

EFIGRAM, ep'-e-grām (Gr. epigramma, an inscription), a term originally applied, as shown by its derivation, to the inscriptions on the tombs and monuments of the ancient Greeks. They were generally written in verse, and showed great simplicity of style. Usually they were either dedicatory, descriptive, amatory, or elegiac. They were seldom humorous; and their chief marrit consisted in the justness of a single thought conenergiac. They were season numerous; and their ones merit consisted in the justness of a single thought conveyed in harmonious language. The nucient Romans, in their acceptation of the term epigram, seem to approach nearer to the idea of modern epigram. Catullus proach nearer to the idea of modern epigram. Catulus and Martial were amongst their most famous epigrammatists. In modern times an epigram is considered to be a short poem usually consisting of two to eight lines, in which some striking or ingenious thought is expressed; whether it be serious or humorous is a matter of indifference. The French have always could in the literature of the french have always excelled in this kind of writing. The Germans have usually combined moral proverbs with their epigrams; but those of Schiller and Goethe are generally satirical. Pope, Byron, Burns, and Moore, in this country, have written epigrammatic satire with the greatest success. The following lines, written by Voltaire, under a statue of Cupid in his garden, may serve as a specimen of the modern epigram :-

> Qui que tu sois, voilà ton maître,-Il l'est, le fut, on le doit être." Whoe'er thou art, thy master see,-He is, or was, or is to be.

He is, or was, or is to be.

EFIGXNOUS, e-pij'-e-nus (Gr. epi, upon; gune, female), in Bot., a term applied to the stamens and corolls when they appear to arise from the summit of the ovary, in consequence of the adherence of the calvax to that organ. Examples may be seen in the campaunia, carrot, and ivy. The name Epigona has been given to a subdivision of the Calycilvar, and also to a subdivision of the Carollifora, from the calva being more or less adherent, and the ovary consequently inferior. (See classification in article BOTANX.)

EPILEPSY, ep'-e-lep-se (Gr. epitepsis, from epi, and lambano, I seize), in Med., is a form of disease which receives its name from the suddenness of its attack. It is also called the falling sickness, from the patient.

It is also called the falling sickness, from the patient, if standing, suddenly falling to the ground. By the ancients it was called the sacred disease, from being supposed to be due to the influence of the gods or evil supposed to be due to the influence of the gods or evil spirits. The attack is usually sudden, without any warning. The patient may be in his ordinary health, engaged, perhaps, in his usual occupation, when all at once he utters a pieroing scream, and falls to the ground. Immediately thereafter the face becomes violently distorted, the head is usually drawn to one side, the eyes are set and staring, or roll wildly about, the colour of the skin becomes dark and livid, and the rains awallan and thereid there is frothing at the veins swollen and turgid; there is frothing at the mouth; the muscles of the lower jaw act violently, producing gnashing of teeth, and frequently the tongue is thereby grievously injured; the arms are sometimes thrown violently about, and the lower limbs may be thrown violently about, and the lower limbs may be agitated in a similar manuer, while the fingers with great power clutch at whatever comes in their way. The breathing is at first heavy and difficult, but afterwards it becomes short, quick, and stertorious, and is often accompanied with signing and meaning. One side of the bedy a numeral of the state of of the body is commonly more agitated than another. of the body is commonly more agitated than another. After a longer or shorter period, the convulsive movements gradually diminish, and the patient seems to recover a faint glimmering of consciousness; but the look which he casts around is stupid and heavy, and he goes off into a lethargic sleep, from which he does not awake for some hours. Commonly there is no consciousness of anything that occurred during the paroxysm. On conjugate the fit there is generally paroxysm. On coming out of the fit, there is generally headache, and always languor, and it may be days before he fully recovers from the effects of the attack. before he fully recovers from the effects of the attack. The duration of the paroxysm is usually from five to ten minutes; but sometimes several attacks follow each other, and it may be protracted for several hours. This is a severe form of epilepsy; but frequently it is less severe, consisting merely of loss of consciousness, slight rigidity, and the convulsion of a few muscles, and lasting only for a minute or two. Occasionally death takes also a device the processor in the convulsity is a standard. place during the paroxyam; but generally it is attended with little danger unless the patient may injure himself

by falling in some dangerous position. During the attack, the principal thing is to see that the patient do not injure himself,—especially, a piece of cork or other gag ought to be placed between his teeth, to prevent injury to the tongue: the dress should be loosened about the neck and chest; the head, if possible, a little raised, and a free circulation of air maintained. The return of the fit is exceedingly surjoined. tained. The return of the fit is exceedingly various in different individuals; several years, in some cases, intervening between the attacks, while in others they may occur every month, week, or day. When neglected, they usually become more and more severe, or recur at shorter intervals. Repeated attacks of this disease, in general, soon produce a marked change in the mental and physical character of the individual. There is a gradual diminution of the active powers, purpose begradual dumination of the active powers, purpose becomes irresolute, the spirits are depressed, and the memory fails; the features become coarse, heavy, and inexpressive, and the look vacant. The most frequent, perhaps, of the consequences of confirmed epilepsy is insanity, either in the form of acute mania or monomania following the attacks, or of gradual imbedility, without any acute seizure. Though the fit, as we have without any acute seizure. Though the fit, as we have said, usually comes on suddenly, yet there is sometimes distinct warning of its approach. These vary in dif-ferent individuals, and may be lowness of spirits, irrirerent mutvialus, and may be lowness of spirits, irritability, dizziness, noises in the car, floating specks before the eyes. There is, however, a particular sensation which is said to be felt by some immediately before the attack, and which is known as the aura epileptica. It is variously described as resembling a current of air, a stream of water, or a slight convulsive tremor, commencing in one of the limbs, and proceed ing upwards to the head, when the patient is deprived of all consciousness. Epilepsy is commonly divided into idiopathic, when it is a primary disease, depending on some affection of the brain, and sympathetic, when on some affection of the brain, and sympathetic, when produced by an affection in some other part of the body,—as the stomach, bowels, liver, circulating system, &c. Among the causes which give rise to epilepsy are external injuries done to the brain by blows, wounds, fractures, and the like, or internal injuries by water in the brain, tumours, concretions, and polypi. Violent affections of the nervous system, sudden frights, strong mental emotious, acute pains in any part, worms in the stomach or intestines, teething, suppression of accustomed exacustions &c. are causes suppression of accustomed evacuations, &c., are causes which also produce epilepsy. Sometimes it is hereditary, at other times it arises from a predisposition occasioned either by plethora or a state of debility. When it arises from hereditary predisposition, or comes When it arises from hereditary predisposition, or comes on after the age of puberty, or when the attacks are frequent and of long duration, it is usually difficult to effect a cure; but occurring in early life, and occasioned by worms or any other accidental cause, it may, in general, be remedied with ease. Where the disease can be traced to any special exciting cause,—as injuries of the head, worms, teething, &c., the treatment should be first directed to its removal. Where, as is often the case, a plethonic attacks means to occasion the disease. the case, a plethoric state appears to occasion the disease, the patient is to be restricted to a low diet, frequent purgatives are to be exhibited, and everything avoided that may determine the blood to the head; and to counteract such a tendency, occasional cupping, blisters, issues, &c., may be useful. If, on the contrary, there are marks of inantition and debility, a generous distantial tools madicines and other means of streamth. diet, with tonic medicines and other means of strengthening the system, will be proper. In this disease great care is necessary in the matter of diet, and moderation in quantity and simplicity in character are material points. When the appropriate remedies are judiciously employed, and the proper regimen strictly adhered to, opplepsy is often permanently cured, and the suffering is greatly mitigated even in those forms which do not admit of cure.—Ref. Copland's Dictionary of Practical Medicine; Cheyne's Cyclopadia of Practical Medicine. EPILOSUE, ept-s-log (Gr. ept, on or after; logos, a speech), amongst the ancient Greeks, the end or summing up of a discourse. In English, the torm is applied to the short poem, or prose address, delivered in a theatre at the conclusion of a play. It is, and has diet, with tonic medicines and other means of strength-

a theatre at the conclusion of a play. It is, and has been at all times, familiar in tone, and, except on extraordinary occasions, is mostly written in a merry vein. The intention of the epilogue is to create a kind been at all times, familiar in tone, and, except on extraordinary occasions, is mostly written in a merry vein. The intention of the epilogue is to create a kind and friendly feeling between the sofor and the audi-part of a play which lay between two choral songs.

ence; and it frequently alludes to the events, fashions, and follies of the day. One of the most charming epilogues is that spoken by Rosalind, at the conclusion of "As You Like It":—"If it be true that good wine needs no bush, 'tis true that a good play needs no epilogue: yet to good wine they use good bushes, and good plays prove the better by the help of good enilogues."

EPIPETALOUS, ep-e-pet'-a-lus (Gr. spi, upon ; petalon, a petal), in Bot., a term applied to the stamens when they are attached to the corolla, as in the primrose. This character marks the subdivision Epipetalæ or Epicorollæ, of the sub-class Corollifloræ. (See classi-

fication in article BOTANY.)

ETIPHANY, e-pif-u-ne (Gr. epiphaneia, a manifestation), a church festival held on the 6th day of January, in order to celebrate the manifestation of Christ. In early times this festival probably commanorated the nativity of the Saviour, his manifestation in the flesh, and his manifestation to the Gentiles. The service in the Church of England has reference to these three events. As a household festival, the Epiphany is better known by the name of Twelfth-night being the twelfth night from the Nativity). The practice of choosing a king and queen in family merriments upon that night has been traced back to a similar custom among the Romans during the Saturnalia.

EFIFHEGUS, ep-e-fe'-gus (Gr. epi, upon; phago, I devour), in Bot., a gen. of plants belonging to the nat. ord. Orobanchaces. The root of E. cirquinana is called cancer-root, from having been formerly used as an application to cancers. It was the principal ingredient in a once celebrated North-American nostrum,

called Martin's cancer powder.
EPIPHYTES. (See AIR-PLANTS.)

RPISCOPACY, e-pis'-ko-pā-se (Gr. episkopos, a bishop, or overseer), is that form of church government in which one order of the clergy is superior to another; as hishops to priests and deacons. Much discussion has taken place on the subject of episcopacy. Nothing conclusive can be gathered concerning it in the New Testament; but there can be no doubt that it existed universally in the Church from the earliest historic ages down to the time of the Reformation, and it is inferred, as no change can be shown to have taken place, that the same constitution existed from the time of the apostles. Presbyterians and Independents argue, on the other hand, that as there is nothing definite con-cerning it in Scripture, Christians are left a discretion-ary power of modelling the government of their church in such a manner as may seem to them most meet; and that every Christian society has a right to make and that every Christian society has a right to make laws for itself, provided these laws are consistent with charity and peace, and with the fundamental doctrines and principles of Christianity. "It cannot be proved," says Dr. Paley, "that any form of church government was laid down in the Christian, as it has been in the Jewish scriptures, with a view of fixing a constitution for succeeding ages, and which consti-tution, consequently, the disciples of Christianity would everywhere and at all times, by the very law of their religion, be obliged to adopt. Certainly to com-mand of this kind was delivered by Christ himself; and if it be shown that the apostles ordained bishops and presbyters among their first converts, it must be remembered that descons also, and desconesses, were appointed by them with functions very dissimilar to any which obtain in the Church at present. The truth seems to have been that such offices were at first erected in the Christian Church as the good order, the instruction, and the exigencies of the society at that instruction, and the exigencies of the society at that time required, without any intention, at least without any declared design, of regulating the appointment, authority, or the distinction of Christian ministers under future circumstances." The power vested in the bishops or higher elergy differs very much among the different episcopal bodies. The Roman Catholic and different episcopal bourse. The Koman Cababa and the Greek churches, as well as the Church of England, are episcopalian. (See Anglo-Catholic Church, Roman Catholic Church, Garek Church.)

#### Epistle

As these recitations in the early history of the Greek stage had nothing to do with the choral part, the term coessodion, with its Latin derivative episodium, began to be applied to any incidental narrative or digression in a poem which the poet has connected with the main plot, been when the poet has connected with the main plot, but which is not essential to it. In this light, the catalogue of ships is considered an episode in the "Hiad," and the description of the war in heaven is considered an episode in "Paradise Lost." Episodes should grow naturally out of the subject, and should either point out important consequences or develop hidden causes. The episode describing the destruction of Troy, in Virgil's "Æneid," is an episode of this kind. In the Virgil's "Æneid," is an episode of this kind. In the best poets, episodes are generally finished in the most careful and elaborate manner. The "Faery Queen" of Spenser, and the "Orlando Furioso" of Ariosto, contain so many long episodes, that the poems present all the appearance of an inartistic compilation of unconnected legends.

EPISTLE, e-pist-1 (Gr. epistole, a message or letter), is a letter written from one person to another. The Scriptural epistles are letters which were addressed by the inspired apostles to churches or individuals. Of these the apostle Paul wrote fourteen, St. James one, St. Peter two, St. John three, and St. Jude one. Those of SS. James, Peter, John, and Jude, are com monly called general or Catholic epistles, as not being addressed to any particular church, but to the churches addressed to any particular church, but to the courcies in general. It is not without its use that we have the doctrines of the Christian religion laid down, not by one apostle only but by several, so that the same divine truths are presented to us in different forms or through different media, and thus their manifold beauties and character are better displayed. In reading an epistle, we ought to consider the occasion of it, the circumstances of those to whom it was addressed, the time when it was written its general good and design. time when it was written, its general scope and design, as well as the intention of particular arguments and passages. By epistle in the liturgy is meant the first lesson in the communion-service, and so styled because it is generally taken from the sacred Epistles, though sometimes it is taken from the Acts, and occasionally from the Prophets. Almost all the lessons now read as epistles in the English liturgy have been in their present place and used by the Church for many ages. They are found in all the liturgies used before the revision in the reign of Edward VI.; and they also appear in all the monuments of the English liturgy before the invasion of William the Conqueror.

TETTATH, ep-e-tof (Gr. epi, upon; taphos, a tomb), the inscription upon a tombstone. Among the classical nations of antiquity, epitaphs were at first only inscribed upon the tombs of heroes and those who had made themselves distinguished in their country. Among the Greeks, the term was also applied to those verses which were sung in memory of a deceased person on the day of his funeral, or on its anniversary. son on the day of his funeral, or on its anniversary. Amongst the Romans, every family who consecrated a tomb to their relations had the privilege of inscribing an epitaph upon it. Both Greek and Roman epitaphs were distinguished by three qualities,—brevity, simplicity, and familiarity. The Roman tombs were generally situated by the side of the public road, and the epitaphs usually commenced with the words "Sta, viator,"—Stop, traveller. Sepulchral inscriptions seem to have first taken their origin in England in the 11th century. At that time they were always written in Latin. In the 13th century, most of the epitaphs were written in French; but the clergy and religious bodies still continued to write in Latin. English epitaphs were not written till the middle of the 14th century. The modern English, French, and lingish epitapis were not written till the middle of the 14th century. The modern English, Freuch, and German epitaphs are more numerous and varied than those of any other time or nation. They exhibit every variety of style and sentiment, from heraldic prolivity and epigrammatic conceit to majestic gravity. All epitaphs should be characterised by brevity and truth. epitaphs should be characterized by brevity and truth. The long tedious inscriptions upon some tombs are as untrue as they are ungrammatical, and would almost seem to substantiate the German proverb — "He lies like a tombstone, and is as impudent as a newspaper." Among the many famous epitaphs existing in England, may be mentioned the well-flower inscription on Sir Christopher Wren's monument in St. Paul's cathedral,

# **Epronvette**

" Si monumentum quæria-circumspice." If you ask for his monument, -look around.

The following epitaph, which is exquisitely touching and simple, was written by Ben Jonson, and inscribed on the tomb of the countess of Pembroke:—

"Underneath this sable hearse Lies the subject of all verse; Sidney's sister, Pembroke's mother. Death, ere thou canst find another Good, and fair, and wise as she, Time shall throw a dart at thee

Notwithstanding the solemn circumstances with which epitaphs are associated, they are often made the vehi-cles of pleasantry and satire. Goldsmith wrote the following upon Mr. Edward Purdon:—

"Here lies poor Ned Purdon, from misery freed, Who long was a bookseller's hack; He led such a damnable life in this world, I don't think he'll ever come back."

Burns wrote some very satirical epitaphs, and in France the same kind of grim humour has frequently been indulged in. The epitaph upon Robespierre is as

Passant, ne pleure point mon sort ; Si je vivais, tu serais mort." Dry your tears, passer by; If I lived, you should die.

EFITEALAMIUM, ep-e-thàl-ai'-me-um (Gr. epi, on; thalamos, a bridal chamber), a species of poem sung by the ancient Greeks and Romans near the bridal chamber of a newly -married couple. Poems of this character were written by Anacreon, Stesichorus, and Pindar. The epithalamium written by Catullus on the occasion of the marriage of Peleus and Thetis has always been much admired; and that written by the English poet Spencer has been described as one of the most gorgeous in all literature.

Epither. ep'-e-thet (Gr. epitheton, from epi, upon.

most gorgeous in all interature.

Epirmer, ep'-e-thet (Gr. epitheton, from epi, upon, and tithemi, I lay or place), is applied to an adjective expressing some real quality of the thing to which it is applied, or an attributive expressing some quality ascribed to it. Epithets are often used in poetry and rhetoric, not to make up any essential part of the description, but only by way of ornament. Even Homer has been found fault with on this head, for equipping every hero with an epithet, not according to the exigencies of the case, but to suit the measure of his verse. Nothing, says Aristotle, tires the reader more than too great a redundancy of epithets, or epithets improperly applied; and yet nothing is so essential in poetry as a proper use of them. Epithets are also sometimes applied as surnames, or as persons' second appellation, and were anciently bestowed very freely on account of excellencies or defects, either of body or mind,—even kings not being exempt from them; as, Edward Longshanks, Richard Cour de Llon.

them; as, Edward Longmanns, Richard Cour de Lion.

Epizoa, epe-ezo'd (Gr. epi, on; zoon, an animal), a
term applied to those parasitic animals which live
upon the bodies of other animals. They may be
divided into two classes,—those which live on the
surface of the skin, and those which live in the skin. In the first class may be mentioned fleas, lice, bugs, ticks, &c.; and in the second, the itch-insect or sar

In the first case may be meanated neas, nee, ougs, ticks, &c.; and in the second, the itch-insect or sarcoptes, the pimple-mite or Demodex folliculorm; together with other species of the Acardae.

EPOCH, e'-pok (Lat. epocha, point of time).—In Astron., the longitude or right ascension of a planet, at any particular moment of time, is simply called the epoch of that planet, for the sake of brevity. In order to determine the future position of a planet in the heavens at any particular period, it is necessary to reck on from its epoch, or known longitude at a certain point of past time. In Chron., the term epoch is used synonymously with era, and signifies a certain time from which we begin to count a series of years. (See Exa.)

EPROUVETTS, ai-proo-set (Fr.), in Mil., the name given to a contrivance by which the strength of gunpowder is ascertained. There are two methods of doing this; the first being effected by what is called the gun eprouvette, and the second by the mortar eprouvette. The latter is by no means an accurate test for comparing the strength of different kinds

London :-

## Epsom Salts

of powder, unless the grain of all the sorts to be tried be of the same size. A small charge is put into a mortar, and a suitable spherical iron shot is placed upon it. The charge is then exploded, and the distance to which the projectile is thrown is carefully measured. The range obtained is, of course, greater or less according to the strength of the powder. In the gun eprovette, a gun is attached to an iron rod at its centre of gravity, or point at which the gun would exactly balance if placed across a horizontal bar. The upper part of the rod is fastened to a horizontal bar. upper part of the rod is fastened to a horizontal bar, the ends of which rest in sockets, and which forms an axis, about which the whole apparatus may swing backwards and forwards when set in motion. From the lower part of the gun, and in a continuous vertical line with the bar by which it is suspended, a rod of line with the bar by which it is suspended, a rod of iron projects, the point of which works in a groove cut in a piece of wood fixed below it, in the form of the arc of a circle, whose centre is in the axis, about which the whole machine oscillates. This groove is filled with a soft substance. The gun is loaded with a carefully-measured charge of powder, and when fired, the recoil of the gun causes the point of the rod projecting from the under part to describe a line on the soft substance in the groove, the measurement of which determines the strength of the powder. Sometimes a brass quadrant is fixed to the unper part of the times a brass quadrant is fixed to the upper part of the rod by which the gun is suspended, on extent of the recoil is marked by an index. on which the

Erson Salts, ep'-sum, in Chem., sulphate of magnesia is known in commerce as Epsom salts, a name derived from the circumstance of its being largely contained in the springs in the neighbourhood of Epsom.

EQUATION, e-kwai'-shun (Lat. æqnare, to make even or equal).—In Astron., the rate of motion of the heavenly bodies revolving in elliptic orbits is variable, and they are, from different causes, sometimes in advance of and sometimes behind, the position in which they would be if they travelled at a uniform rate of motion. In be if they travelled at a uniform rate of motion. In calculating the position of a heavenly body from any epoch, a small amount, by way of correction, must consequently be added to or taken from its longitude at the time required, as it would be if it moved at a uniform rate; and this correction, in Astron., is termed an equation. There are various equations required in astronomical calculations of the longitude of heavenly bodies at circun periods arising from the required in astronomical calculations or the longitude of heavenly bodies at given periods, arising from the attraction exercised on the planets by the sun, and that which they exercise on one another and their satellites. The moon's annual equation, the equation of time, and the equation or precession of the equinoxes, will be noticed elsewhere. (See Sun, Moon, PRECESSION.)

EQUATION, ANNUAL.—The action of the sun upon the moon, by its mean influence, during many succes-sive revolutions of both bodies, tends to increase permanently the moon's distance and periodic time. This general average is not established without a series of subordinate fluctuations. In the lunar theory some of these are very sensible to observation. The most conspicuous is that termed the moon's annual equation. It is so called because it consists in an alternate increase and decrease in her longitude, corresponding with the earth's situation in its annual orbit,—namely, to its angular distance from the perihelion; and there-fore having a year instead of a month, or aliquot part of a month, for its period.

EQUATIONS, a term appled in Algebra to those propositions which assert the equality of two quantities. The sign = placed between the two quantities signifies that they are equal. Thus 5x + 10 = 25, is an equation expressing the equality of the quantities 5x + 10 and 25. A simple equation is that which contains only the first poper of the unknown quantity or quantities. Pure equations of the higher degrees are those which Pure equations of the higher degrees are those which contain the square or any higher power of the unknown quantity, and are divided into two classes.—pure and affected. A pure equation is that in which only one power of the unknown quantity is involved, and an affected equation is that in which different powers of the unknown quantity are involved. Thus,  $as^2 = b$  is a pure equation, and  $as^2 + bs = c$  is an affected equation. An affected quadratic equation is that which contains the square of the unknown quantity and also the unknown quantity itself. the unknown quantity itself.

## Hauida

EQUATOR, e-kwai'-tor (Lat. aques, equal), in Astron. and Geog., the name given to the imaginary great circles that surround the heavens and the earth midcircles that surround the neavens and the earth mig-way between the poles, so that every point in them is equidistant from each polar point. The plane of the terrestrial and celestial equator is at right angles to the axis of either sphere. The equator is so called because day and night are equal when the sun crosses it at the vernal and autumnal equinoxes in his passage

along the ecliptic.

EQUATORIAL INSTRUMENT, e-kud-to'-re-al, an astronomical instrument of exceedingly complicated con-struction, fitted with a declination-circle, an hour-circle, and a telescope for taking observations, su-pended in such a manner that it may be directed at pleasure to any point in the heavens that it may be desired to inspect. The whole instrument can be moved on two axes,—one of which is called the polar axis, as it is in the direction of the poles of the heavens; and the other, the transit or declination axis, which carries the odeclination circle, and is placed at right angles to the polar axis. The best equatorial instrument for general purposes is one called the Portable Universal Equatorial, made by Troughton. It is fixed on a stand, which can be brought to a proper level by means of screws and spirit-levels attached to its base. At the screws and appartneyers accanned to its rease. Account top of the stand, a horizontal axis is placed, moving in sockets in the ends of the uprights that rise perpendicularly from its base. The polar axis is fixed to the cross axis, and at right angles to it. This may be set in its proper position by a latitude-circle attached to the cross axis and moving in a plane parallel to to the cross axis, and moving in a plane parallel to that in which the polar axis moves. A tube, or inner axis, revolves within the tube which forms the polar axis, having an hour-circle attached to its lower ex-tremity, which is regulated by a tangent-screw placed at the opposite end. The rest of the instrument is attached to a plate fixed to the top of this inner tube, and revolving with it. Upright pieces rise from either end of the plate, with sockets to carry the transit-axis, at one extremity of which a declination-circle is fixed, at one extremity of which a declination-circle is fixed, and at the other a telescope. From the construction of the instrument, it will be seen that the plate fixed to the upper part of the inner tuhe of the polar axis, and the hour-circle at its other extremity, move in planes parallel to that of the equator when the polar axis has been properly adjusted. The method of using this instrument, and the principles or which it is made axill be better understood by

method of using this instrument, and the principles on which it is made, will be better understood by an inspection of the instrument itself, or a drawing of it on a large/scale.—Ref. Rees's Cyclopadia; English Cyclopadia,—Arts and Sciences.

EQUEREY, ch-we-re (Lat. equus, a horse; Fr. écuyer, a squire), an officer of state who holds office in her Majesty's household or in the household of princes of the royal family. An equerry is always in attendance on the Oneson on state occasions, and when she rides the royal family. An equerry is always in attendance on the Queen on state occasions, and when she rides or drives. The equerries are officers under the master of the horse, and the senior among them is designated this follower of the horse, and the senior among them is designated the following the designated the following the designation of the following th

tunales.

EQUESTRIANISM. (See HOBSEMANSHIP.)

RQUESTRIAN STATURS. (See STATURS.)
EQUID.M., e-kwi'-de, an order established for the reception of the horse and its allies. Their most striking character consists in the structure of the feet, which character consists in the structure of the feet, which are composed of but a single finger or toe terminating each extremity, and encased in a horny sheath or shoe, Besides this well-developed toe, however, the Equido possess on each side of the metacarpus said metatrasus two small rudimentary processes, which represent two lateral toes. The structure of the leg bores is much the same as in the generality of mammalia, except that the humerus and femur are comparatively short, and the bones of the forearm and shank, which are much longer, are partially ankylosed together, so that no

#### Equilateral

rotatory motion of these bones can take place. bones of the carpus and tarsus are large and solid, and nones of the carpus and taraus are large and solid, and resemble the bones of the other mammalis in their general arrangement. Beyond these we find a single elongated metatarsal bone, the representative of the middle toe. This is completed by three plaslanges, of which the last bears the single horny hoof. Dr. Gray thus defines the family of the Equide: —"This family (which is distinguished from all other animals by its undivided hoof formed of the two anterior trees sol-(which is distinguished from all other animals by its undivided hoof, formed of the two auterior toes sol-dered together, its simple stomach and its female having the tests placed on the pubes) may be divided into two very distinct types of form,—the one the asses and the zebras, which are always more or less banded with blackish brown, and have always a distinct dorsal line, the tail only bristly at the end, and have warts only on the arms, and none on the hind legs; and the true horses, which are not banded, have no dorsal line, are furnished with warts on their arms no dorsal line, are furnished with warts on their arms and legs, and have long hair on the tail from its insertion to its extremity." The skull of the Equidæ is of an elongated form, the jaws being well developed, the lower one especially being of great strength and power. Both jaws are provided with six incisor teeth; small canines are also present in both jaws in the males, but in the females these teeth are usually rudi-

of the neck and on the tail. The eye is rather large and full, and the external ears elongated, upright, and pointed. The most important species belonging to this family is, without doubt, the horse (Equus caballus). (See HORSE.)

EQUILATERAL, e-kwe-läte-e-rät (Lat. æquus, equal; lateralis, side), having all the sides equal; as an equilateral triangle. All the regular polygons are equilateral.

mentary or quite deficient. The molars are six or each side in each jaw; their worn surface is flat, and exhibits a complicated pattern of enamel, generally of

a lunate form. Between the molars and neisors there is a considerable space, and in this space is fitted the bit by which the animal is guided. The hair with which the skin is clothed is short on the general surface, but attaining a considerable length on the ridge of the neck and on the tail. The eye is rather large

lateral. EQUILIBRIUM, e-kwe-lib'-re-um (Lat. aquus, equal; libra, balance), in Statics, is a state of rest produced by the mutual counteraction of several forces. Two equal forces, acting in contrary direction, for example, destroy one another, and produce equilibrium; as when the two ends of a lever or balance, charged with equal weights, maintain a level position. (See MECHANICS,

ETATICS.)
EQUILIBRIUM OF ARCHES.—This is a subject which is treated in that part of mathematical science called Statics. In this the conditions are considered in which any body, or number of bodies, will remain in a state of rest under the influence of forces that act in opposite directions, and mutually counteract each other. It is evident that the conditions of equilibrium can be considered in theory only, as the slightest possible addition to either of the counteracting forces would addition to either of the counterating forces would immediately give it a preponderating influence, and destroy the state of balance. In investigating the equilibrium of arches, we must imagine the surfaces of the voussoirs to be perfectly smooth, and friction must be altogether disregarded, so that each stone may be considered to be sustained by the pressure of those on either side of it exting under these conditions in di considered to be sustained by the presence of those on either side of it, acting, under these conditions, in di-rections perpendicular to their surfaces. The theory on which the equilibrium of arches depends is briefly this, that the weights of the voussoirs of which it is comrough that the weights of the same proportion to each other as the sections of the chord of the arch, which are made by producing the lines which represent the junctures of the sides of the voussoirs to the centre from which the line sides of the voussoirs to the centre from which the line of intrados is described, supposing the arch to be a segmental arch. It is also necessary that the perpendicular passing through the centre of gravity of any part of the arch should pass through a parallelogram formed by lines drawn perpendicular to the sides of the part in question from their extremities. In such an arch the voussoirs at the crown would be the least in depth, and each successive voussoir, from the crown towards the piers, would increase in thickness, so that the line of the extrados would not be described from the same centre as that from which the line of intrados

## Equisetaceæ

has been described. The slightest alteration of the weight of any of the voussoirs of such ar arch as this, in which the stones that compose it are supposed to be supported without friction, would cause it to be over-turned; but when friction is taken into account, it is plain that an arch, which would remain in equilibrium under the conditions above stated, if they could exist in practice, would then be capable of sustaining a great amount of superincumbent pressure; and, indeed, pressure on the arch tends to make it stronger, by increasing the friction by which the pressure on it is resisted. The theory of the equilibrium of domes is somewhat similar to that of the equilibrium of arches, if we consider the dome to consist of a series of exactly equal and opposite slices, that are formed by planes passing perpendicularly through the axis at a small angle to each other, and which support each other at the crown, being, in fact, a number of balanced arches, the crown, being, in fact, a number of balanced arches, each of which would preserve its equilibrium, if it were left standing alone. But in the dome equilibrium will be maintained, and the structure will be stronger, if the weight of the upper part of each of such a series of contiguous balanced arches be greater than that which would be required to preserve equilibrium in a balanced arch of similar form standing alone; because every stone in each circular and horizontal course, or each of the whole series of the opposite parts of the balanced the whole series of the opposite parts of the balanced arches, exerts a lateral pressure on those on either side of it, and their tendency to fall inwards locks the whole structure tightly together. To insure the equilibrium of an arch, friction being disregarded, it is therefore necessary to bring the weight of the voussoirs composing the crown up to a certain limit, which must not be increased or diminished in any way; but in the dome, equilibrium will be maintained, for the reasons above extend when the weight of the unparaportion of above stated, when the weight of the upper portion of each of the series of arches of which it may be supposed to be composed exceeds this limit.—Ref. Robison's Mechanical Philosophy; English Cyclopædia,—Arts and

EQUINOCTIAL, e-kwe-nok'-shal (Lat. æquus, equal nox, night).—The celestial equator is sometimes called by this name, because day and night are of equal length all over the world when the sun crosses the equator.

EQUINOXES, ek-we-noks-ex, the points in which the great circles known as the ecliptic and equator cut each other. They are distinguished as the vernal and autunnal equinox. The sun is at the former on the 21st of March, when he enters the first point of Aries; and at the latter on the 22nd of September, when he enters the first point of Librs. In the southern hemisphere, the names of the equinoxes are transposed; the vernal equinox to those who are north of the equator becoming the autumnal equinox to those in countries lying to the south of it; and the autumnal, the vernal equipox.

EQUIFAGE, ek-we-paij (Fr. équiper), a term applied in general language to the carriage, horses, and liveries of a gentleman when abroad. The word is also applied of a gentleman when abroad. The word is also applied to the furniture of an army or body of troops. In this sense it includes arms, artillery, utensils, provisions, &c. Camp equipage includes tents and things necessary for accommodation in camp; while field equipage consists of arms, artillery, waggons, tumbrils, &c. In marine affairs, the word equipage is applied to the crew of a ship, together with all her furniture, masts, sails, ammunition, and general stores.

RQUIERTACHER, et-we-re-tail-se-c (Lat. equus, a horse; seta, a hair, or bristle), in Bot., the Horsetail fam., a nat. ord. of Acotyledones, sub-class Acrosens; con-

nat. ord. of Acotyledones, sub-class Acrogenæ; consisting of herbaceous plants, with striated, hollow, jointed, simple or verticillately-branched, acrial, silicious stems, arising from slender creeping rhizomes, or underground stems. The joints are surrounded by membranous toothed sheaths, which are regarded as modified leaves; but, in general, the plants of the order are considered leafless. When branched, the branches arise in a whorled manner from beneath the axis of the test of the content of the the teeth of the sheaths, and correspond in number with them. These plants are found in marshy or watery places in most parts of the world. There is but one genus, Equisetum, which includes about ten species, the greater number of which are indigenous. The rhizomes contain much starchy matter in the winter

months, which might be used as food in case of need. The silex, or flint, contained in the tissue of the rough horsetail, Equisetum hyemale, renders it a useful plant. Its stems are largely imported from Holland under the name of Dutch rushes, and employed by cabinet-makers, whitesmiths, and ivory-turners for smoothing

the surface of their work.

EQUISETITES, ek-we-se-ti'-tes (Lat. equisetum, the plant horsetail, in Geol., the name given to fossil plants which resemble the equisetum of our pools and marshes. They are found in all formations, from the Devonian upwards, and have jointed stems, surrounded by closely-fitting cylindrical sheaths, which are regularly toothed, and which leave their impress on the stems. They may be distinguished from the Calamites, for which they are apt to be mistaken, by their stems not being channelled throughout.

Being channeled introduct.

EQUIESTME. (See EQUIESTACE E.)

EQUIES, sk'-me-teez (Lat. plur. of eques, a knight, a horseman).—The equites, or knights, were a large and important body in ancient Rome, originally founded by Romulus, who divided his people into three tribes, and selected a hundred from each to serve on horseback as selected a nuncred from each to serve on noiseasce by his body-guard. Their numbers were increased by succeeding kings, and at last they became an order in the state, known as the equestrian order, in which any one could be enrolled who was possessed of the requi-site amount of property. They ranked next to the site amount of property. They ranked next to the senators, and occupied seats in public places of amusement that were especially set apart for them. They were distinguished by wearing a gold ring, and a border on their vestments a little narrower than that worn by the senators. They always formed the chief part of the Roman cavalry, if not the entire body, and were commanded by an officer of high rank, who was styled magister equitum, or master of the horse. Some idea may be formed of the number of the equites from the story told by Roman historians, that Hannibal sent to Carthage three bushels or measures (tres modies) of gold rings taken from the fingers of the knights that lay dead on the field after the battle of Canne, fought Aug. 2, 21t B.C., in which 40,000 Romans

EQUITY. ek-we-te (Lat. æquitas), in a moral and eneral sense, is that which, in human transactions, is general sense, is that which, in animal standard from the founded in natural justice, in bonesty and right, -sr equo et bono. "Equity, in its true and general meaning," says Biackstone, "is the soul and spirit of all law; positive law is constructed, and rational law is made by it. tive law is constructed, and rational law is made by it. In this, equity is synonymous with justice; in that, to the true and sound interpretation of the rule." It is applied to cases to which the law, on account of its generality, does not exactly apply, but which must be determined by the sound judgment of the proper interpreter. In this sense, equity must have a place in every rational system of jurisprudence, if not in name, at least in substance; for it is impossible that any code, however minute and particular, should embrace, or provide for, the infinite variety of human brace, or provide for, the infinite variety of human affairs, or should furnish rules applicable to all of them. Cases will occur to which the antecedent them. Cases will occur to which the antecedent rules will not apply without injustice, or to which they cannot be applied at all; and it is the office of a judge to consider whether the antecedent rule does, or ought, to apply to a given case. Hence arise a variety of rules in the interpretation of laws, according to their nature and operation, whether they are remedial or penal, or restrictive of general right, or in advancement of public justice. In the law of England, however, equity has a different and more restricted meaning. Remedies for the redress of wrongs, or for the enforcement of rights, are distinguished into two classes,—those which are administered in courts of equity. The rights secured by the former are called legal: those by the latter, equitable. The former are rights and remedies at common law; the latter, rights and remedies in equity. Much missunderstanding has prevailed regarding the distinctive features of these two branches of jurisprudeance. Some have represented them as two opposing and hostile powers, continually their nature and operation, whether they are remedial two pranches of jurisprudence. some have represented them as two opposing and hostile powers, continually at warfare with each other, and striving to encroach on each other's province, as if, in the language of Blackstone, "the one judged without equity, and the other was not bound by any law." It has also been 786

stated that a court of equity is not bound by rules or precedents, but acts from the opinion of the judge; and that the province of equity, as distinguished from law, is to determine according to the spirit of the rule, and not according to the strictness of the letter. In the early history of equity jurisprudence, there might have been much to give colour to these views; but in have been much to give colour to these views; but in the present day, courts of equity act upon principles as fixed and certain as those on which courts of law proceed. New cases may, and indeed do, arise; but they are decided upon these ascertained rules and principles, whatever may be the opinion of the judge as to what may be just or reasonable in the particular case before him. Equity, then, is a branchof jurispru-dence which aims at anynementing the defects of condence which aims at supplementing the defects of common law, by extending relief to those rights of property which the strict law does not recognize, and by giving more ample and distributive redress than the ordinary tribunals afford. It by no means either contrels, mitigates, or supersedes the common law, and does not assume any power to subvert its doctrines. Courts of common law proceed by certain prescribed forms, and give a general judgment for or against the defendant; but there are many cases in which a simple judgment for either party, without qualifications and conditions and particular arrangements, would not doentire justice to either. Some modification of the rights of parties may be required, some restraints on the one side or the other, or some peculiar adjustments, either present or future, temporary or perpetual. To meet these objects, the courts of law in this country have no provisions; they can only adjudicate by a simple judgment between the parties. Courts of equity, however, are not confined or limited in their modes of relief by such narrow regulations, but grant redress to all parties where they have rights. dence which aims at supplementing the defects of combut grant redress to all parties where they have rights, ex ague et bono, and modify and fashion that redress according to circumstances. Cours of equity, too, bring before them all the parties interested in the subject-matter of the suit, and adjust the rights of all, subject-matter of the sut, and adjust the rights of all, however numerous; whereas courts of law must limit their inquiries to the contending parties. The most general description of a court of equity, as given by Mr. Justice Story, in the "Encyclopedia Americana," is "that it has jurisdiction in cases where a plain, adequate, and complete remedy cannot be had at law; that is, in the common-law courts. The remedy must be plain; for if it be doubtful and obscure at law, equity will assert a jurisdiction. So it must be adequate at law; for if it fall short of what the party is entitled to, that founds a jurisdiction in equity. And it must be complete; that is, it must attain its full end It must be complete; then is, it must each it is must each the whole mischief, and secure the whole right of the party, now and for the future; otherwise equity will interpose and give relief." The jurisdiction of a court of equity is sometimes concurrent with that of common law, and sometimes it is It exercises concurrent jurisdiction in cases where the rights are purely of a legal nature, but where other and more efficient aid is required than a court of law can afford, to meet the difficulties of the court of law can afford, to meet the difficulties of the case and insure full redress. In some of these cases, courts of law formerly refused all redress, but will now grant it. The jurisdiction, however, having been once justly acquired by the courts of equity, at a time when there was no such redress at law, it is not now relinquished. The most common exercise of concurrent jurisdiction is in cases of accident, account, dower, fraud, mistake, partnership, and partition. The remedy here is often more complete and effectual than it can be at law, and in many cases falling under these heads be at law; and in many cases falling under these heads, and especially in some cases of fraud, mistake, and accident, courts of law cannot, and do not, afford any accident, courts of law cannot, and do not, afford any redress; in others they do, but not always in so full and perfect a manner. A court of equity is also assistant to the jurisdiction of courts of law in many cases where the latter have no like authority. It will remove legal impediments to the fair decision of a question depending at law. It will prevent a party from improperly setting up at a trial some title or claim which would be inequitable. It will compel him to discover, on his own oath, facts which he knows are material to the right of the other party, but which a court of law cannot compel him to discover. It will perpetuate the testimony of witnesses to rights and titles which are

## Equity

in danger of being lost before the matter can be tried It will provide for the safety of property in dispute, pending litigation. It will counteract and control, or set aside, fraudulent judgments, by restraining the parties from insisting upon them. A court of equity exercises exclusive jurisdiction in all cases of merely equitable rights; that is, such rights as are not recognized in courts of law. Most cases of trust and confidence fall under this head. Its exclusive jurisdiction is dence tall tinder this head. Its sections by little denoted has extensively exercised in granting special relief beyond the reach of the common law. It will grant injunctions to prevent waste or irreparable injury, to secure a settled right, to prevent vexatious litigations, or to compel the restitution of title-deeds. It will appoint compet the restriction of title-deces. It will appoint receivers of property where it is in danger of misapplication; will compel the surrender of securities improperly obtained; prohibit a party from leaving the country in order to avoid a suit; will restrain any undue exercise of a legal right against conscience and equity, and deerce a specific performance of contracts respecting real estates. It will in many cases supply the imperfect execution of instruments, and reform or alter them according to the real intention of the par-ties; will grant relief in cases of lost deeds or securities; and, in all cases in which its interference is asked, its general rule is, that he who asks equity must do equity. Whether it would be best to administer do equity. Whether it would be best to administer the whole of remedial justice in one court or class of courts, without any separation or distinction of suits, or of the forms or modes of proceeding, is a question upon which much difference of opinion exists. Lord Bacon has given it as his decided opinion, that the separation of common law and equity was wise and convenient. "All nations," he says, "have equity; but some have law and equity mixed in the same court, ont some nave law and equity mixed in the same court, which is worse; and some have it distinguished in several courts, which is better." Lord Hardwicke was of the same opinion; and, indeed, it is the general opinion in those countries, as England and the United States of America, where the two exist separately. "There is nothing," says Mr. Justice Story, "incongruous, much less abourd, in separating different portions of municipal jurisprudence from each other in the administration of justice, or in denving to one court the administration of justice, or in denying to one court the power to dispose of all the merits of a case when its forms of proceeding are ill adapted to afford com-plete relief, and giving jurisdiction of the same cause to another court better adapted to do entire justice by its larger and more expansive authority." It is most to another court better anapted to definite justice by its larger and more expansive authority." It is most probable that its suitability depends upon the habits, circumstances, and institutions of each particular na-tion, and that while it might be well adapted for one country or one age, it might be unsuitable for another. A suit is usually commenced in the courts of equity or A suit is usually commonced in the courts of equity or chancery by presenting a petition to the lord chancellor, containing a statement of the plaintiff's case, and praying for redress. Frequently allegations are made in a bill, of which the plaintiff is uncertain, or which are merely conjectural, in order to elicit from the defendant a full discovery of the truth. Formerly, a writ of subpona was issued, commanding the defendant to appear and answer the allegations of the bill within a certain time; but now, in place of the subpona, a printed bill is served, which has the same effect as the service of a writ of subpena. If upon the face of the bill sny cause be apparent why the redress should not be granted, the defendant may demur, or out in a demurrer; and if such cause exist, and yet not apparent upon the bill, he may put in a pleas stating such matter, and demanding judgment of the court, as in a demurrer. In either case, the subject is at once taken up and argued before the court, and, if allowed, the suit, or so much of it as is affected by the plea or demurrer, falls to the ground; but usually, on cause shown, the court will allow the plaintiff to amend his bill. If the defendant can neither demur nor put in a plea, and cannot disclaim, then he must answer, upon s writ of subposua was issued, commanding the debill. If the detendant can necessary and cannot disclaim, then he must answer, upon oath, the interrogatories in the bill, according to the heat of his knowledge and belief. If the answer is oath, the interrogatories in the bill, according to the best of his knowledge and belief. If the answer is sufficient, and the bill does not require amendment, issue is joined in the cause, witnesses are examined, the cridence is closed, and the cause set down for hearing, and heard in its term. In some cases, the decree made on the hearing decides all the questions in the cause; in other cases, preliminary accounts, 787

## Erastianism

inquiries, and directions, are adjourned to chambers; and when these are answered, the cause comes on for hearing on further cousideration, and the points in issue are disposed of. The court decides upon the proofs, arguments, and merits brought before it without the assistance of a jury; yet, if a serious doubt be entertained as to a question in fact, the court may direct an issue upon it to be tried by a judge and jury to at common law, and may now itself impants a jury to at common law, and may now itself impanel a jury to award damages to an injured party, either in addition to, or in substitution for, an injunction or specific performance, pursuant to 21 & 22 Vict. c. 27. This judges of the equity courts are the lord chancellor, the master of the Rolls, the two lords justices of the Court of Appeal in Chancery, and the three vice-chancellors. The ordinary business is transacted by the master of the Rolls and the three vice-chancellors.

EQUIVALENTS. (See ATOMIC NUMBERS.)
EQUULEUS, e-kyu-ul'-e-us (Lat., the little horse),
one of the old Greek constellations made by Ptolemy, and situated between Aquila and Capricornus. Its brightest stars are of the fourth magnitude only. There is another constellation, named by Lacaille Equaleus pictoris, the easel, or painter's horse, which is situated near the constellation Argo.

Eza, e'-ra (Lat. zra), the name given to a point of time that is marked by some remarkable occurrence, and from which it has been consequently determined to and from which it has been consequently determined to count the series of succeeding years. Various eras have been chosen by different nations, but fixed, indeed, in an arbitrary manner, from which they have reckoned the principal events occurring in their history in chronological order. The most important of these is the Christian era, which was invented by a monk, Dionysius Exignus, in the year 532 A.D. The first year of this era was supposed to be the year in which our Saviour was born; but this supposition has been found to be incorrect, as the birth of Christ is now allowed to have taken place four years previously. From this era the majority of the Christian nations of the world reckon events both backwards and forwards; any event which happened before this date being any event which happened before this date being spoken of as taking place in the year — before Christ, spoken of as taking place in the year spoken of astaking place in the year — before Christ, or B.C., and any which has happened since, as occurring in the year — of our Lord, or A.D. In the system of chronology generally adopted, the date of the creation of the world is fixed at 4004 B.C.; but the creation of the world is fixed at 4004 B.C.; Dut this is uncertain, and many different dates have then assigned to this event: thus, according to the Septuagint, it took place in the year 5872 B.C.; according to the Julian period, 4710 B.C.; and ac-cording to the mode of reckoning used by the Jews, 376 B.C. The other principal eras from which events have been reckoned by the Greeks, Romans, Window and Makemeters, are as follows.—The events have been regioned by the Greeks, klomans, Hindoos, and Mahometans, are as follows:—The Greeks reckoned by Olympiads, or periods of four years each, the first year of the first Olympiad coinciding with the year 776 B.C. The Romans reckoned from the building of the city Rome, which took place 753 B.C., in the fourth year of the sixth Olympiad. The principal Hindoo eras are those of the Cali Yuga and Vieramaditya, which correspond with the years 3103 and 56 B.C. The Mohameddan era, called the Hegira, dates from the flight of Mahomet from Mecca, which took place 622 A.D. The rules by which the year of the Christian era may be found that corresponds with a given year of any other particular era, and vice versa, will be found in the notice given of each important era under its own heading. (See Cali Yuga, Hegira, Olympian, Varronian Fra, &c.)

Errstianism, e-rās'-le-ān-izm, a religious theory, first propounded by Erastus, a German divine of the 16th century. His proper name was Liebler, or Lieber, which, according to the fashion of the day, be changed to the Greek equivalent Erastus, 'beloved.'

According to his theory, the pastoral office was only recremanic like that of a workeage of sciences over his Hindoos, and Mahometans, are as follows :- The

changed to the Greek equivalent Erastus, 'beloved,' According to his theory, the pastoral office was only persuasive, like that of a professor of sciences over his pupils, without any power annexed. The Lord's Supper, like other ordinances of the Gospel, was, he declared, to be free and open to all; the minister might dissuade any one from joining, but might not refuse. Erastianism referred the punishment of all offences to the civil magistrate. The theory was for a time prominent in England, and Selden, Lightfoot, Coleman, and Whitelocke, pelonged to the Erastian party.

#### Erbium

Errum, er'-be-um, in Chem., an exceedingly rare metal, found with yttrium and terbium in gadolinite. The oxide erbie is similar in its characteristics to alumina. It has a dark yellow colour, but forms

ERECETHEUM, or ERECETERIUM, e-rek-the'-um, one of the most important temples of ancient Athens, which stood on the north side of the summit of the Acropolis. The temple that originally occupied the site was built by Ercottheus, who reigned over Attica in the latter part of the latth century B.O. It was designed for the reception of the image of Minerva, carved out of the trunk of an olive-tree, which was always a special object of veneration to the Athenians. Ercettheus was buried in the temple; from which circumstance the name of Erechtheum was afterwards given to that which was built on the same site about 400-395 B.C., which was built on the same site about 430—395 n.c., the ruins of which may still be seen. The entire building forms a group of three temples,—the Erechtheum properly so called, the temple of Minerva Polias, and the Pandrosium. The Erechtheum occupied the largest space, and is supposed to have been built first of all. It is in the form of a parallologram, about 73 feet iong and 37 feet wide. The portice before the prothyrium looks towards the east, and was very shallow, if a wall existed between this and the prothyrium, as supposed by Stuart. The entablature and pediment of the portice was supported on six massive but elegant Ionic columns, enproted on six massive but elegant Ionic columns, en ported on six massive but elegant Ionic columns, enriched with carving, and about 27½ feet in height. The temple of Minerva Polias was attached to the north side of the Erechtheum, at the western end, and stood on a lower level. It was nothing more than an open on a lower level. It was nothing more than an open portice, 33 feet wide and 21 feet in depth, the roof being supported by six columns, four in front and one on either side, 25 feet in height. It looked towards the north, and was probably nothing more than a side portice added to the Erechtheum at some time subsequent to its erection. The Pandrosium was attached to the western end of the south wall, and was tached to the western end of the south wan, and was built at a much later date than the other parts of the building. The roof of the portico, which has a southern aspect, was supported by six caryatides. (See CARYATIDES, ELGIM MARBLES.) The interior of the Pandrosium, or cella of the temple, was formed out rangesium, or cour of the temple, was formed out of the lower or western end of the Erechtheum, a portion about twelve feet in width being separated from it for that purpose by a party wall. The portice of the Pandrosium is about 18 feet wide and 12 feet deep.

—Ref. Fergusson's Handbook of Architecture; Stuart's

Athens; Inwood's Erechtheion.

EREMOCAUSIS, e-re-mo-kaw'-zis (Gr. erema, slow; kausis, burning), in Chem., a term applied by Liebig to the slow decay of moist organic bodies by the absorption of oxygen without the production of heat. The slow decay of wood, under the combined influence

of air and moisture, is an instance of this action.

ERGOT OF HYB. (See SECALE.)

ERICACEM, 8-ri-kai-se-s (Lat. erica, heath), in Bot. ENICACE. R. e-ri-kai'-se-e (Lat. erica, heath), in Bot., the Heath fam., a nat. ord. of dicotyledonous plants in the aub-class Corollifore, consisting of 42 genera and about 850 species. They are very abundant at the Cape of Good Hope, and are more or less generally diffused throughout Europe, North and South America, and Asis. The following details give the general character of the order:—Shrubby plants. Leaves entire, opposite, or whorled, extipulate. Calyx 4—5-cleft, inferior, persistent. Corolla hypogynous, monopetalous, 4—5-cleft; setivation imbricated. Stamens hypogynous, as many, or twice as many, as the divisions of the corolla; anthera 2-celled, opening by a sions of the corolla; anthers 2-celled, opening by a pore, appendiculate. Ovary many-celled, with numerous ovules, surrounded by a disc or scales; style 1. Fruit capsular, rarely baccate; placenta axile. Seeds numerous, small, anatropous; embryo in the axis of fleshy albumen. By Lindley, the order has been numerous, small, anatropous; embryo in the axis of fleshy albumen. By Lindley, the order has been divided into two sub-orders, — Ericea, in which the fruit is loculicidal, or rarely septicidal, or berried, and the buds naked; \*\*Rhododendrea\*, in which the fruit is capsular, septicidal, and the buds soaly, resembling cones. Many of the \*\*Ericacea\*, particularly species of the genera Erica, \*\*Rhododendren\*, \*\*Kulmia,\*\* and \*\*Aralea\*, are largely cultivated in this country on account of the hearity of this \*\*Incorrect\*\*.

## Ermine

they are not confined to America, as the name would imply. Medicinally, the plants of this order are chiefly remarkable for astringent properties. Some, however, are narcotic, and a few even poisonous. The fruits of many are edible.

ERIDANUS, e-rid'-a-nus, a constellation formed and named by Aratus after the river Eridanus. It stretches along the heavens from Phoenix to Orion, in the shape of a winding river; it has one star of the first magni-tude, and many of the third and fourth.

ERIOCAULACER, er-e-o-kaw-lai'-se-e (Gr. crion, wool : kaulon, a stem), in Bot., the Eriocaulon, or Pipe-wort fam., a nat. ord. of monocotyledones, consisting of aquatic or marsh plants, with clustered linear leaves, usually grass-like, and minute uniserval flowers growing in dense heads. They are mostly natives of tropical America and the north of Australia. One species is found in Britain; namely, Eriocaulon septan-gulare, the pipe-wort. They have not been applied to any useful purpose.

EBIODENDEON, ere-o-den'-dron (Gr. erion, wool; dendron, a tree), in Bot., a gen. of the mat. ord. Sterculiaces. The most remarkable species is E. Samauma, a native of South America. Its trunk frequently overtops all the surrounding trees before it gives off a single branch. The hairy covering of the seeds of various species of this genus forms a kind of vegetable silk much used for stuffing cushions and

similar purposes.

Emiorhouth, ere-of-o-rum (Gr. erion, wool; phoreo, I bear), in Bot., a gen. of the nat. ord. Cyperacce, or Sedge fam., consisting of numerous species, commonly known as cotton-grasses, from their fruits being surrounded by cottony or downy hairs. These hairs are sometimes used for stuffing cushions. The leaves

are reputed to possess astringent properties.

Erming, evi-min (Fr. hermine), Mustela ermina,
Linn.—This little digitigrade animal is found generally
in temperate Europe, but is common only in the north.
It is not generally known that the ermine and the stoat It is not generally known that the ermine and the stoat are the same animal: the confusion arises from the change that takes place in the colour of the animal's fur at the different seasons. In the winter it is yellowish-white, the yellow hardly showing about the head, but gradually appearing more and more on the body, and increasing in intensity, so that some are of a pale yellow colour on their hind parts: then it is known as the ermine. About the end of March, however, the upper parts change to reddish-brown, of rather a dull tint, the lower parts continuing white: the tail remains black at the tip through all the changes. It is in the extreme northern regions that changes. It is in the extreme northern regions that changes. It is in the extreme normern regions that this change in the animal's colour takes place with greatest distinctness. With regard to the manner in which this change is brought about, naturalists are not unanimous. One of the highest authorities, however, Mr. Bell, expresses his belief that the winter change is effected not by the loss of the summer coat and the substitution of a new one, but by the actual change of colour in the existing fur; and he cites, in proof of this view of the subject, the case of the Hudson's Bay lemming, which, in Ross's first polar expedi-tion, was exposed in its summer coat on the deck to aton, was exposed in its summer coat on the coat means at the statute of 300 below zero, and the next morning the fur on the checks and a patch on each shoulder had become perfectly white; at the end of a week, the winter change was complete, with the exception of a dark band across the shoulders, and prolonged down to the middle of the back. Like many other species of this genus, the ermine has the faculty of ejecting a fluid of a strong musky odour. Its fur is in great request; at one time it was one of the insignia of royalty, and it is still worn by the judges. Comparatively few ermine skins are at the present time exported from Hudson's Bay; but even so lately as 1850, 187,000 skins were received in England from that and other places.

ERMINE, in Her., the name of one of the furs used for the lining of mantles, crowns, coronets, and caps of maintenance, as well as for the field and charges of and the bude naked; another bude soaly, resembling is capsular, septicidal, and the bude soaly, resembling armoral bearings. It represents the white skin of the cones. Many of the Ericacea, particularly species of the genera Erica, Rhododendron, Kalmia, and Aralea, is tipped with black, attached to it, as in ladies' mufts, are largely cultivated in this country on account of the beauty of their flowers. The three latter genera spots and stripes, or tails, on a white field, each stripe are commonly called American plants by florists; but having two lines, or hairs, diverging from it, one on

#### Erosion

either side, and being surmounted by three spots, one placed at the extremity, and the others just below it, on each side of the point. There are four varieties of on each side of the point. There are four visited and stripes on a black field; Erminois, black spots and stripes on a gold ground; Pean, gold spots and stripes on a black ground; and Erminies, like ermine, but having a red hair diverging from either side of the string intend of a black one stripe, instead of a black one.

EROSION, e-ro'-thun (Lat. erosus, gnawed or worn away), the act of gradually wearing away; the state of being gradually worn away. In Geol., this term is employed to distinguish those features which are the results of the slow destructive action of running water, glaciers, the waves, and other agents; thus, valleys of crosion are those valleys which have been gradually cut out of the solid strata. Most of the ravines and glens and river-channels in the British isles are the results of erosion; for whatever inequalities of surface may have originally directed the waters into their channels, all the subsequent deepening, scooping out, canancies, all the subsequent deepening, scooping out, and widening of the valleys, have been owing to the erosive force of running water, laden with sand, gravel, and other triturating débris. The destructive action of breakers is very remarkable. Along the eastern coasts of Scotland and England, as is proved by old records, land existed far outside the present shore; the sites even of important towns of the 12th or 15th century being now under the sea. Even still, in many places, whole acres are annually consumed, and the total known destruction of the last few centuries is to be measured sometimes by miles. All sea-cliffs, crags, and pinnacles of rock may, as a general rule, be regarded as evidences of the crosion and destruction of the formerly more widely extended land by the moving surface of the sea. Just as actual sea-cliffs are proofs of the erosive action now in operation, so in almost all cases, inland cliffs, orags, scars, and precipices, as well as valleys, ravines, gorges, and precipices, as well as valleys, ravines, gorges, and mountain-passes, are proofs of the erosive action of the sea in times when the land stood at a lower level the sea in times when the land stood at a lower level with respect to it. A still more wonderful example of crosion is frequently afforded in a low and gently undulating district, from which the very mountains themselves, that geologists can prove once covered it, have been removed. (See RIVEE, GLACIEE, ICEBERG.) Exorto Poetray, e-rot'-ik (from Gr. eros, love), a term applied, in Greek and Roman literature, to amatory poetry. It is particularly used to signify the works of a certain class of romance writers and the Milesian tales. Excits poetry belongs more especially to the

tales. Erotic poetry belongs more especially to the later periods of classic literature, and it abounds in sophistical subtleties and ornaments. The most distinguished writers of this kind of poetry were Achilles Tatius, Heliodorus, Anacreon, Sappho, Ovid, Tibullus, Propertius.—For a collection of these writers, see Scriptores erotici Graci, curá Mitscherlichii.

EBRATO-BLOCK GROUP, er-rdf-ik (Lat. erraticus, wandering), in Geol., a synonym of the boulder clay, from the large transported blocks of stone which occur in it. The blocks, or boulders, are sometimes briefly

designated erratics. (See BOULDERS, PLYISTOGENE.)
ERRATUM, er-rai'.tum (Lat.), a term applied to those errors which have been overlooked in the composition or impression of a work. A list of the errata is generally placed at the beginning or end of a book.

ERRHINES, er-rines (Gr. errinen, from en, in; rin, the nose), in Med., those medicines which are applied to the mucous membrane of the nostrils. The term sternutatories is restricted to those which cause speezing. Errhines may be applied in a dry, soft, liquid, or gaseous state; they may be emollient, astringent, or stimulant,—the first sheathing irritated surfaces; the second restraining inordinate secretion, the consequence of relaxation; and the third favouring the natural mucous discharge, on the return of the secreting

# Ervsipelas

writ of error (in Latin, de errore corrigendo) used formerly to be brought for the eemedy thereof. Now, however, by 15 & 16 Vict. o. 76, this writ is, in almost every case, dispensed with; and proceedings in error consist of a simple memorandum of error lodged with the officer of the court, accompanied, if the error be in fact, with an affildavit to that effect. Error may be either now part and for the many the effect of the court either upon matter of fact or upon matter of law; but it is generally upon the latter. Formerly, writs in error were resorted to on very trivial grounds (as mis-spellings and other clerical errors), and interfered greatly with the due administration of justice; but it is now provided, that no judgment shall be reversed on account of any imperfection, omission, or defect of form; and even in case of material mistake, it is declared lawful for the superior courts, or any judge thereof sitting at nisi prius, at all times to make such amendments as may be necessary for the purpose of deter-mining in the existing suit the real question in contro-A writ of error must be commenced and proseversy. A writ of error must be commenced and prosecuted with effect within six years after the judgment is signed, or after the right of the party aggreeved to bring error accrued. Error lies only for some mistake

bring error accrued. Error lies only for some mistake in the proceedings in a court of record; for to amend errors in a base court a writ of false judgment is the remedy.—Ref. Stephen's Commentaries.

Ease, ere (a corruption of Irish), is a name given by the lowland Scotch to the Gaelic, or language of the inhabitants of the Highlands, from their being supposed to have come over from Ireland. (See Gaelic.)

Exvir, er-num (Lat. eruo, I pull up by the roots), in Bot., the Tarc, a gen. of the nat. ord. Leguminosa, sub-ord. Papilionacea, consisting of herbe with weak and slender etems, small papilionaceous flowers, and pods containing from two to four seeds. The species are common fodder plants in many parts of the world. The seeds of the E. Lens are called lentile, and have been used as human food from the earliest ages. They are seldom eaten in England; but throughout the conare seldom eaten in England; but throughout the continent of Europe, and in many parts of Asia, they are largely consumed. The lentil is considerably smaller than an ordinary pea, and is of the shape of a double convex lens; in fact, the word lens is simply the Latin name for this description of pulse. Several varieties of the lentil are cultivated; that which is most esteemed in France is termed lentille à la reine; it is very small, and has a reddish colour. Lentils are very in France is termed leatille à la reine; it is very small, and has a reddish colour. Leutils are very nourishing, but somewhat indigestible. The seeds of E\*Breilia, the bitter vetch, are said to be poisonous. Envirence. Farsirelas, ere-sip'e-las (Gr., from eruo, I draw, and pelus, near or adjoining), in Med., is the name given to a peculiar kind of inflammation of the skin, and pelus alled the side of the skin, and pelus alled the side of the skin, and the skin the side of the skin and the skin the skind of the skin the s

given to a peculiar kind of inflammation of the skin, so called from its tendency to spread to adjoining parts. It is known also as St. Anthony's fire or ignis sucer, and in common language as the Rose. It most commonly attacks the head and face; but it also sometimes occurs on other parts of the body. The local inflammation is preceded and accompanied with fever, and there are also usually certain premonitory symptoms that precede the outbreak of the disease; the patient felselli,—shivery, feeble, languid, and often drowsy. After these symptoms have continued for some time, a red snot appears on some part of the body, accompanied red spot appears on some part of the body, accompanied with a burning heat and tingling. When attacking when a current nest and ungung. When attacking the fuce, it usually makes its appearance on the bridge of the nose, and rapidly extends itself to the cyclids, cheeks, and forehead. The redness is not intense, but rather of a pale rose-colour, and goes away temporarily on pressure, but returns immediately on its removal. and no pit remains after the pressure. By the second night, or morning of the third day, after the commencement of the fever, the face begins to swell, the eyes are completely closed, and the form of the features scarcely recognizable. On the fourth or fifth day vegicities day, resications appear on the inflamed surface, and break or subside on the fifth or sixth, when the redness surface to a healthy state. The aromatic errhines commonly applied are powdered herbs.—as mint, arender, and rosemary; also tobacco as snuff. Ammonia and its carbonates are much employed. Acrid regetables and poisons, and preparations of mercury, are applied in rare cases.

Enson, er eror (Fr. erreur, from Lat. erro, I err, or go astray), in Law, signifies something wrong in the pleadings, or process, &c., upon which a writ, called a 1889.

#### Erythema

ration rarely occurs, except occasionally in the eyelids or scalp. Sometimes the inflammation and swelling or scalp. Sometimes the inflammation and swelling extend to the neck and throat, and may produce suffocation. In very bad cases, delirium and come come on, and death ensues from effusion on the brain. No remission of the fever takes place on the appearance of the inflammation; but, on the contrary, it generally increases with the progress of the inflammation, and only ceases when it goes away. When the complaint is mild, the inflammation and fever generally cease gradually without any evident crisis. A mone frequent gradually without any evident crisis. Among frequent causes of this disease, are exposure to a cold and moist atmosphere, sudden changes of temperature, intemperature, and unwholesome articles of food. It is sometimes also induced by wounds or sores, or even a slight puncture or scratch of the skin in persons predisposed to it. It is likewise contagious, and has to be strictly guarded against by means of ventilation and cleanliness in hospitals. Though the proper seat of the inflammation is the skin, it frequently extends to the parts underneath. Authors usually distinguish four kinds of this disease,—the phlegmonous, cedematous, gangrenous, and erratic, The first of these is characterized by the greatest degree of inflammation. In the adematous, the inflammatory symptoms are less intense, but the tunefaction is greater. It most commonly affects persons faction is greater. It most commonly affects persons of debilitated constitution, dropsical persons, and those who have been long subject to other chronic maladies. It is attended with considerable danger when it affects the face, and often terminates fatally on the seventh or eighth day. The gangrenous form most commonly occurs in the face, neck, or shoulders, and is accompanied with symptoms of low fever and delirium, which is succeeded by coma. The colour of the affected partie of a darkred, and scattered vesicles appearance the artiface which fragmently terminate in conupon the surface, which frequently terminate in gan-grenous ulcerations. It is always a tedious, and often a fatal form of the disease. In erratic crysipelas, the a fatal form of the disease. In erratic crysipelas, the morbid patches appear one after the other in different parts of the body; sometimes thus travelling progressively from the head to the extremities. It is rarely attended with danger, and usually terminates in a week or ten days. In the treatment of crysipelas, very much depends upon the nature of the disease and the condition of the patient. If the patient be young and sanguine, and the inflammation high, bleeding may be had recourse to. When, on the other hand, the system is enfeebled, tonice, a nourishing diet, and even stimulants, may be necessary in order to and even stimulants, may be necessary in order to strengthen the patient. In general, moderate purga-tives, diaphoretics, and strict confinement to bed, are to be adopted. In order to allay the local irritation, it is recommended to wash the part from time to time with warm milk-and-water. [A solution of nitrate of silver has been employed in some cases with very beneficial results.

ENTIREMA, ere-the'-ma (Gr. eruthros, red), in Med., is a lesser kind of erysipelas, being characterized in like manner by some degree of redness of the skin and disorder of the constitution, but with little swelling, and little tendency to suppuration or vesication. It is not infectious. Medical writers distinguish six varieties of this disorder. It usually arises from some local irritation, or from a disordered state of the digestive organs. In the former case, it is to be remedied by the removal of the cause of irritation and the ablution of the part with warm water or some gentle stimulating lotion. In the latter case, the proper remedies for restoring the healthy condition of the digestive organs are to be employed.

ERYPHEMA, er-e-thre'-ā (Gr. eruthros, red), in Bot., a gen. of Gentianacea, consisting of herbaceous plants with erect branching stems, having opposite entire leaves, and pink, whitish, or yellow flowers. The most important species is E. Contaurium, the common centarry, an indigenous plant, having bitter tonic properties similar to these of gentiars.

taury, an indigenous plant, having otter tonic properties, similar to those of gentian.

ERTHEIMA, er-ith-ri-nā (Gr. eruthros, red), in Bot., the Coral-tree, a gen. of the nat. ord. Leguminose, sub-ord. Papilionaceæ; consisting of small trees, shrubs, and under-shrubs, natives of India, America, and the West Indies. Nearly all the species are remarkable for the brilliant scarlet colour of their flowers, owing to which they are much coldinated ag stove plants.

## Escape

ERYTHROPHLGUM, er-tith-rof'-le-um (Gr. eruthros, red; phioion, bark), in Bot., a gen. of the nat. ord. Leguminose, sub-ord. Mimosee. E. guineense is the sassy-tree of Western Africa, the bark of which, under the name of "ordeal bark," or "doom bark," is used by certain tribes as an ordeal to which persons suspected of witchcraft or secret poisoning are subjected, from the superstition that their innocence or guilt will be indicated by the effects produced by the bark on the system.

ERTHROXYLACES, or-e-throks-clai-see (from erg-throxylon, from Gr. eruthros, red, and xulon, wood), in Bot., the Erythroxylon fam., a nat. ord. of dicotyledonous plants, in the sub-class Thatamiflore; consisting of but one genus, Erythroxylon, which includes seventy-five species, natives of the warmer regions of the globe, and especially abundant in Brazil. This order is closely allied to Malpiphiacea, and in fact scarcely presents characters sufficient to warrant its separation from that order. Some of the plants are tonic, others purgative, and others stimulant and sedative. The wood of E. hypericifolium, and the bark of E. suberonum, are red, and are used for the preparation of dyes of that colour. Red is, in fact, the common colour of the wood throughout the genus; hence its name, which signifies red wood. The most important species is E. Coca, the leaves of which are much used by the Peruvians and other peoples of South America to form a masticatory, which is prepared by adding to them a very small quantity of an alkaline paste made from the ashes of different plants, or even a little common quick lime. The Indians of Peru have always ascribed to the coca marrellous virtues, believing that it will lessen the desire and necessity for ordinary food. Spruce says that an Indian with a chew of this masticatory in his cheek will go two or three days without food, and feel no desire to sleep. Dr. Weddell, however, speaks far less highly of the virtues of the coca; he states that it does not satisfy the appetite, but merely enables these who chew it to support abstinence for a length of time with a feeling of hunger or weakness. The use of coca is said to prevent the difficulty of respiration which is generally experienced in ascending long and steep mountains. Its excessive use is stated to be most injurious, producing analogous effects to those occasioned by the immoderate cousumption of opium and fermented liquors. Johnston has computed the annual consumption of coca at 30,000,000 lbs,, and has stated that its c

ENTREMANTION. (See ERYTHROXYLACEE.)
ESCALADE, es-kid-laid' (Fr., from Lat. scala, a ladder), a term applied, in military language, to a forious attack made by troops on a fortified place by means of ladders. In modern wariare escalades do not occur so frequently as in the olden time: they were then generally made at night, stealthily and in silence. Among the most celebrated modern escalades may be mentioned that made by the French troops at the sign of Prague, in 1741, and that of Antwerp, in 1832.

of Frague, in 1741, and that of Antwerp, in 1852. EscalLOMACES, es-khil-lo-ne-ai/se-e (in honour of Escallon, a Spanish traveller), in Bot., the Escallonia fam., a small nat. ord. of dicotyledones, sub-class Carlegifore, consisting of evergreen shrube, with afternate exstipulate leaves and axillary showy flowers. They are chiefly natives of the mountains of South America.

ESCALOP, or ESCALLOP, es-käll-lup (Du. schalp, a shell), a fam. of bivalve mollusks the shells of which are deeply indented. In the centre of the top of the shell is a trigonal sinus, with a hinge consisting of elastic cartilage. In Her., the escallop-shell is a frequent bearing in the escutcheon, it having been the pilgrims' ensign in their expeditions to the Holy Land.

pilgrims' ensign in their expeditions to the Holy Land.
ESCAR, es-kusy' (Fr. éshapper, to fly from), in
Law, is a violent or privy evasion out of some lawful
restraint; as where s man is arrested or imprisoned, and gets away before he is delivored by
due course of law. Officers who, after arrest, negligently permit a felon to escape, are punishable
by fine; but it is regarded as a much more serious

700

offence if the escape is effected by the consent and connivance of the officer, and is generally looked upon in law as punishable in the same degree as the offence of which the prisoner is guilty, and for which he is in custody, whether treason, felony, or trespass. outsuce or which the prisoner is guilty, and for which he is in custody, whether tresson, felony, or trespass. Breach of prison by the prisoner himself, when committed for any cause, was felony at the common law; but this serveity was afterwards mitigated, and now no person shall have judgment of life or member for the prison of the pri breaking prison, unless committed for some capital offence. But to break prison and escape when lawfully committed for any treason or felony, still remains felony, as at the common law, and is punishable with penal servitude for not more than seven or less than three years, or imprisonment not exceeding two years. To escape from confinement under sentence or order of penal servitude is punishable by penal servitude for life. To break prison when lawfully confined on some inferior charge is a high misdemeanor, and punishable by fine and imprisonment.

ESCAPRMENT. (See HOROLOGY.)

ESCARP, or SCARP, cs'-karp (Fr. escarper, to cut, strip), in Mil., that side of the ditch which forms the lower part of the rampart of a fortress, and which is below the natural level of the ground, or the summit of the glacis on the other side, is called the escarp or scarp. The slope of the escarp depends on the nature of the earth in which the ditch is cut, and the manner in which it is finished, varying from an angle of 45° with the level of the bottom of the ditch, if it consist of the soil only and loose rubble, to one of 80°, if the

of the soil only and loose rubble, to one of 80°, if the escarp be revetted with masonry.

ESCARPMENT, es-karp'-ment, a term applied to the steep and precipitous side of any cliff or hill, formed, in some cases, by the action of water, and in others by the abrupt termination of geological strata. The cliffs above the Giant's Causeway, and the promontory known as the Fair Head, Antrim, afford good examples of natural escarpments. The expression is also applied to rocks and hills that have been cut away by artificial means for military purposes, as in many parts of the rock of Gibraltar, which have been scarped

to render them inaccessible to an enemy.

ESCHALLOT, es-shall-lot' or shall-lot' (Fr. échalote),

Allium ascalonicum, a species of small onion or garlic.

Liss said to have come originally from Palestine.

ESCHAROTICS, es-kis-rof-siks (Gr. eschara), the crust of a scar produced by burning substances of a caustic nature which have the power of searing or destroying the flosh. The term is generally applied in Surg. to mild causting a 18se Clympur Carento.

mild causties. (See CAUTERY, CAUSTIC.)

ESCHEAT, es-tsheut' (Nor.-Fr. eschet or echet, chance or accident), in Law, is defined to be "an obstruction of the course of descent, and a consequent determination of the tenuro, by some unforeseen contingency, in which case the land naturally results back, by a kind Where the tenant of lands in fee dies without having aliened them in his lifetime, or disposed of them by will, and leaves no heir behind him to take them by will, and leaves no near remain and to execute of descent, they escheat to the grantor or lord of the fee. In order to complete this title by escheat, it is necessary that the lord perform an act of his own by entering on the lands and tenements so escheated; on failure of which, or by doing any act that amounts to an im-plied waiver of his right, as by accepting rent of a stranger who usurps the possession, his title by eschest is barred. The law of eschests is founded upon the principle that none can inherit a person's estate but such as are of his own blood and consanguinity, and that when such blood becomes extinct, the inheritance tiself must fail; aence, too, by the feudal system, the tenant, on attainder of treason or felony, not only for-feited his land, but his blood was held to be corrupted or stained, whereby every inheritable quality was en-tirely blotted out and abolished, so that no land could thereafter be transmitted from him or through him in a course of descent. If a bastard dies intestate and a course of descent. If a bastard dies intestate and without issue, his lands escheat to the lord of whom they are held; for bastards being regarded as multius filti,—the sons of nobody, are looked upon as having no blood in them, or, at least, no inheritable blood. Recheats are commonly divided into two classes,—propter defectum canguints,—from deficiency of blood; and propter delicium tenentis,—through delinquency of the

bolder, where, by attainder, the blood of the person attainted is so corrupted as to be rendered no longer inheritable. The attempts of recent legislation have been to modify this law, and now no attainder for felony, except treason or murder, extends to the disinheriting of any heir, or to the prejudice of the right or title of any person other than the right or title of the offender during his natural life.

ESCUTCHEON, es-kutsh'-un (Lat. scutum, Fr. sousson, a shield), in Her., the name given to the shield on which armorial bearings are depicted. The shield may be of any form, but the shape generally adopted is that of a square, a brace with the central point turned outwards, or two lines projecting outwards, and inclined to each other at a very large obtuse angle, being used at the bottom instead of a horizontal line to connect the sides. The armorial bearings of a lady entitled to bear arms, being unmarried, or a widow, are em-blazoned on a shield in the form of a lozenge.

ESCUTCHEON OF PRETENCE.—When a man marries an heiress or co-heiress, he places the armorial bearings of his wife's family on a small shield, exactly in the centre of his own coat. This shield is called an escutcheon of pretence, and signifies that the children by such a marriage inherit the coat armour of their mother's family, as well as real property, and are the representatives of that family, as well as that of their father. On the death of the father, the children bear the armorial bearings of their mother's family quarterly

with the paternal cost.

ENDARS, ez'-dräs, is the name given to two apocryphal books of the Old Testament. In the list of apocryphal books in the sixth article of the Church of England they are called the third and fourth books of England they are called the third and fourth books of Esdras, Ezra and Nehemiah being sometimes called the first and second books of Esdras or Ezra. The books of Esdras (i.e. the third and fourth) never formed any part of the Jewish canon; they were re-jected from the canon by the Council of Trent, and are not read in the service of the Charch of England. They are commonly supposed to have been originally written in Greach by some Hellenistic Jawa. though They are commonly supposed to have been originally written in Greek by some Hellenistic Jews, though some imagine that they were first written in Chaldee, and afterwards translated into Greek. It is uncertain when they were composed, though it is generally agreed that the author wrote before the time of Josephus.

Esparso, or Spanism Gazes, espar-to (Sp.), is a species of grass, the stipa, or Macrochlou tenucissima, obtained from Africa and Spain. In Spain it is plaited and used in many ways, and a great deal of the cordage employed in the navy of that country is made from it. Within the last few years esparto has been largely imported into this country for making paper. It grows in bunches or tufts from two to four feet in height, "and consists of a long, flat, lanceolated leaf or blade, which, as the sap descends and the plant ripens, takes which, as the sap descends and the plant ripens, takes a cylindrical form. It is pulled up from the roots, exposed to the sun, and, when dry, laid in small bundles, and these again, for facility of carriage, into larger ones, which are transported in carts, or more generally on donkeys' backs (both in Spain and Africa, in the uncultivated and wild districts of the country where the plant exists, being, comparatively speaking, without roads) to the port of shipment.—(Ure's Diet.) At the beginning of the year the plant was selling at £5 per ton, and about 50,000 tons of it are now imported.

ESOX. (See PIPE.) ESPLANADE, es-plon-aid' (Fr.), in Mil., the term sp-plied to the open space that should surround a citadel, and intervene between the main ditch and any fortifications that may be thrown up round the town near which the citadel is situated. The esplanade should be about five or six hundred yards in breadth, measuring from the crest of the glacis.

ESQUIMAUX Don, es'-kwe-mo.—This animal is rather BEQUIMAUX Dog, et ... kwe-mo.—This animal is rather larger than the English pointer, but appears less, en account of the shortness of its legs. It has oblique eyes, an elongated muzzle, and a bushy tail, which combine to give it a wild and wolfish appearance. The colour is generally a deep dun, obscurely barred and patched with darker colour. In the northern parts of America and the neighbouring islands, this animal is the only beast of hurden. With a team of dogs harnessed to his aledge, the Esquimaux may soud over the snow at a rate of sixty miles a day, and this for several days in succession. The driver has no reins; but he has a long whip, and that answers every purpose, as the old and knowing dogs are always put to the fore, and know their way across the vast blank anow-fields with unerring correctness; and should the "shafters" prove refractory, a few cruel lashes with

the fore, and know their way across the vast Diank anow-fields with unerring correctness; and should the "shafters" prove refractory, a few cruel lashes with the reindeer thong quickly bring them to a sense of duty. It is a rule, however, among sledge-drivers to use the whip as seldom as possible; not, it must be confessed, from motives of humanity; but the chastisement of one of the team generally leads to considerable confusion; the dog struck at once falls to biting and mauling his next neighbour, and so the traces become entangled, and a general fight ensues, neally ending in the upsetting of the vehicle and the loss of an hour in getting things in order again.

Exquulty, es-kwire' (Fr. covyer, a shield-bearer; Lat. scutifer).—In the middle ages and the days of chivalry, the esquire was a young gentleman of good family in immediate attendance on a knight, who carried his shield and performed many duties in his capacity, which were not, however, of a menial nature. The esquire first served as a page in the knight's household. When he was old enough, and possessed of sufficient strength and skill to hear arms, the page was promoted to the rank of esquire, and attended the knight tournaments and in the battle-field. He eventually became a knight himself, after exhibiting such provess became a knight himself, after exhibiting such prowess in the field or elsewhere as might entitle him to claim the spurs and other insignia of a knight. In the present day, the title of esquire should give the hearer precedence over gentlemen properly so called, who are entitled to hear coat-armour; but is of no value, owing to its universal assumption by those who have no claim whatever to attach it to their names. The following are those who are properly entitled to this appellation:—The sons of younger sons of dukes and appellation:—Ine sous of younger sous of earls, viscounts, and barons; the eldest sons of these younger sons just mentioned, with those of baronets and knights; barons; the eldest sons of these younger sons just mentioned, with those of baronets and knights; officers of the royal household; captains in the army and navy, and all officers above the rank of captain; doctors of law and medicine, barristers, sheriffs of counties, magistrates while in the commission of the peace, and Royal Academicians.—Ref. English Cyclopadia,-Arts and Sciences.

Essay, es'-sai (Fr. essai, a trial, an attempt), in Lit., is a name given to a species of composition which is characterized by greater latitude of construction is characterized by greator latitude of construction than is allowed in any other species of composition, and it differs from narrative in generally treating of mental or moral qualities. It is defined to be "in mental or moral qualities. It is defined to be "in general, a short disquisition on some subject of taste, philosophy, or common life" It is thus applied to philosophy, or common lite." It is thus applied to periodical papers published at different times on sub-jects of general interest; as morals, criticism, matters of taste, &c. This species of writing may be said to have of taste, &c. This species of writing may be said to have originated in this country in the beginning of the last century, by the publication by Addison and Steele of the Tatler. The Tatler was succeeded by the Spectator, to which Addison was the chief contributor; and the Spectator was followed by the Rambler of Dr. Johnson. Numerous works of this class appeared in the latter half of the 18th century; but they have since gone out of fashion.

ESSEMES, es'-seenz (Gr. essenoi), a sect which existed among the Jews during the lifetime of Christ. They are not mentioned in the New Testament, but they are described by Josephus and Philo. The authentreity of the account ascribed to the latter is, however, doubtful, as a work in his name, "De Vita Contemplativa," is proved to have been written by a Christian plativa," is proved to have been written by a Christian monk. According to Josephus, the Jews were divided into three sects,—the Pharisees, the Sadducees, and the Essense. The Sadducees were essentially a polithe Essenes. The Sadducees were essentially a poli-tical party, and the Essenes were those who carried out the views of the Pharisees to an extent which made them ridiculous in the eyes of the party from which they sprung. Levitical purity hemmed them in with so many restrictions that it soon became necessary for them to live in retired and lonely places.

They took no part in public affairs, and population, apent their lives in contemplation. They adopted celibacy, and had no individual property. In matters of belief they held the Scriptures in the highest reverence, interpreting it, however, by an allegorical system of their own they believed also in the immortality of the soul. Out of Raseniam, in the stage of Sabæism, resulted Islamism, in the full development of whose tenets and practices several of the principal

rites of the Essenes are preserved.

ESSENTIAL OILS, es-sen'-skil (Lat. essentialis), in Chem., a term applied to the odorous principles of plants. They are also called volatile oils, to distinguish them from the fixed oils. Chemically speaking, they are either hydrocarbonsor oxidized hydrocarbons, they are either hydrocarbonsor oxidized hydrocarbons, and oils containing sulphur. They are extracted from different parts of plants, some plants yielding two different essential oils. Thus the orange yields two distinct essential oils, one from the flower, the other from the peel of the fruit. They are prepared in different ways, either by enfleurage, by pressure, or by being distilled with water. The principal use of essential oils is in perfumery; but certain of them are used for flavouring, and in medicine. It would be impossible to give even a summary of the almost infinite number to give even a summary of the almost infinite number of essential oils: if the reader is curious on the subject. he may find a great deal of valuable information respecting them in Piesse's "Art of Perfumery." 3rd edition.

ESSOIGN, es-soin' (old Fr. essonier, to excuse), in aw, denotes an excuse for him that is summoned to appear and answer to an action, or to perform suit to a court baron, &c., by reason of sickness, infirmity, or other just cause of absence. A party might essoign himself three times by sending a substitute to explain the reason of his non-appearance. Formerly the first return in overy term was, properly speaking, the first day in that term, and was usually called the esseign day of the term, as on that day the court eat to take casoigns or excuses for such as did not appear according to the summons of the writ. Esseigns are now rarely resorted to, and are almost unknown in prac-

ESTABLISHED CHURCH, es-tab'-lishd (Fr. établir, to fix firmly), is a church established and maintained by a state for teaching religion in a particular form. History shows that in almost all nations an intimate connection has been maintained between religion and the nection has been maintained between religion and the civil government. In Greece, in Rome, among the ancient Druids, or the modern Chinese or Japanese, thesame thing is evident; the Church gives its support to the State, and the State gives its protection to the Church. The government established among the ancient Jews was a theoreacy, and among the Mohammedans, the Koran may be said to-comprise both the civil code and the religious creed of the people. Hence, perhaps, the idea of an established religion is to be sought for in the inner nature of man. The subject. sought for in the inner nature of man. The subject, however, is one which has been very much discussed, and on which much diversity of opinion exists. In the New Testament there is nothing laid down on this sub-ject; yet, from the stress that is laid upon respect for civil governments, some have drawn an argument in favour of establishments. In the early ages of Christianity, the Church was a stranger to any alliance with the civil powers; but, subsequently, the connection between the two became very intimate; and to this cause may be attributed most of the errors into which the Church fell. These, at length, became so great and manifest as to lead to the Reformation. When the Protestant states separated from the Church of Rome, each set itself to establish a Protestant church of its own, in itself to establish a Protestant church of 118 0wn, m conformity with certain prescribed tenets, which were frequently, also, enforced upon others. In England, as well as in other countries, the measures concted against non-conformity and dissent were very oppressive; but these have, from time to time, been abolished, and now dissenters, in this country, may be said to enjoy nearly all the privileges that are compatible with an established church. (See DISSENTERS.) The great objection to an establishment arises from its tendency to suppress freedom of opinion, and to pre-scribe in what men's consciences ought to be the sole guide. In some of the continental countries this is attempted to be remedied by the State granting en-

dowments to all of the more important of the Christian sects. In favour of church establishments is alleged the necessity that there is for a state to preserve and communicate religious knowledge. It is argued that the knowledge and profession of Christianity canno be upheld without a dergy; that a clergy cannot be supported without a legal provision; and that a legal supported without a legal provision; and that a legal provision for the clergy cannot be constituted without the preference of one sect of Christiaus to the rest. The endowments of the established church in this country are not strictly derived from the State, which, indeed, has rather robbed than enriched it, but were chiefly bestowed by individual liberality to the Church in early times, and were transferred to the Anglo-Catholic Church at the time of the Reformation, though the right of appropriating them to one particular sect,

when there are so many others, may be questioned. ESTATE, es-tait' (Fr. etat, Lat. status), in Law, is that title or interest which a man has in lands, tenements. or hereditaments, and is the condition or circumstance in which an owner stands with regard to his property. The leading distinction to which estates are subject is that of legal and equitable, the first being properly cognizable in the courts of common law, though noticed also in those of equity, and the second being properly cognizable only in the latter courts. A legal estate is usually considered in a threefold point of view : (1) With regard to the quantity of interest which the tenant has in the tenement; (2) with regard to the time at which that quantity of interest is to be enjoyed; and (3) with regard to the number and connection of the tenants. As to quantity of interest, estates are either freehold or less than freehold. Freehold estates, again, are divided into freeholds of inheritance and freeholds not of inheritance. Of estates less than free hold there are three kinds: (1) Estates for years; (2) estates at will; and (3) estates by sufferance. Besides these several divisions of estates in point of interest, there are what are called estates upon condition,—those whose existence depends upon the happening or whose existence depends upon the happening or not happening of some uncertain event. They are of two kinds,—estates upon conditions implied, and estates upon conditions expressed. As regards the time of their enjoyment, estates are either in posses-sion or in expectancy. Of expectancies, there are at common law two sorts,—one called a reversion, the other a remainder. With reference to the number of persons entitled to the enjoyment, estates may be in severalty, joint tenancy, coparcenary, common, entireties

ESTATES OF THE REALM .- The three estates of the realm are the three branches of the legislature,—the lords spiritual, the lords temporal, and the commons.

Esting, Book or, est-ther, is one of the historical books of the Old Testament, placed after that of Nehemiah. It contains the history of a Jewish maiden, by name Esther, who became the wife of the Persian king Ahasuerus. As to the authorship of the book, nothing is with certainty known, nor are there any data on which to form a reasonable conjecture. By some it has been ascribed to Mordeon, by others to Ezra, or the high priest Joschim; but, in any case it appears to have been written soon after the events which it narrates had taken place; and it has this peculiarity, that the name of God does not once occur in the whole book. The difficulties regarding the authenticity of this book have been much exaggerated. It has always been received as canonical by the Jews and regarded as one of the most precious portions of their sacred scriptures. Some difference of opinion exists as to what Persian monarch is referred to crists as to what Persian monarch is referred to under the name of Ahasuerus; but the probability seems to be in favour of Kernes. The entire narrative corresponds with what we know of the manners and customs of the Persian court, and of oriental orneity; while the origin of the feast of Purim shows very clearly that the occasion thereunto must have occurred in Jewish history. In the Septuagint there are a number of additions and details in this book, which Jerome, in the Vulgate, placed at the end of the book, and Luther in the Apocryphs. That these additions an spurious there can be little doubt. Esroperul, es-tep-pel (Fr. estoupir), in Law, is an impediment or bar of action arising from a man'r own act. Estoppels are of three kinds:—(1) By matter

of record, as where a judgment has been given in a court of record, the parties to the suit are estopped from afterwards alleging matters which would be confrom atterwards alleging matters which would be contradictory to the record; (2) by deed or matter of writing, no person being allowed to dispute his own solemn deed, which is therefore conclusive against him and those claiming under him, even as to the facts recited in it; and (3) by matter in pais (in the country), that is, by transactions between the parties not evidenced by record or writing; as livery, entry, &c. The principle of estoppel is, that what a man has once solemnly alleged, he should not be afterwards suffared to contradict. suffered to contradict.

ESTOVERS, es-to'-verz (Fr. estoffer, to furnish), in Law, is the liberty which the owner of an estate for life or a tenant for years has of taking a necessary supply of wood from the estate for the use or furnisupply or wood from the estate for the use or furni-ture of his house or farm. The Saxon word bote is used in the same sense; and therefore house-bote is a sufficient allowance of wood to repair or to burn in the house; plough and cart bote are for making and repairing instruments of husbandry; and hay or hedge bote is for repairing hays or hedges. These botes must be reasonable, and if a tenant takes more than is needful for these purposes, he may be punished for waste. for waste.

ESTRAYS, es-traiz' (Nor. estrayer), in Law, are such valuable tame animals as are found wandering in any manor or lordship, the owner of them being unknown. manor or foreignp, the owner of them being unknown. The law gives them to the king, as general owner of the soil; but they are most commonly given by special grant from the crown to the lord of the manor. In order to become absolute property, they must be proclaimed in the parish church and two market-towns. next adjoining to the place where they were found; and if not claimed within a year and a day, they belong

to the king or his substitute. ESTREAT, es-treet' (Lat. extractum), is a true copy INTERAT, esercer (Lat. extractum), is a true copy or note of some original writing or record, and especially of fines or amercements, entered on the rolls of a court to be levied by a bailiff or other officer. When recognizances are taken, as for appearance to prosecute or give evidence in cases of felony or misdesecute or give evidence in cases of reconjulances be broken, the recognizance becomes forfeited; and being extreated, or extracted, and sent up to the Exchequer, the party and his sureties, having now become the king's absolute debtors, are sued for the several sums in which they are respectively bound. The barons of the Exchequer have power to discharge, mitigate, or compound estreated recognizances and forfeitures, except such as are incurred before justices of the peace.

ceps such as are incurred octore justices of the practice. Estuary, cs-th-are (Lst. extuarism), is a term in Geog. which was originally applied to any bay, creek, frith, or arm of the sea, in which the tide cheed and flowed (Phiny, Epist. lib. 9, ep. 33); it is now used, however, to denominate those parts of river channels which are constitutions to the account of the continuous to which are contiguous to the sea or ocean in which the water is salt or brackish. For the term estuary to be rightly applied, the ebb and flow of the tide must be distinctly perceptible, and there must be little or no current. In the British isles the estuary of the Humber is the largest.

Humber is the largest.

Ethno, e-te-re-o (Gr. etaireia, society), in Bot., a kind of fruit, examples of which are afforded by the strawberry, ranunculus, and Adonis. When the achenia (see ACHENIUM) borne by a single flower are so numerous that they form more than a single whorl or series, they constitute collectively an eterio. In the anumerous and Adonis the achenia are placed on a series, they constitute collectively an eteric. In the rannuculus and Adonis, the achmin are placed on a convex thalamus of a dry nature; in the strawberry they are placed upon a fleshy thalamus. The so-called seeds of the strawberry are in reality so many separate achmin; while the part to which the strawberry owes its value as a fruit is merely the succulent thalamus. In the fruit of the rose, the achienia, instead of being placed on an elevated thelamus, are situated upon a concave one, to which the calvx is attached. This modification of the ordinary etserio is regarded as a distinct fruit by some botanists, who have distinguished it by the name of Cynnarhodum. In the raspberry and blackberry, a kind of eterio is formed of a number of little drupes or drupels, crowded together upon a dry thalamus.

ET CATERA, et-set'-e-ra, a Latin phrase, which kas

### Etching

become thoroughly Anglicised. It is usually written fc., and means and so on, and so forth. As an abbreviation it is of great use in writing.

ETCHING. (See ENGRAVING and ELECTRO-ETCH-

ETCHING UPON GLASS. (See GLASS.)

ETRINITY, e-ter'-ne-te (Lat. aternitas), an attribute of the Deity, the existence of whom, according to the true principles of religion, is without beginning or end. It is a negative idea clothed with a positive name. To whatever it is applied, it supposes a present existence, and it is the negation or denial of any beginning or end to that self-same state of existence. As applied to the to that self-same state of existence. As applied to the Deity, it has not been controverted by those who seknowledge a deity at all. On the common basis of argumentative philosophy, there never could have been a time when nothing ever existed, as assuredly that state of nothing impulpable must necessarily have continued up to the present time. In strictness, however, we have nothing to do with duration prior to that of the visible world; it is sufficient for us to know that the contriver existed before his handiwork. Eterity have the property being influite, is inconceivable by our fluits unity being influite, is inconceivable by our fluits unnity being influite, is inconceivable by our finite un-derstandings; at the same time, we cannot imagine an infinite being to exist without it. There is a distinction made between an anterior and a posterior eternity; the latter belongs to beings whom God pro-

eternity; the latter belongs to beings whom cod pro-poses to preserve for ever, the former to himself alone.

—Ref. Paley's Natural Theology.

ETHAL, e'-that (formed from the first syllables of ether and alcohol), in Chem.—When spermaceti is saponified, it yields ethal instead of giveerine, as is the case with the ordinary fats. It is a white solid, fusi-ble at 118° Fahr., and soluble in alcohol, crystallizing in plates as it cools. It possesses the constitution and properties of a true sloohol, and stands in the same relation to pulmitic acid that ordinary vinous alcohol does to acctic acid.

does to acetic acid.

ETHER, ê-ther (Lat. ather), in Chem.—Ether is used as a generic term to denote a series of organic bodies having the general formula Hn.+1(OnHn+1)O. They are looked upon as being derived from corresponding alcohols by the abstraction of one equivalent of water; or, in other words, they are regarded as the oxide of a radicle represented by the formula within the brackets, of which their alcohols are the hydrated oxides. This theory has undergone a modification of the years the theory has undergone a modification of late years, the followers of Gerhardt laying it down as a principle that the equivalent of an other when existing alone is double, and that its compounds are formed by substitution. There are strong reasons in support of this theory, as will be seen when we consider the double and compound ethers. Ethers are subdivided into,-1. Simple ethers, of which ordinary vinous ether may be taken as a type  $(C_aH_aO)$ ; 2. the double ethers, which consist of two equivalents of different ethers united, as the methyl-ethylic ether  $(C_aH_aO,C_aH_aO)$ ; and the comments of the ether of methyl-ethylic ether (C,H<sub>2</sub>O,C,H<sub>3</sub>O); and the compound ethers, which contain an equivalent of an ether united to an equivalent of an acid or halogen, and correspond to saits; thus nitric ether is C,H<sub>2</sub>O,NO<sub>5</sub>; hydrochloric ether, C<sub>2</sub>H<sub>3</sub>Cl. From the formulae given of the double and compound ethers, it will be seen that they may be considered as double atoms of the original ether, in which one atom is replaced by another ether in one case, and by an anhydrous acid or a halogen in the other. In common parlance, ether is generally taken to mean the ordinary sulphuric ether, as it is improperly termed, from being obtained from alcohol by the action of sulphuric acid. Pure ether is an extremely limpid, colourless, transparent ether is an extremely limpid, colourless, transparent fluid, very volatile, and refracting light with great power. Its colour is peculiarly powerful and penetrating if inhaled; at first producing exhibitation, and fiterwards stimulating effects, followed by insensibility to pain. Its use as an annesthetic has been superseded by chloroform. It has a specific gravity of 0.721 at 55° Fahr., and boils at 94.8° Fahr. It is used for producing cold artificially by rapid evaporation. Its upour is extremely dense, sinking heavily in air; great care should therefore be taken not, to pour it out with a flame below it: otherschean explosion of a dangerous a flame below it; otherwise an explosion of a dangerous character might ensue. Mixed with certain propor-

#### Ethics

cial application is as a solvent for pyroxylin in the manufacture of collodion. In analysis it is used as a solvent for fats. Ether was formerly prepared by mixing two parts of alcohol and one of sniphuric acid, and heating the mixture in a retort until it began to mixing two parts of anoma and the string the mixture in a retort until it began to blacken; a quantity of alcohol, equal to half that used, was added to the mixture, and the distillation continued as long as the ether distilled over. The process of Boullay, or the continuous process, as it is termed, is now generally used. Equal measures of alcohol and sulphurio acid are heated in a capacious retort, which is connected with a reservoir of alcohol in such a munuer that, as fast as the ether distils off, a corresponding amount of alcohol makes up the deficiency. The process cess is continued until thirty times the original amount of alcohol is used, the sulphuric acid acting over and over again as the agent by which an equivalent of water is abstracted from an equivalent of alcohol.

water is assirated from an equivalent of alcohol. (See Etheristication.)

Etheristication, e-ther-if-e-kai'-shun, in Chem.—
The process by which the same amount of sulphuric acid serves continuously for the abstraction of an equiacid serves continuously for the abstraction of an equivalent of water from an almost indefinite number of equivalents of alcohol, has been much discussed amongst chemists. Numerous researches have been made on the subject by Liebig, Mitscherlich, Graham, and others, and the general explanation arrived at is that the sulphuric acid unites with the alcohol to form sulphethylic acid and water. The sulphethylic acid then splits up into ether, which distils over, and sul-phuric acid, which again unites with the alcohol to form a second portion of sulphethylic acid, which in its turn decomposed. The great difficulty in admitting this view arises from the circumstance that sulphethylie acid should be first formed and then immediately decomposed, under precisely similar circumstances of temperature. Mitecherlich and Graham consider that the sulphuric acid acts in a calalytic maner, simply inducing composition in other bodies by its pressure, somewhat in the manner of a ferment.—For a fuller discussion of this very interesting subject, the reader is referred to Miller's "Elements of Chemistry," vol. iii. 3rd edition.

ETHICS, vol. in. ord edition.

ETHICS, eth'-isk Gr. ethica, from ethics; Lat. mos, mores, manners, or moral conduct), signifies, strictly, both in ancient and in modern speech, the doctrine of morals. This branch of knowledge has been divided by modern writers into two parts, the one comprehending the theory of moral science, and the other its practical doctrines. On the former side the first part investigates that principle of our constitution by which we are led to form the notion of moral distinwhich we are not form the notion of moral manni-tions; and on the laster side it inquires into the proper object of moral approbation. In other words, this science endeavours to give an answer to the ques-tion.—Is it by the same faculty that perceives the existence of truth and falsehood in other departments. of knowledge, or by a peculiar power of moral percep-tion, which is pleased with one set of qualities and displeased with another, on which the peculiar obli-gation of moral conduct is founded? What is the common quality or qualities, in short, belonging to all the different forms of virtue? Is it benevolence,—is it sympathy,—is it a rational self-love? Thus the scope of the one question is to ascertain the origin of our moral ideas; that of the other to refer the various moral phenomena to their most simple and general laws. Again, the practical doctrines of morality com-prehend the rules formed to direct human conduct, and the best means of compassing this general end. These two questions, when properly treated, seem to exhaust the entire theory of morals. Ethics, then, is a word which shall be employed in the succeeding article as altogether synonymous with moral philosophy. One of its best and latest German expounders observes, "The best name for this science is Ethic, orderves. The nest name for this science is lethic, or doctrine of morals, as is clear from the relation of this word to the three fundamental conceptions of morals,—law or duty, virtue, and chief good."

Bihics, or morals, has properly to do with action rather than with thought; and hence the name of the active remess that Reid and Stawart have supplied in their character might ensue. Mixed with certain propor-tions of sir, it forms a highly-explosive compound. It dissolves readily in alcohol, but very sparingly in water. action belongs exclusively to morals and not also to It is much used in medicine; buttis principal commer-the intellectual faculties; but that it belongs more 794

obtrusively and overfly to this department than it does to the other. Action in general is twofold: it is either instinctive and constitutional, as hunger, thirst, and the love of sex; or it is voluntary and designed, as the love of sex; or it is voluntary and designed, as when men pursue a course of ambition, or spend a long life in the endeavour to master some department of knowledge. Of those two lines of action, one is necessary, compulsory, and absolute while it lasts; while the other is contingent, voluntary, and relative. I may resist the strong urgings of ambition or of glory; but I cannot resist the demands of hunger. It is at the choice of Napoleon whether he laws Elba or no sthough it is quite necessary that hunger. It is at the choice of Napoleon whether he leave Elba or no, although it is quite necessary that he should have his breakfast on that inauspicious the while the one class of morning. It thus appears, that while the one class of actions is necessary to our existence, the other actions is necessary to our existence, the other is by no means necessary; and many persons would be all the happier to resist those urgent longings which besirge their wills and often carry them captive. Another consequence follows from this consideration, which it is all-important to note on the present occasion,—that it depends altogether on whether the will of man be consciously free, as to whether his acts can carry with them any moral responsibility. If a stone accidentally falls on my head and materially injures me, I do not blame the stone, I simply lay the charge on my own suit fortune. If I am bitten assured by my neighbour's doe. I may pronounce the severely by my neighbour's dog, I may pronounce the dog dangerous to the lieges, I cannot hold him guilty of assault. But if I am knocked down and robbed by of assault to have him up before the magistrate and punished; for unless he be an imbedile or a madman, he cannot tor unless he be an innectic or a medinan, he cannot set up a plea of moral incompetence, which everybody would arge in favour of the previous cases. Nor am I responsible for an act performed by me while I was under moral or physical compulsion; for by being so constrained, my will, my voluntary guiding power, is deprived of its accustomed freedom, and I am no longer at liberty to act as I please. It hence appears that for all practical moral purposes, the will must be consciously free, otherwise there can be no responsibility. (See Ferenom and Necessity.) And not only so; the other faculties, which always go to aid the moral jndgment in pronouncing its awards, must be in a normally healthy condition, otherwise no meral blame is attachable to a vicious act more than to a virtuous one. Were our law courts capable of publicly recognizing the more delicate shades of character and of guilt that frequently come before them for judgment, and were human nature better able to appreciate the finer traits and more delicate lineaappreciate the inner traits and more delicate linear-ments of men's dispositions, there can be little doubt that our civil and criminal codes would experience an entire modification of their peculiar rigour against peculiar offences and crimes often committed with but little moral cogitation and with but little moral crift. For how often are men's passions at these whomguilt. For how often are men's passions strong where their moral perception is not of the highest! And when malevolent emotions become heated, do they on the bind men's minds to every other consideration but what this wicked passion points them to? Then the history of the growth and formation of human character is nearly a terra incognita, and such should always be taken into account in anything approaching a perfect code of moral, or even of criminal law. Whatever is calculated to shake or to confirm the will in it moral, andeavour is calculated. confirm the will in its moral endeavours, is calculated to shake or to confirm the comparative perfection of the moral character. With the view, accordingly, of the moral character. With the view, accordingly, of ascertaining and of classifying the various sources of our activity, various ethical inquirers have analyzed our various propensities into nearly the following principles:—1. There are our appetites of hunger, thirst, and sex, which take their rise from the body, and which ally us with the brutes. To those natural appetites belong the acquired ones; such as the liking for tobacco and other parceties, and for in-

desire for wealth, for dress, for equipage, for retinue, and for furniture, which are all readily explainable on the principle of association.—3. Then there are the affections, or those active principles whose direct and ultimate object is the communication of pleasure or of pain to any of our fellow-creatures. These are distinguished, according to their tendency, into benevolent and malevolent affections. To the former class belong the parental and the filial emotions,—those of kindred, the parents and the man emotions,—more of situated, love, friendship, patriotism, universal benevolence, pity, gratitude, &c. It is to be remarked, regarding those affections, that this classification is simply offered from its convenience, not from its being exhaustive. There is one peculiarity observable with respect to there is one peculiarity observable with respect to these emotions, that, accompanied as they all are with exquisite pleasure, they have, nevertheless, nothing selfish in their origin. This has been fully demon-strated by many writers. It is a remark of Bishop Butler, that the final cause of so much agreeable emotion connected with the exercise of benevolence is, in all likelihood, meant to induce us to cultivate with peculiar care a class of our active principles so immedutely subservient to the happiness of human society.
Our malevolent pass, ms, or affections, are usually distributed into hatred, jealousy, envy, revenge, and some kinds of resentment. As the former class of affections are always accompanied with pleasant emotions, so the malevolent ones are invariably attended by disagreeable ones. It is obvious from this, that the latter are only ones. It is obvious from the that the latter are only to be used with a great degree of caution, and on no occasion in greater intensity than the urgent necessities of the case demand. They are like those poisonous cures that are sometimes administered to us to restore our frames to their accustomed health. If the prescribed dose be overstepped, the chances are that must atone for our rashness with our lives. Such would be the constitution of man, were no inheritance of reason or of conscience to fall to his share. Reason, however, renders the nature of man altogether different from what it would otherwise be. It is by this faculty, in its multifarious forms, that man is capable of availing himself fully of his past experience in avoiding those temporary pleasures that he knows will be suc-ceeded by a corresponding suffering, and in submitting to those lesser ills of life which he knows will ultimately minister to a greater accession of good. In a word, he can form that more enlarged and liberal idea of happiness with which every cultivated man is acquainted, ness with which every cultivated man is acquainted, and be can deliberate about the best means of attaining to this wished-for goal. It is impossible to pronounce the word happiness in the hearing of any man without at the same time enkindling in his mind various ideas, more or less attainable, of an exceedingly desirable object.—4. Self-love, accordingly, or that species of desire which longs for personal happiness as an end in itself, is a rational principle of our nature, altrogether legitimate and presiseworthy when ness as an end in resen, is a radonal principle of our nature, altogether legitimate and praiseworthy when kept in its own place. The pursuit of one's interest in an enlightened way is perfectly lawful as an ethical end; it only becomes unlawful when, by its excess, it shuts out that essentially higher principle which men have variously termed the moral faculty, the moral sense, the conscience. Self-interest, or self-love, differs from selfishness, which always indicates a peculiarly low and vulgar state of character, which is only content with the perpetual gratification of a morbid sensuality. This enlightened regard to our own interest was, by many of the ancient philosophers, regarded as the whole of virtue, and they thought they had accomplished the duties of sages when they had nau accomplished the duties of sages when they had had down rules, of more or less particularity, for the attainment of this "supreme good," this summum bonum. Nor is it to be wondered at, that they placed the whole of virtue in this prudential self-regard; for the two principles—that of self-interest and of the moral founds. thirst, and sex, which take their rise from the body, and which ally us with the brutes. To those natural appetites belong the acquired ones; such as the liking for tobacco and other narcotics, and for intoxicating drinks. All stimulants are of this class.—2. There are the desires, which may be conveniently distributed into the desire for knowledge (curiosity), the desire of society, the desire of seaseem, the desire of intoxicating drinks, the desire of seaseem, the desire of society, the desire of seaseem, the desire of intoxicating drinks, the desire of seaseem, the desire of into experience that we learn the connection of virtue and happiness; and hence virtue, the cause, must certainly precede the existence of self-love, as the effect. The emptions which accompany the two principles differ both in degree and in kind. This may be readily established by any one at all acquainted

with what takes place in our public theatres. The audience here, from the enthusiasm of their combined judgment, impress one more forcibly than any amount of individual talking. And accordingly, the slightest throad of pure morality which the dramatist contrives to weave into his piece, at certain stages of the action, raises the passions of the crowd into transports, and forces tears from grave, sensible men. In all languages, the words employed to denote the ideas of duty and of interest are distinct. The to kalos and the kathekon of the Greeks, and the konestum and utile of the Latins, express exactly what we mean when we speak of duty and of interest. A similar conclusion likewise finds countonsoe in the early period at which speak of duty and of interest. A similar conclusion likewise finds countonsace in the early period at which our moral judgments make their appearance, it being always a considerable while before it is possible that we should be capable of forming the general notion of our own happiness. To escape the force of some of the foregoing arguments, it has been alleged that this notion of right and wrong, as a separate existence in human nature, was first of all discovered by philosophers and politicians, and the influence of education has effected the rest on the growing mind of the race. Now education is no doubt a powerful instrument; but there is no example on record that can be pointed to to illustrate the case of a new creation being to to illustrate the case of a new creation being implanted in men's minds by means of this potent organon of culture. No doubt sufficient allowance must be made for the different circumstances of mankind in different periods of society, and for the diversity of their speculative opinions, as well as for the different moral significance of the same action, per-formed under different systems of external behaviour. But while education may, and does, in this way modify in important respects the moral sentiments of mankind, as well as their opinions regarding the beautiful and the sublime, we would be far from maintaining that it can effect such wonders as to create our notions of right and wrong, or our sesthetical ideas. Now, lest there should still linger in some men's minds a hesitation to accept of this ethical principle as contrasted with self-regard, we beg to refer to a very weighty sentence of Bishop Butler's on the subject, as calculated, so far as any historical authority can be so, to carry persuasion to the most wavering mind. This singularly able moralist says, in his second dissertation on "the Nature of Virtue," "For as much talk has been disputed wherein virtue consists, or whatever ground for doubt there may be about particulars, yet in general there is in reality a universally acknowledged standard of it. It is that which all ages and all countries have made profession of in public,—it is that which every man you meet puts on the show of, it can effect such wonders as to create our notions of that which every man you meet puts on the show of,— it is that which the primary and fundamental laws of all civil constitutions over the face of the earth make all civil constitutions over the face of the carti make it their business and endeavour to enforce the practice of upon mankind; namely, justice, veracity, and regard to common good." Having now vindicated the fact of moral perception as an essential part of the human constitution, the next question that demands our attention is the foundation and the formation of this distriction.

a feeling, or as a judgment, that this fact of ethical a feeling, or as a judgment, that the fact of ethical appreciation is experienced, or is it something different from all these? While many wise and great men have argued on all of these sides, it becomes a moralist of the present day to proceed with cantion. The truth is, that the act is somewhat Protean in its complexion. Now that one looks at it through hard, metallic intellectual glasses, the phenomenon turns up as determined an outline as a sum in arithmetic could; again that we view it through the somewhat hazy medium of emotion, it looms as large and palpuble as the renowned "bogle" of the Brocken. And if a half renowned "bogle" of the Brocken. And if a half sceptical and rather clumey analyst takes the fact between his fingers, the chances are that, like the sand on the sea-shore, it will crumble through insensibly, and leave nothing behind. Still, the fact of the rightness and wrongness of actions remains to be accounted for; and unless we make the faculty an indistinguishable compound of reason and feeling, it is hard to say what other equally unobjectionable analysis of it can be offered.—2. Of the emotions excited by the contamplation of moved heavity and deformity by the contemplation of moral beauty and deformity, some are necessarily pleasurable, others are necessarily painful. Those qualities in good actions which excite agreeable emotions in the observer, form what some moralists are inclined to call the beauty of virtue, and the opposite feelings, as the deformity of vice. The emotions thus arising from the observation of moral beauty and of moral deformity are so much more exquisite in their agreeableness, as well as more harrowing in the pain they bring with them, than any that arise from the perception of material forms, that the Socratic school used to aver that the literal signification of the words beauty and sublimity arose primarily from the perception of the qualities of mind. (See BRAUTY.)-3. When a virtuous action has been performed in our When a virtuous action has been performed in our presence, we cannot check our benevolent affections from going forth in its behalf; and if we attempt to do it, it is most likely to be at the expense of our own peace of mind. When, again, we witness an act of cruelty, of selfishness, of oppression, of decoption, of cunning, we are inspired by a feeling of extreme hostility toward the delinquent, and can hardly restrain our indication from heading forth against him. In our indignation from breaking forth against him. In our own particular case, if we can occasionally approve of our conduct to the extent of looking forward with confidence to the approbation of a higher tribunal, the connuence to the approparion of a nigher virtual, the sense of ill-desert, on the other hand, is usually so absorbing as often almost to destroy this just anti-cipation of future reward in us. While our sense of the merit and demerit of actions must impress us anew with a sense of the intimate connection between virtue and happiness, yet we are not to suppose that always, when we have done well, prosperity will attend us as a matter of course. It takes a man of sense, nay of wisdom, to acquiesce calmly in the lot that Providence, in its inscrutable ways, has assigned to him. It is a vulgar error to expect that good or evil fortune always accomments in strend lines are good and avil extints. of upon mankind; hamely, justice, veracity, and regard to common good." Having now vindicated the fact of moral perception as an essential part of the human constitution, the next question that demands our attention is the foundation and the formation of this distinction. One class of moral theorists leans to the emotional or subjective view of the origin of our ethical judgments, another class patronizes the intellectual or objective view, while a third class is of opinion that moral laws owe their origin entirely to theoretic legislation. As this distinction cannot be entered an here, some account will be found in the article Conscience of the different opinions maintained respecting the origin of the moral faculty of the chief writers who have treated of this question throughout the history of the world. In analyzing the good or badactionsperformed by others, or even when we need to one own minds when we do some commendable action or are guilty of some reprehensible one, are we not conscions of the following things?—1. The appreciation of a certain rightness in actions. 2. A feeling of satisfaction, or the opposite, varying in degree according to the delicacy of our moral sensibility.

3. The appreciation of the merit or demerit of the agent. 4. The idea of merit or demerit of the agent. 4. The idea of merit or demerit of the agent. 4. The idea of merit or demerit of the agent. 4. The idea of merit or demerit of the agent. 4. The idea of merit or demerit of the agent. 4. The idea of merit or demerit of the agent. 4. The idea of merit or demerit of the agent. 4. The idea of merit or demerit of the agent. 4. The idea of merit or demerit of the agent. 4. The idea of merit or demerit of the agent. 4. The idea of merit or demerit of the agent. 4. The idea of merit or demerit of the agent. 4. The idea of merit or demerit of the agent. 4. The idea of merit or demerit of the agent. 4. The idea of merit or demerit of the agent. 4. The idea of merit or demerit of the agent. 4. The idea of merit or demerit or demerit o implies, in the last remove, the idea of human duty. As Butler says, it is the violation of a known obligation that renders man obnerious to pushment, it is not his foreknowledge at the certainty of that punishment. We accordingly conclude that the moral faculty is essentially different from all other powers of the mind; and while the slightest violation of its authority fills us with removes, the greater our sacrifices in its behalf fill us with unspeakable satisfaction and triumph. Human duties are ordinarily divided into those relating to the Daity, to ourselves, and to others. Respecting the first, see Natural Tenology. — Ref. Butler's Bermons; Sir James Mackintosh's Ethical Dissertation; Reidla Active Powers; Stewart's Active and Moral Powers; Dr. Thos. Brown's Lectures on the Philosophy of the Human Mind; Kant's Metaphysic of Ethic; Fichte's Destination of Man; Dorner's Lectures on the Scotlish School; Jonfrey's Ethica, &c. which speedily deliquesce in the air, giving rise to ethionic soid. ETHIOF'S MINERAL, ethe-ops, in Chem. (H.S.), sub-sulphide of mercury. It is obtained as a black powder by transmitting a current of sulphuretted hydrogen through a solution of a mercurial subsalt, or by tritu-

white milky crystals of ethionic anhydride are formed,

rating 18 parts of moist sulphur with 200 of mercury.
ETHNOID BONE, eth'-moid (Gr. ethmoides, from eth ETHNOTO BOTH, eth'-moid (Gr. ethmoides, from ethmos, a sieve), in Anat., is one of the bones of the head, which is exceedingly light and spongy, consisting of many convoluted plates, which form a network like a honeycomb. It is somewhat cubical in form, and is situated between the two orbitary processes of the frontal bone, at the root of the nose. The olfactory nerves shoot down through the numerous small perforations of this bone to the organ of smell.

ETHNOGENETH, eth-nog-re-fe (Gr. ethnos, a nation, and graphe, description), is that science which treats of the manners, custome, religion, forms of government, and other peculiarities of different nations, and which is commonly regarded and treated as a branch of convent accounts.

of general seography.

ETHNOLOGY, etk-nol'-o-js (Gr. ethnos, nation, and logos, discourse), is that science which treats of the varieties [of the human race, their history and disvarieties (of the human race, their history and dis-tribution, their languages, physical and mental charac-teristics; arranging and classifying them, noting their points of similarity or dissemblance, and having in view the difficult problem of the unity or non-unity of the human race. "The chief ethnological problems," the human race. "The chief ethnological problems," says Dr. Latham, "generally expressed, are those of (1) the unity or non-unity, (2) the geographical origin or origins, (3) the antiquity, and (4) the futurity of mankind,—questions all closely connected with each other with the chief of th 797

of ethnology is of very recent origin, and is still in a very imperiect state. On the great question of the of emissions is a very recent origin, and is suit in a very imperient state. On the great question of the unity or diversity of the race, ethnologists are divided into two great schools. Of the one the representatives may be said to be Prichard and Latham, in England; of the other, Morton and Agassiz, in America. Peter Camper, a distinguished Dutch anatomist of the last Camper, a distinguished Dutch anatemist of the last century, was the first who attempted to lay down on scientific principles a method of distinguishing be-tween the different races of mankind, from the form and aize of the skull, by what is known as the facial angle. The head being viewed in profile, a line is drawn through the meatus auditories of the ear to the base of the nose, meeting another toushing the most prominent part of the osure of the forehead, and falling down to the most advanced portion of the upper jaw. The nearer the angle thus formed approaches a faming down to the hose angle thus formed approaches a right angle the greater, as a general rule, is the intellectual development of the individual; and this is found to be generally the case, not only as regards than, but also among the lower animals,—the smaller the facial angle the lower are they in the scale of intelligence. One great objection to this method was the lower animals are count only one feature of the skull; intelligence. One great objection to this method was its taking into account only one feature of the skull; to remedy this, Blumenbach fixed upon a number of characteristic peculiarities; and to him we owe the division of mankind into the five following classes:—(1) the Caucasiau, (2) Mongolian, (3) Ethiopian, (4) American, (5) Malay. Cavier reduced the five classes of Blumenbach to three,—the Caucasian, Mongolian, and Ethiopian, treating the Malay and American as subdivisions of the Mongolian. He referred the original sents of the human race to the mountain-chains,—the Caucasian to Mount Caucasus, the Mongolian to the Altai mountains, and the Negro to the chain of —the Caucasian to Mount Caucasas, the Mongolian to the Altai mountains, and the Negro to the chain of the Altai. Dr. Prichard, who was the first that brought to the study of this subject a large knowledge of languages as well as of physiology, regards the banks of the great rivers, and not the mountains, as the primary seats of the different races. "The cradles, or nurseries, of the first nations." he says, "seem to have been extensive plains or valleys, traversed by navigable channels and irrigated by personnal and fertilizing streams. Three such regions were the accesses tilizing streams. Three such regions were the scenes of the earliest civilization of the human race." "In one of these the Semitic or Syro-Arabian nations ex-changed the simple habits of wandering shepherds for the splendour and luxury of Nineveh and Babylon. In a second the Indo-European or Japetic people brought to perfection the most elaborate of human dialects, destined to become in after-times, and under different destined to become in after-times, and under different modifications, the mother tongue of the nations of Europe. In a third, the land of Ham, watered by the Nile, were invented hieroglyphical literature and the arts, in which Egypt far surpassed all the rest of the world in the earlier ages of history." These three divisions do not correspond to the three indicated by the form of the skull, which he makes the swage or hunting tribs, the numerical convenience tribs. or origina, (3) the antiquity, and (4) the futurity of mankind,—questions all closely connected with each other, and all mutually illustrative of each other; questions to which the phenomens of classification and the several ethnological methods are subordinate." Ethnology differs from authropology in that the latter deals with the relations of man to the other members of the animal kingdom, whereas the former regards the differences that exist among the different varieties of the human race. The latter requires only a single pair for its study, the former presupposes variety of races; and the greater the variety the further its boundaries attend. It partities of history, but, unlike ordinary history, which deals with actions, it treats of the effects of physical agencies upon man,—soil, climate, nutrition, and the like; going back to a period long anterior to the existence of written records, and, unlike history, arguing from affects to causes, from the known to the unknown. In this way ethnology is the standy of chimology, as well as physical geography, so the satisface of languages; and physical geography, so the satisface of languages; and physical geography, so the satisface of languages; the satisface of physical influences upon differentiases. The satence of history in the first of these has been added thus not a proposition of the skull, which he makes the base of each other; divisions do not correspond to the first of the scale partitions of the luman family. In the first of these the calls proposition of the luman family. In the first of the scale partitions of the luman family. In the first of the scale partitions of the luman family. In the first of the sate many the fact, and what he terms pyracidia scale is what he calls proposition of the luman family. In the first of the luman family. In the first of the luman family. In the first

Ethnology 4 French anatomist reported as the model of perfection, and at the same time the probating of the human family. This were is insulational analysis of the human family. This were is freely the property of the second group are time highlighted or Hamilton, reporting ever in inturban ness and wealth on their own rish and. This third group is the Indo-European, Japetin, or Arisis rees, promprising the Hindoos, Permising Algham, Reports, Armentans, and the nations of Khinope, with their larger to clonies. "The physical differences between all these nations, though no little the probability are not greater than nost persons will think sufficiently explained by reference to climate and to-diversity of food and of manners." The great central region of High Asis is this bitted by five noand to diversity of food and of manners." The great central region of High Asis is inhabited by five no shadie races, belonging to the Mongolian division of sufficient, said observed by pyramidal heads and broad faces. These are —(1) the Ugrian, in the N. W., from whom the Magyars are believed to have descended, and of which the Finns, Laps, Ostaks of the Odi, and thise Siberian tribes, are varieties; (2) the Turkish, with their nomadic tribes, and the Ostomau branch; (3) the Mongolian, including the Calmucks; (4) the Tungmaian, in the mountainous region between Lake Bulkai and the river Okhotsk; (6) and the Bhotys race (often termed Tartars), inhabiting a great part of Thibet and the Himalayan chain. Beyond the central region occupied by the five nomadic races are various tribes of people, spread over the races are various tribes of people, spread over the lower countries of northern Asia, and over the cold plains which are traversed by the Siberian rivers and power countries of northern Asis, and over the cold plains which are travared by the Siberian rivers and border of the tey Ses. They belong to the same great division of mankind as the Tarters, whom they resemble in some of their leading characteristics, particularly in the form of the skull. He terms them lehtbyophagi or dishing tribes. To the same type of the human species as the nations of High Asis he long the Chinese, Koreuns, Japanese, the races of the Indo-Chinese peningula, and the aborigines of India, distinct from the Hindoes (who belong to the Indo-Chinese peningula, and the aborigines of India, distinct from the Hindoes (who belong to the Indo-Chinese peningula, and the shoring as afterwards occupied by the Indo-European and Syro-Arubian races there existed a more antient stock of inhabitants, also of eastern origin, but who had migrated westward at an archief date, and to whom he gives the name of Allophylians. These, when displaced by the invaders, stock reduce in the mountainous parts; and to them belong the Cancasians, the Iberians of the Tytenacu, the Berbers of the Allas chain, and the Grandles of the Cancary inlands. Of the black races of the interjor of Africs, the principal are the Sensonshire, including the Mandagean. of the sterior of Africs, the principal are the Sene-gambias, including the Mandingoes and the Foolahs. The true negro characters are most strongly marked that portion of the coast which encircles the projecting region of Western Africa to the inmost angle of the Bight of Benin, the centre of the slave trade. The Hottentots and Bushmen of South Africa in many respects recemble the nomedic Mongolians of Asia; the Hottentots and Bushmen of South Africa in many respects resemble the nomatic Mongolium of Asia; the warlike Caffres are said to combine the prominent forehead and nose of the European, the thick lips of the Kegro, and the high cheakbones of the Hottentot. Among the African races, the Abyssinian, a fine dark, but not negro race, is interesting as having preserved, "in the midst of Moslem and pagan nations, is peculiar literature and its ancient Christian church," and having remains of a wide-spread Judaism and a language approaching the Hebrew. The Oceanic races Pricing alvides into Malayo-Polynesian, Pelagian Negroes, and the Affoorians of the New Guinea group of all de (which include the Australians). The American races are distinguished from those of the old world by their anguages. The Magican tribes, which, according to having arrived on the century, found the region inhabitation, in sensions which have left the splendid ruins of Palangus as among whom were the Othomi, remarkble for their monosylatic ideas. The Equinman and Palangus as among whom were the Othomi, remarkble for their monosylatic ideas. The Equinman and Palangus as among whom were the Othomi, remarkble for their monosylatic ideas. The Equinman and Palangus as among whom were the Othomi, remarkble for their monosylatic ideas. The Equinman and Palangus as account of the continuance, extend across the accustor portion of the continuance.

Pthnology.

Payment on the Pacific event the dark Californians and the tribes of the hostic west mast, and in South America the Andrew Series, the Brazilio-Gazanai, and the meditorsument or centres groups. Dr. Leaburn adopted another chaselfornion in his "Natural History of the Variation of Mas." London, Dr. Lethum adopted another describents a his "Natural History of the Varieties of the London, 1850; but as this diffuse in some respects from that given in his article on lithuslogy in the "Racyclopedia Britannics," we shall follow the lattice, as being the more recent. He proceeds upon the decourse—[1] that, as a matter of fact, the languages of this surface are referable to a common origin, and (2) "that, as a matter of logic, this common origin for those whe speak it." He maintains that this primal facts evidence will not be overridden by the confinciant phenomena of physical and moral differences. "Bat the physical characters of our kind are permanent is argued from such a fact as the mummles of autient Egypt giving as the same cryanization that is given by the modern Copts;" and, "again, that comparatively light complexions are found in some of the hottest parts of the world, whereas dark once are found in comparatively cool ones, passes for an argument invery igus complexions are found in some of the houtest parts of the world, whereas dark once are found
in comparatively cool ones, passes for an argument
against the effects of heat on the skin." He divides
the human race into three great divisions.—(1) the
Asiatics and Northern Europeans, Polynosians, and
Americans; (2) Contral and Southers Europeans;
(3) Africans and South-western Asiatics. In the
first division are (4) those populations whose physical conformation is either typically or subtypically Mongol, having been generally recognized as
such; comprising (a) languages monosyikals, as the
Chinese, Siamese, Hurmose, (b) Turanians—languages
other than monosyllabic, groups, (1) the Mangolan, (2)
the Turk, (3) the Ugrian, (4) the Paneus, (5) the Teninsular;—(B) Iramans; groups, (1) the Mangolan, (2)
Paropamisans, (3) Armenians, (4) Roscurians (4.5; the
Caucasians of Caucasus, or Caucasians in the limited,
proper, and convenient sense of the territy;—(C) Indians;—(D) the Oceanicstock, (a) Amphinesis, (1) Protonesians, (2) Micronesians, (3) Polynesians, (4) Malagais; (b) Kelemonesians, (1) Papuans of New Guines,
(2) Tamanians, (3) Australians;—(E) Americans,
comprising, in groups yet undetermined, she Kagumaux, Algonkins, Iroquois, Sioux, Woocous, Padicus,
& the Tearst South-Americans families of weight the maux, Algonkins, Iroquois, Sioux, Woscons, Paduoss, &c.; the great South-American families, of which the ze.; the great South-American ramines, or when the limits are the most defined are, (1) the Curiciusas, (2) the Cariba, (3) the Gusrim, the Chapo, the Pampa, and the Chileno groups, being of somewhat less though still of considerable magnitude. The languages of the second division—central and southern Europeans—fall into four divisions: (1) the Basks, who inhabit the weatern Pyrenese, the north of Spain, and the south of France; (2) the Skipetar, or Albanians, who inhabit Albania, and whose language isolates them; those many hold that it can be connected with those of the fourth class; (3) the Celts (t. e. Welsh, Bretons, Gaels, and Manxmen; and (4) Sarmatians, Gormans, Latins; and Greaks, who are Indo-Karopean in the attrictest sense of the term. In the third division, the African and couthwestern Asiatic, there are: (1) the Semitic, (2) the Nilotic, (3) Kafre, (4) Negro, (5) Hottentot, Dr. S. G. Morton, whose principal works are the Grasia Americana (1839) and the Creasia Mappilicae (1844), divides man into the following groups in his catalogue of skulls, more, however, for convenience of study and examination than as an attempt at assenting classification;—(1) Caucasian group, with the Scandingvian, Finnish or Tchudic, Stavid, Anglo-Saton, Applo-American, Celtic, Sciavonic, Pelasgie, Senaitic, Berber, Nilotic, Indostenic, and Indo-Chisees races; (2) Mongolian group, with the Readmanies, (3) Malay group, with the Randings and Toltecan races; (4) American group, with the Scandings are senses; (5) Malay group, with the Malayan and Polynesia. Romanies, Romanies, Mariana, dec. Freedoms Agreest, in the Trynes of Haminot, by Magre group, with the native Africans, Hovas, and Afocras races; (6) the barbarous and Toltecan races; (5) Malay group in the Malayan and Polynesia with the strength of the trype of man, maria and the primordial forms of the type of man, maria and distinct primordial forms of the type of man, maria and distinct primordial forms of the type of man, maria and distinct primordial forms of the type of man, maria and distinct primordial forms of the type of man, maria and distinct primordial forms of the type of man, maria and distinct primordial forms of the type of man, maria and maria ann handons of the type of man, maria and maria ann handons. division—central and southern Europeans—fall into four divisions: (1) the Basks, who inhabit the western

distinct types of man. A fee gives a steels of the neutral provinces of the fannes tingdom and their relation to the different types of man. He describes them according to the following resinus: (1) Arctio, inhabited by Ryperbricais; (3) Keistis, by Mongoli; (3) European, by white men; (4) Antimosan, by American Indians; (5) African, by Rubians; by American Indians; (5) African, by Rubians; Abyestinans, Foolahs, Negroes, Hottemtots, and Boujeanen; (6) Rest-Indian or Malayan, by Papusas and Australians; and (9) Folymerican, by Papusas and Australians; and (9) Folymerican, by Papusas and Australians; and (9) Folymerican, by South-Sea Islanders, In the "Indigenous Races of the Earth" (1877), Messrs. Nott and Gliddon give suredunographic tableau, in which the races are divided zoologically, according to the injureains of Agassis; they are also grouped physiologically (after Desmoulias, Achille Compte, and O'Halley) into sixty-five famines,—even belonging to realm 1 of Agassis, twelve to realm 2, sixteen to realm 3, fourteen to realm 4, eight to realm 5, three to realm 3, two to realm 7, and tirre to realm 5. The same realms 8, two to realm 7, and three to realm 8. The same realms b, two to reamy, and three to reams. In esame reams have also their cervesponding classes, arranged linguistically, after Alfred Maury, Crawfurd, Logan, &c. A detailed account of the different Asiatic, European, and African race is given by Dr. Lathum, in his "Descriptive Fthuology," 2 vols. 1859. These remarks will show in low imperfect a state the science of other control of the control of t nology still is; and those who wish to pursue the subjest further, we would refer to the works cited. have depicted in Plates XLIX, and L., the various types of mankind. Fig. 1, which is the portrait of an Esquimant, supplies the typical signs of the Arctic race; fig. 2 is a Chinese head, as exemplying the Monyol race; fig. 3 marks the European race; fig. 4, monpor roce; ing. 3 mark the towopean race; ig. 3, the head of an American chief, typifies the American race; ig. 5 is the American race; ig. 5 is the Nepro type; fig. 6 is the Hottentot type; fig. 7 the Malay type; and fig. 8 is the Amstraisan type. The shape of the skull is shown underneuth.

ETHYN, eth'-ile (Gr. aith.r, air; ule, the material of which a thing is made), in Chem. (C. II., C. II.,), the second and most important member of the series of alcohol radicles. When a mixture of granulated zince and iodide of ethyl is heated to 300° in a tube from which the air is exhausted, a number of compounds are formed, ethyl, the radiole in question, amongst them. By breaking the tube under water, the liquid compounds are ejected in a gaseous form; and by carefully collecting the portions which come off last, the ethyl is obtained nearly in a state of purity. Ethyl is a conourless gas with slightly ethereal smell. and burns with a luminous flame. It may be liquefied at 38° Falir, by a pressure of 24 atmospheres. Frank-land estimates its boiling-point at -9°. It is the radicle of ether and alcohol, and as such deserves especial notice. It dissolves readily in alcohol, but

not in water.

ETHTLESE, OF OLEFIANT GAS, eth'-e-lene, in Chem. (C.H.), the second hydrorarbon in the olefant gas series. Those hydrogarbons are described under the head of OLEPIANT GAS

ETIOLATION, stoo-lai'-shun (Gr. aitho, I shine), in Rot., when all the green colour of a plant is absent, it is described as etiolated. This condition is produced

by the want of light.

by the want of light.

Enguyerns, et.s.ket (Fr., a ticket), denotes the forms
of manners and behaviour that prevail in polite society,
established by usage and good breeding. The names
probably derived from the custom that prevailed, on state occasious, of delivering a ticket to each person, instructing him as to the part which he was to take in the ceremony. At no time, probably, was the spirit of etiquette so predominant and so tyrannical as at the court of Louis XIV. of France. At the present day, the ctiquette of courts is becoming less and less strict; and in private society many of the old and absurd forms are given up. "Riquette," says a writer on this subject, "is the barrier which society draws around itself as a protection against offences the law cannot touch: it is a shield against the intrasion of the impertinent, the improper, and the vulgar."

Erow Cottags, «-ton, eiteated at Eton, in the county of Buckingham, was founded by Henry VI, in 1440, and was dedicated to "the Blessed Marie of Etons, beside Wyndssore." Henry had been moved to the foundation of this college by the successes of William of Wyksham's noble foundations at Winchescourt of Louis XIV. of France. At the present day, the

ber and Orford, established, about fifty years before. Bien Gellege and King's College, Cambridge, were modelled upon Wykeham's plan. The disjinal foundation seems to have provided fat treasily the establishment and twenty-five provided fat treasily the establishment of the king. In 1445 the number of alumines was reduced from twenty-five to thirfeen, that of the acholan being raised to exventy, at which it now stands. King's College, Cambridge, was also founded by Henry VI., and was designed to receive the best of the Eton foundations as accounted countried. Within the last few years this close connection, has been the last few years this close connection, but hen severed, twenty-four out of forty-eight scholarships at King's being appropriated to Eton collegers, the remainder, together with all the fellowships, being virtually thrown open. The first provest of Eton was William of Waynflate the head maker of Winchester. William of Waynfiete, the head master of Winchester, and founder of Magdalen College, Oxford, At the present day to distinct consists of a prover, rice-provest, six ich in remark assistant maters), whead master, a lower master, assists as distinct conducts (chapisius), with choosings and almostomen. The college, whick obtained several majors and advovations from its founder, received several more from Edward IV. Suce that period it has been associated and prosperous. At present there are about 200 boys, a large proportion of whom are members of the aristocracy. Those boys who do not belong to the seventy scholars on the foundation are called "oppidans," and board in the house of the assistant masters and William of Waynflete, the head master of Winchester. board in the houses of the seniciant masters and dames. The collegers wear black gowns but not college caps, as at Westminster, and their expenses are less than those of the "oppidans," who constitute the wealthy and uristocratic element of the school. In the appearance of the college itself there was nothing striking, except the size and elegant character of the houses, until the recent erection of new schools of the houses, until the recent erection of new schools and the splends restorations of the hall and the chapel, which is on the model of that of King's College, Cambridge. Among the old customs kept by at Kton College may be mentioned the "Montem," held on Whit-Tuesday every third year. The boys all appeared in fanoy costume, headed by the suptain. The last montom was held in 1944, when the contributions levied upon the spectators, or capitain's eath," as it was called, amounted to £1,338. Is 36. Many eminent and ilustrious men have been educated at Eton. These of the than, Six Educet and Horse Walpole, Lord North, and the duke of Wellington, were Etonians. Ptonians.

ETRUSCAN ARCHITECTURE, a-trus-kda.—There are but very few cristing remains of the constructive works of the ancient Etrascans from which we are enabled to judge of the professors, which this people had attained in the art of building. It is, however, certain that all works of a public nature were eminently characterized by solidity of construction, and were probably plain and devoid of elaborate sculptured decorations. The and devoid of elaborate sculptured decorations. The Tuscan order of srchitecture, the plainest and most massive in style of the five classic orders, is named after this people; and although no example remains at the present time to show that it was positively originated and adopted by them, yet we may justly believe that the Bomans derived it from a country believe that the Bomans derived it from a country which was the oradic of early Italian art, and that it forms a fair standard by which we may judge of their skill and progress in the art of building. Their temples are said by Vitravius to have been gamil, and rectangular or or cular in form. They were consenented with figures in brouze and stone, and the walls of the interior were probably panelled, and covered with paintings like those of the chambers that here been discovered in the sampleheal recorded in the sampleheal recorded in the sampleheal recorded in the sampleheal recorded. paintings like those of the chambers that have been discovered in the sepulchral mounds that are so common in Tuscany. Their private houses were low covering a large extent of ground, and surmounted with measive entablatures. Although there was but little architectural display in their buildings, the Etruscans had reached a high degree in the arts of painting and sculpture. The wase found in the Etruscans tombs are elegant in form, and the weapons and organizes are often of heautiful and elaborate construction. The principal archimetegical remains of another Etruscans that there been discovered in the same localities are often of heautiful and elaborate construction. The principal archimetegical remains of another Etruscans that the surface of the rocks at Viterbe and Rocthia; the supplicators at Entry,

### Etruscan\* Vases

also hewn out of the solid rock, and the numerous sepulchraistumuli. The roofs of many of the cham-bers found in these tunnil are smoled, and a Rome bers found in these tangul are stedled, and & Rome derived her architects and knowledge of building from Etruria, we may consider the Miruscans as the originators of the arch and vaulted roofs in Europe.—Ref. Ferguscow's Hausdood of Architecture; Dennir's Cisies and Consteries of Etruria.

ETRUSCAN VARIN.—The Etruscans asselled in the arts, and their vasas remain as models of design to this day. There is a conjecture that these beautiful vessels were not designed and manufactured by the ruling race in Effortia, but by their bondmen or seria. By whatsoever race they were made, the ware of

ETRUSCAN VASE.

which the vases were formed was both glazed and

# Eluchariat

ornamentation was a friess of small figures about an insamentation was a friess of small figures about an inch high, made from a glindrical stamp revolving in the risg. In the year 3817 same very remarkable specimens of Errmean raises were found under beds of lava near the Alban take, confishing the sales of the dead. They were indicated in larger vases with two handles, for protection. The pottery of the Errmeans competed with that of the Greeks in the Italian market. The great resemblance which exists between the Erruscan vases and those of Corinth is a proof that Erruscan vases and those of Corinth is proof that Erruscan derived from Greece her skill in modelling clay and the elegant drawing with which her vases were adorned. The manufacture was carried on between the years 600 n.c. and 395 n.c., the latter date being that of the fall of the Erruscan was a lucrative one; it is probable that Rome derived all lucrative one; it is probable that Rome derived all ber ware from this source.

ETIMOLOGY, et.c.mol'oge (Gr. etumos, true, and logos, description), is that part of grammar which treats of words by themselves, of their classification, treats of words by themselves, of their classification, their formation, and the alteration of their forms by derivation and infection. It teaches the deduction of one word from another, and the various modifications by which the sense of the same word is diversified. The recent philological researches have given to this department of grammar a much more extensive and important field of inquiry, by bringing together whole groups of languages, and showing the connection existing between them in word and form. (See Grammar, PRILOLOGY.)

EUCALYTUS, w-kd-lip'-tus (Gr. eu, well; kalupto, I cover), in Bot, a gen. of the nst. ord. Myrtuces, consisting of trees having hard wood, alternate, entire, coriaceous leaves, and yellow flowers, growing in corymbs. They are natives of Australia and Tasmania. The most important species is E. resimifers, the

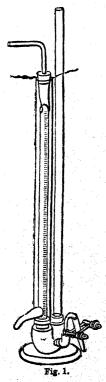

The most important species is E. resinifera, the iron-bark, which yields on incision an astringent substance called *Botany Bay kino*. This contains a peculiar substance, to which the name Encodyptis has been given. It has been employed as a remedy in diarrhos. The leaves of E. mannifera and other species spontuneously exude a saccharine substance resembling manna, and hence termed Australian manna. It is said to drop from the trees in pieces sometimes as large as an almoud. The secretions of the Eucalypti are commonly of a gummy nature, and on this account the trees are sometimes called gum-trees. The bark of some of them separates in fibrous layers; and this peculiarity has also obtained for them the name of stringy-bark trees. They frequently attain a prodigious height,—200 feet or more, the trunks being destitute of branches to a height of from 100 to 200 feet,

EUCHARIST, w. kurriet (Gr. eucharistia, the giving of thanks), is used, in a theological sense, to denote the sacrament of the Lord's Supper. The term is not found in the New Testament; but in the history not found in the new Testament; but in the autory of the institution of this ordinance, the word excharistesas occurs; and this probably led Justin Martyr and others to adopt the word, gratitude for divine mercy and grace being a chief requisite in those who would worthily partake. During the first three centuries, the Eucharist was celebrated every Sunday; but afterwards it came to be administered only three times in the year,—at Baster, Whiteantide, and Ohristmas. In early times, the Bucharist was cele-brated in the churches with closed doors, to the exclusion of all but the initiated, and it ordinarily took place at night. The use of tapers on the occasion is traced to these nocturnal celebrations. The mixing which the vases were formed was both glazed and plain. The shape of the vessel was generally an imitation of the Greek. That description of glazed vase which the Lislan antiquaries call "the national" was of pale clay, and glazed with a black colour of an ashen or leader any. The shape of the shape are call "the national" was essential to the due performance of the first saythelogy. These vases were baked at a continuous say that a block the 7th bread was that in common use; but about the 7th bread was that in common use; but about the 7th bread was that in common use; but about the 7th bread was that in common use; but about the 7th bread was that in common use; but about the 7th bread was that in common use; but about the 7th bread was that in common use; but about the 7th continuous and including the continuous of the 1st was a continuous of the 1st was an antipolished expensity. The body of the vase was underly a state of the state of the 1st which was and lips were also decreased with representations of the call the same of the state of the 1st which was and lips were also decreased with representations of the animals, mostly in imitation of the metal-works of Greeces and asse. and divinity, is contained in either species, and in the smallest particle of each. Hence they infer, that whether the communicant receives only the bread or the wine, he enjoys the full benefit of the sacrament. In the early church, communicants appear to have received the sacrament standing.—See on this subject a learned and interesting article in Knight's English Cyclopædia, section Arts and Sciences, article "Communical".

EUDIOMETET, u-de-om-e-tre (Gr. su, well; dies, air; metron, measure), is the art of analyzing and investi-gating gaseous bodies by means of the instrument called the endiometer. It, for instance, it be desired to estimate the amount of oxygen in the air, to three measures of atmospheric sir contained in the eudio measures of sunoppures of pure hydrogen,—detonate, and upon the cooling of the vessel, observe the absorption; divide its amount by three, and the quotient will represent the amount of oxygen. This method was represent the amount of oxygen. The method was invented by Voita. The best form of eudiometer is that invented by Dr. Ure. It coneists of a siphon formed of glass, with legs of nearly equal length, open at one extremity, which is funnel-shaped, and hermetically sealed at the other, which is supplied with plantage of the property of tinum detonating wires. The siphon leg, which is scaled up, is graduated into 100 equal parts or sub-divisions of the cubic inch. In order to make use of this simple justrument, it must be filled with mercury and inverted in the pneumatic trough; a convenient supply of the gas to be measured is inserted, and having applied a finger to the orifice at the end of the open leg, the tube is removed from the trough and inverted, so as to transfer the gas to the sealed leg, where its

quantity can be accurately measured. A portion of mercury must then be poured from the open end of the siphon, so as to leave a space of about two inches; and, closing the aperture again, detonate by the electric spark. The included portion of air serves as a spring, and, on withdrawing the thumb, withdrawing the thumb, which closed the open aperture, and adding mercury to restore the level, the change of bulk produced in the gas by de tonation can easily be read off. Any liquid or solid that is required for the analysis of the residuary gas may then be passed up into the closed end, and different results may thus be arrived at. An improved form of endiometer has recently been invented by Mr. Josiah P. Cooke, jun., of the United States. This apparatus is easily made with a common iron casting, well known to steam-fitters as a "return bend." Any machinist will easily adupt this casting to the required use by attaching to it, as shown in fig. 1, a circular iron plate to serve as a stand, by also screwing on to one side an ordinary "elbow-joint," and at the same time by ourefully rimming out the three apertures so as to present smooth surfaces for the adhesion of the india - rubber stoppers. Into one of the openings

### Eudiometry

opening we fasten, in a similar way, an open glass tube. In the opening of the sibow-joint we secure, with a perforated india-rubber stopper as before, that convenient substitute for a stop-cock so well known to chemists as a "nipper tap." Last of all we obtain a tubulated tube, like that shown in fig. 3, of such size that it. ""Ill cores the adjustment tube and fit that tubulated tube, like that shown in lig. 2, or such size that it will cover the endiometer tube, and fit the upper end of the same india-rubber stopper by which the last is accured in its place. The upper end of this outer tube is also closed with a perforated stopper, as shown in the figure, and fine platinum wires, connecting with the wires of the endiometer, pass between

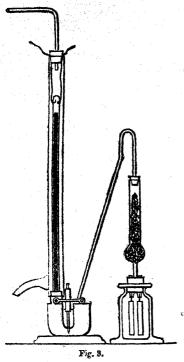

the stopper and the glass. The lower end of the outer tube should nower and of the outer tune snown not fit too tightly around the rubber stopper, so that it can easily be removed when not wanted; moreover, all the stoppers should be made of such length that while perfectly tight they can easily be removed for cleaning the tubes. It is also best to place round the upper end of the endiometer tube an india-rubber ring quite nar-row, but sufficiently thick to fill the annular space when the outer tube is in its place, and also perforated with a number of small holes, so that the steam or vapour employed in the experiments may pass freely. This ring confines the eudiometer tube, and gives greater solidity to the apparatus. greater solutive to the apparatus.
The indis-rubber joints, if well made, give great flexibility to the apparatus, and enable it to withstand quite rough usage. The eudiometer being thus mounted. mercury is first poured into the open limb, which is then closed with an india-rubber stopper, and the mercury transferred by inclining the apparatue to the closed limb, this process being repeated until the eudiometer tube is full. The excess of mercury is now drawn out of the tube by the tap, and this tube having been re-moved, the instrument is left as represented in fig. 3. The endiometer is now ready for receiving

the mixed gases which are passed up into it from a simple decomposing sell, as shown in the figure, the excess of mercury overflowing into any con-venient vessel. The open tube is now replaced and the outer tube is secured in position. It is next the outer tube is secured in position. It is next necessary to raise the temperature of the eudiometer tube to a point considerably above the boiling-point of water, and maintain it at this temperature during the reat of the experiment. This is most conveniently done by passing through the outer tube the vapour of amylic alcohol (fousel oil), which may be generated in a flask placed at one side, and connected by a glass tube with the upper end of the apparatus. The tubulature at the lower end of the tube should at the same time be dipped into the mouth of a glass bottle, into which the alcohol may flow as fast as the vapour is condensed, and, since the latent heat of this vapour is very small, this simple method of condensation will be found amply sufficient. As soon as the temperature of found amply sufficient. As soon as the temperature of the eudiometer tube is constant, which can easily be the endiometer tube is constant, which can easily be told, because the mercury column will then remain at a constant height, mercury must be poured into the open tube, or withdrawn from it by the "nipper tap," until the level is the same in both limbs of the apparatus. It remains now only to note the volume of the confined gas, and to explode it by passing an electric spark through the platinum wire already noticed; first, however, tightly closing the end of the open tube with its india-rubber stopper. When the stopper is removed, and the mercury columns again brought to the same level, it will be found that the volume of the confined gas has been reduced one-third. The resultof the "return bend," we fisten with a perforsted the same level, it will be found that the volume of the india-rubber stopper, a common straight endiameter confined gas has been reduced one-third. The result, tube, such, for example, as is ordinarily used in Bunhowers, is always a little too small, because aqueous sen's method of gas analysis; while into the second wapour, even at the boiling-point of amylic alcohol,

# Endiometry

132°, does not exactly obey Mariotte's law, and is somewhat more condensed than the mixed gases by the atmospheric pressure. It would be better to employ the vapour of a liquid having a still higher boiling-point, but the results with amylic alcohol are sufficiently accurate for a lecture experiment. This form of endiometer, although originally contrived for the lecture-table, has proved to be of still greater

value in the laboratory in all processes of gas analysis for which such an instrument is required. It is not only very cheap, simple, and easily repaired, but also equally as accurate as the most complicated apparatus. It can be used in a room of the most variable temperature, for by passing a current of water or of steam, as the case may require, through the outer tube, the temperature of the eudiometer tube may be easily temperature of the endiometer tube may be easily maintained absolutely constant. The various gases are passed in as shown at fig. 3, and through the same openings the re-agents used in the process of analysis are readily introduced. By replacing the open tube as in fig. 3, and bringing the two mercury columns to the same level, the residual volumes may always be read off under the atmospheric pressure, and at a constant temperature indicated by the thermometer placed in the annular space between the thermometer placed in the annular space between the thermometer placed in the annular space between the tubes. Or, on the other hand, by varying the height of the measury column in the outer tube, we may reduce the same volume, and measure the difference of tension according to the method of Regnault. This form of endometer is especially adapted for the admirable methods of gas analysis devised by Buassa. The absorbent balls used by him are most readily introduced when the apparatus is arranged as shown in fig. 3, and the volume of aqueous vapour, formed after combustion, may easily be measured by replacing the current of cold water through the outer tube by a current of free steam. In

#### Branch

insure that all the water is vaporised, and also in order to avoid the somewhat uncertain correction arising from the difference of temperature of the two-limbs of the apparatus. This correction, which in most cases is insignificant, becomes important when steam is used, and it is then best to measure directly the difference of level between the mercury in the open mouth of the iron cistern (fig. 3) and that in the tube. This we do by the millemeter divisions on the eudiometer tube with the sid of a very simple contrivance. A split ring of blackened sheet brass, carrying a bent steel wire, is alipped down over the outer tube until the end of the wire just touches the surface of the mercury. The vertical height of this simple measure being known, we have only to add to it the the mercury. The vertical height of this simple measure being known, we have only to add to it the measure being known, we have only to and to it the height of the mercury column above the upper edge of the ring, in order to know the exact difference of the level. Of course care must be taken when the measurement is made that the mercury column is vertical; but it is unnecessary to dwell on such obvious precautions, which are essentially the same with this apparatus as those fully detailed by Bunsen in his work on "Gasometry." The above apparatus, as represented in fig. 3. may also be used with great in his work on "Gasometry." The above apparatus, as represented in fig. 3, may also be used with great advantage in Gay-Lussac's process of determining the density of vapours. The method of using it is very simple:—After a weighed amount of the liquid under examination inclosed in a thin glass bulb has been passed up into the endiometer tube, it is readily consisted in the resulting the content of the convention of the con verted into vapour by passing steam, or the vapour of some liquid of a still higher boiling-point, through the outer tube. All the measurements required in the determination are now easily made. The temperature is measured by a thermometer, placed in the annular space between the two tubes, and the difference of level of the mercury in the two lumbs of the instrument may be most accurately determined by means of

ment may be most accurately determined by means of a cathetometer, niede by the simple contrivance just described.—Ref. Brande's Manual of Chemistry.

RUGENTA, u-je'-u--2 (in honour of Prince Eugene, of Savoy), in Bot., a gen. of the nat. ord. Myrtacex, composed of trees and shrubs with opposite entire leaves, axillary white flowers, and black or red berries. E. pimenta is the most important species. Its dried unripe fruit constitutes pimento, or Jamaica names or in most familiar heavens allarios. The popper, or, in more familiar language, allspice. The latter name is given to it because it is thought to have combined the flavours of cinnamon, clove, and nutmeg. combined the havours of combined of eve, and nutmeg. It is used as a spice, and in medicine as an aromatic stimulant. Its properties are dependent on the presence of a volatile oil. The rose-apples of the East, which are much esteemed as dessert fruits, are the product of E. malaccensis, E. aquea, E. jambos, and other species of this genus. In Brazil, the fruit of E. cratifora, the Jabuticaba, is also much esteemed. The leaves of E. Ugni are used in Chili as a substitute for Paragnay tas.

for Paragusy tea.

EULOGY, u'lloje (Gr. eu, well, and logos, a discourse), denotes, in a general sense, an encomium or panegyric pronounced on any one on account of his merits or virtue. By the early ecclesiastical writers, the term eulogy or eulogia was applied to the Eucharist; but it afterwards came to be restricted to the bread which was distributed among those who had not

communicated, or who were absent.

EULOPHIA, u-lo'-fe-d (Gr. eulophos, a handsome cret), in Bot, a gen. of Orchids. The tubercular roots of E. vera and E. cumpestris are much used in Iudia for the preparation of the nutritions substance known by the names of salep, salop, and saloop.

EUNUCH, w'-nuk (Gr. euns, a bed, and echein, to

EUNUCH, w'-nuk (Gr. euns, a bed, and echein, to have the care of), is literally, one who has the cure of a bed, a name given to this class of persons in the East, from their being intrusted with the care of the women's apartments, or harems. The practice is of great satiquity, and even in the time of Herodotus it was carried on to a great extent among the Persians, who not merely intrusted the care of their wives and daughter to expruse but considered them as more are most readily introduced when the apparatus is daughters to canuchs, but considered them as more arranged as shown in fig. 3, and the volume of trustworthy than other men. The practice of making aqueous vapour, formed after combustion, may easily be measured by replacing the current of cold water through the outer tube by a current of free steam. In this case it will be best to measure the gas under as court. Zeal for religion, as in he case of Origen, has

#### Engnymus

caused many persons thus to mutilate themselves; and in the 3rd century there arose a sect of heretics, who not only treated thus those of their own persuasion, but all others on whom they could lay hands. Several of the Christian emperors of Rome forbade the prac-tice of making eunuchs; and Justinian imposed a law tice of making ennuchs; and Justinian imposed a law of retaliation on such as were guilty of such inhumanity. The council of Nice, at a later period, excluded from the pale of the Church all who, from whatever cause, made ennuchs of themselves. The practice is said to have prevailed in Italy, with the view of preserving the voice of singers for the operas of Europe; and in the Rast, in the present day, the seraginos are chiefly guarded by eunchs.

BUONYMUS, 4-on-4-smus (Gr. eu, well; onoma, a name), in Bot., a gen. of the nat. ord. Celustracea. The species E. europæus is the common spindle-tree of our hedges. In France, charcoal prepared from the wood is largely used in the manufacture of gunpowder; while the young shoots, in a charred condition, are

while the young shoots, in a charred condition, are employed as rough crayons for sketching. The seeds are stated to be purgative and emetic, and also to be poisonous to sheep. The bark of *E. tingens* can be used as a yellow dye-stuff.

used as a yellow dye-stuff.

EUPATORIUM, w-pà-to'-re-um (derived by Linneus from Mithridates Eupator, who first used it as a counter-poison), in Bot., a gen. of the nat. ord. Composite, sub-ord. Tubiliflore. The leaves of E. quiti-nosum constitute a sort of matico, which is employed as a styptic. The matico used in this country is, however, derived from Artanthe elungata. E. ayapana and perfoliatum are employed as antidotes to the bites of venomous reputiles. of venomous reptiles.

ETHEMISM, u'.'fe.mism (Gr. eu, well, and phemi, I speak), is a figure in Rhet., by which one expression is substituted for another, so as to convey the meaning in less offensive or milder terms; as when we use the word departed for dead. Euphemisms were

word acparted for dead. Eupnemisms were much employed by the ancients to avoid the use of words or phrases which were regarded as ominous.

EUPNONE, "fo-ne (Gr. eu, well, and phone, sound), denotes an agreeable sound, or combination of sounds,—that pleasing quality in language which results from the happy combination of the enunciative elements.

EUPHORBIA, a-for-be-t (named after Euphorbus, physician to Juba, king of Mauritania), in Bot., the typical gen. of the nat. ord. Euphorbiacea, consisting of about 300 epecies, many of which have valuable properties. The acrid resin commonly known as gum Euphorbium is the produce of certain undetermined epecies, the principal of which are probably E. anti-quorum, cunariensis, and officinarum. It is a dangerous emetic, cathartic, and rubefacient, and produces severe inflammation of the nostrils if those who powder it do from the wounded stems, and collected in leather begs. In India it is said to be mixed with the oil expressed from the seeds of Sessamum orientale, and employed externally in rheumatic affections, and internally in cases of obstinate constipution. The Arabs are stated to make up violent diuretic pills by rubbing over the juice of the species E. antiquorum with flour : their camels, however, are said to est the branches of the plant when cooked. The juice of the species E. cerei formic, heptagona, and virosa, African plants, turnish the Ethiopians with a mortal poison for their arrows, whilst that of E. cotinifolia serves a like purpose for the Brazilian Indians. The species E. hibernica is exthe Brazilian Indians. The species E. kibernica is extensively used by the peasantry of Kerry for the purpose of stupefying fish; and so powerful are its properties said to be, that a small kreel or basket filled with the bruised herb suffices to stupefy the fish for several miles down a river. E. hypercifolia, a plant of tropical America, is astringent and somewhat narcotic, and is employed in the diarrhos of children and as a vermifuge; and E. thymifolia is employed for a like purpose in India. The root of E. Ipecacuanha is and to be equal to the true ipecacuanha, and is com-monly used in the states of North America. Another member species, E. corolata, the milk-weed, is also used as an emetic in the States. The fruits of E. lathyris, or experience, are sometimes pickled and eaten, instead of ordinary capers; but although the process of pickling appears to destroy in a great measure the acrid purgative properties which the fruits possess in a fresh

# Eutychians

state, their use is by no means free from danger. A very active cathactic oil may be expressed from the seeds of the caper-spurge. The leaves of E. sergible are prescribed by the native practitioners of India-bath internally as a purge, and externally, mixed with Margosa oil, in certain cases of contracted limb. The roots of E. palustris and pilosa are used as purgatives, and are said to have proved useful in hydrophobia. Many other species are purgative. E. Tirucalli, a native of India, is common in the Madras presidency, and makes an excellent hedge, as no cattle will touch its leaves. The sap of E. phosphorea is said to aline with a phosphorescent light in the forests of Brazil on warm nights.

nights.

EUPHORBIACE, u-for-be-ai'-se-e, in Bot., the Spurgewort fam., a nat. ord. of Dicotyledones, in the sub-class Monochamydes, consisting of trees, shrubs, and herbaceous plants, generally with an aerid milky juice. The flowers are uniexual, monocious or diceious, terminal sematimes inclosed in a calyx-like axillary or terminal, sometimes inclosed in a calyx-like involucre; achlamydeous, or with a lobed inferior calyx, having on its inside glandular or scaly appendages, or even evident petals, which are either distinct or united. The anthers are two-celled. The female flowers have a superior ovary, which is either elevated upon a stalk or sessile upon the thalamus, one-, two-, three-, or many-celled. The styles are either absent, or corresponding in number to the cells of the overy, entire or divided. The stigmas are equal in number to the cells of the overy, or, when the styles are divided, corresponding in number to their divisions; the ovules, one or two in each cell, suspended from the inner angles of the cell. The fruit is either dry, when its parts separate from each other and from the axis, its parts separate from each other and from the axis, usually opening with elasticity, or succulent and inchiscent. Seeds one or two in each cell, suspended, often with an aril or carunculate. Embryo inclosed in fleshy albumen, cotyledons flat, radicle superior. The plants of the order are more or less distributed over the globe, but are especially abundant in warm regions, particularly in equinoctial America. Many are extremely poisonous, the poisonous principle being contained in the milky juice, and pervading all parts of the plant, more or less. Many have been employed medicinally, as rubefacients, suppurants, emetics, and cathartics. Some, as cascarilla, are toffic, aromatic, and stimulant, and are perfectly devoid of any aerid or poisonous principle. Others, as manihot, yield starch, which is largely employed for food. Cacutchous and resin are obtained from the milky juice of others. The seeds of many yield oils, milky juice of others. The seeds of many yield oils, either of a bland or of an irritating nature. A few of the fruits, and some of the roots, are said to be eatable. Timber is yielded by some, as the box; and dye-stuffs by others. The hairs of some are stinging.

RUPHUISM, ul-fu-izm (Gr. suphues, eloquent, of vigorous growth), a word employed in English literature to designate a bombastic inflated mode of expression. This style of language enjoyed a short-lived popularity during the reign of Elizabeth. The term originated from the title of a book by John Lyly, "Kuphues," whose affected language formed the model of the

style.

EUTION, w'-pe-on (Gr., very fat).—A very limpid fluid, first discovered by Reichenbach in wood tar. It is found in the tar produced by the destructive dis-tillation of several vegetable and snimal substances, its properties being found to agree with those hydrone properties being found to agree with those hydro-carbons found in Boghead mineral. It evaporates at 340°; its specific gravity is 0.74. It is soluble in alcohol and ether, but does not dissolve in water. It has no smell, is tasteless, and is highly inflammable. It is the opinion of Mr. C. Greville Williams that this and other hydrogenican will acceptable by a format and other hydrocarbons will eventually be of great value in the arts.

value in the arts.

EUSTACHIAN TUBE, in Anat. (See EAR.)

EUSTACHIAN VALVE, u-stat'-ke-da (after Eustachius, the celebrated anatomist), in Anat., is a membranous semiliner valve separating the right auricle of the heart from the inferior veus cava.

EUTERPE, u-ter-pe, in Rot., a gen. of palms. The species E. montana is one of the cabbage-palms, so called because the joung leaf-buds are boiled and eaten like cabbage. eaten like cabbage.

EUTECHIANS, u-tik'-e-dus, in Recl. Hist., were a re-

### Evangelical

bigious sect which arose about the middle of the 5th century, and were named after their founder, Buty-ches, abbot of a monastery in Constantinople. In opence, apper or a monastery in constanting. It op-posing the doctrines of Nestoring who had been charged with dividing the nature of Christ into two distinct per-sens, they fell into the opposite extreme, and held that the human nature of Christ was absorbed in the divine, and that his body had no real existence. Their views were condemned in a synod held at Constantinople in 460, by Flavian, patriarch of that city, and Entyches himself deposed; but the following year this judgment was reversed by a general council held at Ephesus, and the doctrine of Eutyches declared to be orthodox. Butychianism, however, was finally condemned in 451, at the general council of Chalcedon, which de-clared "that in Christ two distinct natures were united in one person, and that without any change, mixture, or confusion." The heresy, however, spread very extensively through the East, and the monophysite doctrine continues to exist in the Armenian and Coptic churches to the present day.

Brangenical, e-van-jel-e-kal (from Gr. enaggelion, good news), denotes, in general, agreeable to, or in conformity with, the doctrines of the Gospel. It is frequently applied to those who make the actonement of Christ alone, and not the performance of moral duties, the ground of salvation; and hence it is frequently used as synonymous with orthodox. A body in the Anglican church assume to themselves the name of Evangelical, their views coinciding very much with those of dissenters. In Prusia the term is employed to designate the national Protestant church, which is formed by a union of both Calvinists and Lutherans.

being an attempt to unite the two parties.

EVANGELICAL ALLIANCE is an association of Christians of various denominations, formally organized in London in 1846. Its object is to promote unity and co-operation among the different sects of Protestants, and to unite their efforts against the advances of Ro-manism and infidelity. Their object is also to encou-rage and strengthen labourers in the cause of Christisuity in all parts of the world, particularly such as are struggling with difficulties and hardships. They also exert themselves in behalf of religious toleration in all parts of the world. They have numerous branches, not only in the United Kingdom, but France, Germany, Sweden, and other parts of the contineut; America, Australia, East and West Indies, Africa, &c. The members of the alliance are such as hold evan-The members of the alliance are such as hold evan-gelical views on the following points:—the divine in-spiration of the Holy Scriptures, and the right of private judgment; the Trinity; depravity of human nature; the incarnation; justification by faith alone; the work of the Holy Spirit in conversion; the immor-tality of the soul; resurrection and judgment; the divine institution of the Christian ministry; and the obligation of the ordinauces of baptism and the Lord's sunner. They hold conferences for devotion and supper. They hold conferences for devotion and mutual consultation in London, Paris, Berlin, and other cities; the last being held at Geneva, in 1861.

EVANGELICAL ASSOCIATION, a religious body which took its rise in the state of Pennsylvania in 1800, and has since spread over most of the free states and a great part of Canada. Its founder was Jacob Albrecht. a German Lutheran, who, impressed with the want of religious life and the corruptions that prevailed among the German churches, commenced a course of ikinerant preaching, and made many followers. In 1859 they had over 300 itinerant, and a still greater number of local preachers, while their adult members were nearly 40,000. They devote themselves much to missionary labour, especially among the German pulation. In theology, they are Arminian; but on her points they agree in the essentials of Christianity population. with the various evangelical churches, with whom they

seek to cultivate friendly feelings.

Evangelical Union, the name assumed by a re-ligious body which was formed in Scotland in 1843. ligious body which was formed in Scotland in 1845, but which are better known under the name of Morrisonians. Their founder, the Rev. James Morrison, of Kilmarnock, was ejected from the United Secession Church for holding views contrary to the standards of that body. He held that the death of Christ bore no special relation to the elect, but was for the sine of the whole world; that all men were able of themselves to

#### Eviction

believe the Gospel; that original ain cannot render believe the Gospel; that original sin cannot render men liable to condemnation; that no person ought to be directed to pray for grace to help him to believe. EVARGELIET, e-cin'-je-list (Gr. es., well, and aggello, I announce), is properly one who brings good tidings. Hence the writers of the four gospels are called evan-gelists, because they proclaim the glad tidings of salvation through Christ. Evangelist was also the name given to a particular class of Christian teachers chosen by the spostles to preach the Gospel, and asking effect the anostles and prophets but hefore chosen by the apostles to preach the Gospel, and ranking after the apostles and prophets, but before the pastors and teachers. They had no particular flocks assigned to them, but travelled from place to place under the direction of the apostles. This order is supposed to have been merely temporary, like that of apostles and prophets; and the term is now only applied to those writers in the New Testament who

have given us the history of our Lord.

EVAPORATION, e-vap-o-vai'-shun (Lat. evaporatio, an evaporation), the conversion of liquid or solid bodies into elastic vapours or gases by means of heat. Evaproration goes on allowly or rapidly according to cir-cumatances. Water evaporates gradually at ordinary temperatures all over the surface of the globe. It rises in the air as vapour, and when condensed by change of temperature, forms rain or dew, and de-scends again to the earth. When, however, evapo-ration takes place rapidly, as in the case of ebullition, it is generally called vaporization. The quantity of vapour which rises from the surface of a liquid in the open air not only depends upon the quantity of surface exposed, but also on the state of the atmosphere lace exposed, but also on the state of the atmosphere at the time. In warm and dry weather, both in winter and summer, evaporation is greatest. It was found by Dr. Dalton that water raised to 212° evaporated at the rate of 4248 grains per minute. Mercury does not evaporate till it is raised to 60° or 80°. Below that temperature the gravity of the constituent atoms is greater than their clastic force. In all liquids whose boiling-points are high, the clastic force of the vapour is very small. The clastic forces of the vapours of most solid bodies are so low that they cannot be evaporated by the highest natural temperatures. evaporated by the highest natural temperatures. The evaporation of a liquid is a gooling process to the liquid itself. This fact is made useful in India in order to produce ice. Water is exposed in shallow, unglazed, earthen vessels, resting upon imperfectly conducting substances, such as sugarcanes, &c. During the dry clear nights evaporation goes on, and a thin film of ice is formed. The cold produced by the formation of vapour may easily be observed by placing a cloth dipped in ether or alcohol on the bulb of a thermometer. The mercury will continue to deseen as long as the evaporation lasts. If mercury is placed in the receiver of an air-pump, together with placed in the receiver of an air-pump, together with sulphuret of carbon, when the air is withdrawn, the cold produced by the cyaporation of the sulphuret of carbon is sufficient to freeze the mercury. (See METEOROLOGY, HYGROMETER, RAIN.)

Eve, ew (Aug. Sax.), is a term frequently applied to the night before certain holidays or festivals; as Christmas eve, the evening before Christmas day. In the primitive church, it was customary for Christians to pass a great portion of the night which preceded a holiday in religious exercises; and these, from their being performed in the night-time, were called vigils

or watchings. These night meetings came to be so much abused that they were at length abolished. Evening Schools. (See Schools.) Evening Schools. (See Schools) even restricted of a hip on the water; thus, a ship is said to swim upon an even-keel when she draws the same draught of

water forward as abaft.

EVICTION, e-vik'-shun (from Lat. evince, I over-come), signifies a recovery of lands by means of a form of law. It is, however, one of the most severe processes, and it is only resorted to in extreme cases. To render an illustration, it may be stated that it has been, at various times, called into action in Ireland, peen, as various times, called into action in Ireland, where tenants were evicted, i.e. driven off the lands they rented, in consequence either of inability or unwillingness to pay their rent, or, as in late instances, on account of the prevalence of Bibboursm or landlord murder. With regard to its legal properties, it is recorded, that if land is evicted before the time of

804

#### Evidence

payment, the said land being on lease, no rent is incurred or is liable by the lease. Where lands are taken "on extent," and are evicted or recovered by better title, the plaintiff shall have a new exceution If a widow is evicted of her dower or thirds, she shall be endowed with the other lands of the heir. Lastly, if in exchange of lands, either party is evicted of the lands given in exchange, he may enter again into possession of his own lands which he thus exchanged. (Not further information, see Law Reports.)

(For further information, see Law Reports.)

EVIDENCE, eve-e-dens (Ang.-Nor., from Lat. evidentia), in Law, denotes, in its widest sense, whatever, exclusive of mere argument, legally tends to prove or disprove any matter of fact, the truth of which is sub-mitted to judicial investigation. It is so called because mitted to junious invessigation.

It makes evident or clear, or saccrtains the truth of the fact or point at issue, either on the one side or on the other. When such evidence is sufficient to produce a continuous control of the con conviction of the truth of the fact to be established, it amounts to proof. By competent evidence is meant that which the law requires as the fit and appropriate of a writing where its contents are the subject of inquiry. By satisfactory evidence, or, as it is sometimes called, sufficient evidence, is denoted that amount of proof which ordinarily satisfies an unprejudiced mind beyond reasonable doubt. Circumstantial ovidence is denoted that amount of proof which ordinarily satisfies an unprejudiced mind beyond reasonable doubt. Circumstantial ovidence is denoted that amount of the content of the dence is distinguished from positive proof, and is founded on the doctrine of presumptions; for when the fact itself cannot he demonstratively evinced, that which comes nearest to the proof of the fact is the proof of such circumstances as necessarily or usually proof of such circumstances as necessarily or usually attend such facts. Very strong presumption is, in many cases, equal to full proof. As a general rule, the best evidence of a fact must be given that its nature admits of. This rule does not demand the greatest amount of evidence which can possibly be given of any fact, but is to prevent fraud; the presumption being, when the best evidence is withheld, that the party has some sinister motive for not producing it. Primary evidence is that kind of proof which in the eye of the law affords the createst certainty of the the eye of the law affords the greatest certainty of the fact in question. All evidence falling short of this in its degree is termed secondary. This distinction in its degree is termed secondary. This distinction refers only to the quality, not to the strength of the proof; for evidence which carries on its face an indication that better remains behind, is not primary but se-condary. As a rule, secondary evidence is inadmissible until it be shown that the production of primary evidence is out of the parfy spower; as where an instrument is destroyed or lost, its contents may be proved by secondary evidence. The first degree of evidence, and, though liable to error and misconception, the most satisfactory to the mind, is that afforded by the senses; as where a judge or jury can have the matter in dispute brought before their eyes, so that they may judge for themselves. This mode of evidence, however, is seldom attainable in judicial trials, and the law is satisfied with requiring the next bestevidence,—namely, the testimony of those who can speak from their own personal knowledge, which is termed heavay evidence. But it is requisite that, whatever facts the witness may speak to, he should be confined to those lying within his own knowledge, whether they be things said or until it be shown that the production of primary evihis own knowledge, whether they be things said or done, and should not testify from information given by others, however worthy of credit they may be. The dying declaration of a person who expects to die, respecting the circumstances under which he received a mortal injury, is admitted as evidence in criminal prosecutions in regard to the death, though the accused secutions in regard to the death, though the accused; was not present when they were made, and had no opportunity for cross-examination; it being considered that a person in constant expectation of immediate it to the temporal from all temptation to falsehoods; but it is necessary to show that he was aware of his condition at the time of making his declaration. A person is said to be admitted as queen's evidence when, being one of the accused, he confesses his crime, and is admitted as evidence against his accomplies. It is

Examination

antithesis or negation of good. "In the abstract, evil is want of conformity to the standard of good, whatever that may be; in the concrete, evil is snything that comes short of what is perfectly good." A very superficial view of things as they exist in this world is suffiiciat view of taings as they exist in this word is sumi-cient to convince one of the existence of evil; i. e. that all things come short of our ideal of goodness and per-fection. Evil is usually divided into physical and moral, —the former including whatever is opposed to good in the sense of happiness; the latter, whatever is opposed to good in the sense of virtue. The question concerning the origin of evil has exercised the ingenuity of speculative men from the earliest times, and various speculative men from the earliest times, and various theories have been proposed. The oldest and most widely spread of these is the *dualistic*, which supposes two opposite agencies or co-eternal and independent principles, the one the author of all the good, the other of all the evil in the universe. This doctrine prevails in the heathen systems of the East, and was also held by the Manichmans and others. A favourite hypothesis among the ancient philosophers was that of pre-existence; according to which, the evils which we suffer at present are punishments and expiations of moral delinquencies committed in a former stage of moral delinquencies committed in a former stage of our being. The doctrine of optimism supposes that all events are ordered for the best, and that the evils which we suffer are parts of a great system conducted by almighty power under the direction of infinite wisdom and goodness. This comprises two very dif-ferent classes of philosophers,—those who admit and those who deny the freedom of human actions and the accountableness of man as a moral agent. None of these modes of solving the difficulty appears satisfac-tory, and the Bible throws little light upon the subject. "The Bible, however, fully authorizes the only con-clusions to which reason can safely come on this dark clusions to which reason can safely come on this dark subject; viz.—1. That God is not the author of evil in any sense; 2. that, though able to prevent it, he has permitted it to exist; 3. that the evil permitted in the universe is not only less than the good directly willed by God, but is characterized as something intrusive and transitory, while the good is fundamental and permanent; 4. that God, in permitting evil, has not left it uncontrolled, but even holds it in his power and makes it subservient to his purposes; 5. that he will pltimately overrule the evil which he has permitted, so as to evolve a larger amount of good for his universe than if evil had not been permitted; and, in fine, that all that is perplexing to us in the existence of evil arises out of the limitation of our understanding;" that "the phenomenon of evil, which to us is so full of difficulty, may by higher intelligences—must by the highest—be may by higher intelligences—must by the highest—be seen to be in perfect accordance with the noblest order and the purest rectitude."—(Alexander.)—Ref. Ency-clopadia Britannica, art. "Evil." by Dr. W. L. Alex-ander; Stewart's Philosophy of the Active and Morad Powers; King, On the Origin of Evil; Müller, On the

Christian Doctrine of Sin.

Evil Eve, a malignant influence superstitionsly secribed to certain persons, in virtue of which they are supposed to injure those on whom they cast an envious

or hostile look.

EVIL, KING's, a name formerly applied in England to scrofula, from the belief that it was curable by the touch of the king. This belief was long and very generally held, and we are told that Dr. Johnson was touched

for this disease.

EWR, the female of the sheep. (See SEREP.)

EXAMINATION, egs-am-in-ai-shun (Lat. examinatio), is the usual mode of ascertaining the nature and extent of one's attainments. Examinations are of three kinds, advantional competitive, testing. The first of these -educational, competitive, testing. The first of these is employed in teaching, the second is resorted to for is employed in teaching, the second is resorted to for ascertaining the relative merits of several individuals, and the last determines who ome up to a fixed standard. In teaching, standard means of training the faculties of the scholar; tending mot only to fix his knowledge of the scholar; tending mot only to fix his knowledge in his mind, but to give him a proper command of it, and a facility in using it, that he would not otherwise statim. It is necessary that these objects be kept distinctly in view by the teacher, otherwise he may be the means of unsenting rather than establishing the is admitted as evidence against his accomplices. It is, in his mind, but to give him a proper command of it, at the discretion of the court whether they admit one and a facility in using it, that he would not otherwise as queen's evidence; but if he is admitted, and his attain. It is necessary that these objects be kept dispartners are convicted, he is entitled to his pardon.—

\*\*Edge Taylor's Treatise on the Law of Evidence; the means of masseting rather than establishing the scholar's knowledge, and may give confusion rather Evil., e'-vi (Sax. efel, yiel), may be said to be the than clearness to his ideas. Competitive examinations

are such as are made of a number of individuals for the purpose of determining their relative attainments, and are more especially with the view of bestowing prises. Competitive examinations are very liable to abuse, and ought to be used with caution, as their tea-deucy is to stimulate emulation, rather than foster a love of learning for its own sake; to exercise the memory, rather than to train the other faculties; and memory, rather than to train the other faculties; and to make all the reading and thought of the caudidates turn upon the examinations. It also gives rise to a system of "cramming," by which many things are committed to the memory that should never have been thrust upon it, and which are not intended to be retained. All this is very injurious to the natural powers of the mind. In test or pass examinations, the object is not to assertain the relative qualifications of a number of candidates, or their highest attainments, but who of them come up to a certain standard. They are used to determine the shilty of a candidates. They are used to determine the ability of a candidate to enter a university or to join a particular class, to be admitted to practise a certain profession, or to fill a particular folice. Test examinations, if properly conducted, if the subjects of examination are judiciously selected, and if the standard is properly adjusted, are of great value and importance. Examinations may be conducted either orally or by writing, and each has its particular advantages; so that the best is a judicious combination of the two. In an oral examination, the examiner can most easily and clearly discover the depth of the scholar's attainments, and ascertain his readiness, and the command that he has over what he Too much stress, however, ought not to be laid upon this kind of examination; for there are some persons whom it renders nervous and incapacitates from sous whom it removes nervous and incapacitates from using their knowledge. There is also a class of persons known as the "slow but sure," who are not calculated to shine in this way. By written examination, the defects of the oral may be compensated. Subjects that require deliberation, and which are intended to test the reaching normal and individual to the contract of the compensation of the compensati soning powers and judgment, are best treated in this way. The subject of examinations has recently come way. The subject of examinations has recently come to acquire greater importance, from their being now used in determining the qualifications of candidates for the civil service (which see). Much has been said both for and against this measure; and there can be no doubt it has its good and its bad features. It is however, a decided improvement upon the previous extension and many of its objectionable features are system; and many of its objectionable features are such as will necessarily disappear in time, and as the subject comes to be better understood. One danger is the laying too much stress upon the examinations; for, however useful they may be in ascertaining special acquirements, they, in general, afford little means of judging of the more important qualities of industry, punctuality, steadiness, attention. Every-day experience shows that men have risen to the highest rank in their several walks of life who were never remarkable for their acquirements at school. In general, the standard of examination is placed too high, and embraces too great a variety of subjects,—subjects, too, which have little or no bearing upon the office which the cand date is intended to fill. Government, in this respect, might well look to the proceedings of private individuals. A merchant scarcely requires of his clerk to be well read in the ancient classics, or "up" in the be be well read in the ament classics, or "up" in the higher mathematics; or of his messenger to be well versed in history and geography. The present system, however, is immeasurably in advance of the old; and we may reasonably hope that many of its present defects will be remedied in the course of time.

defects will be remedied in the course of time.

EXCELLENCY, ek'-sel-len-se (Lat. excellentia, excellence), a title first borne by the Lombard kings, and afterwards assumed by several emperors of the West.

It was afterwards transferred to the inferior princes, especially in Italy, until they also gave it up, after Pope Urban VIII., in 1630, had bestowed the title of "eminence" on the cardinals. Since that period the title of excellency has become a title of office or service, neither hereditary nor transferable from one member of a family to another. but always belonging service, neither hereditary nor transtration from one member of a family to suother, but always belonging to the office. In Europe it is only borne by ministers in actual service, by the highest court and military digutices and, by ambassadors and openipotentiaries, Governors of English colonies also receive the title

of excellency.

EXCHANGE, eks'-tshainj (Fr. échange), is, properly, the giving of one thing or commodity for another, and in commercial language is employed to denote the means by which the debts of persons residing at a means by which the debts of persons residing at a distance from their creditors are discharged without the transmission of money or goods. This is effected by means of what are known as bills of exchange. A bill of exchange is simply an order addressed to some person at a distance, directing him to pay a certain specified sum to the person in whose favour the bill is drawn, or his order. A merchant in London, who may have the content of he due a sum of money for goods to a merchant in be due a sum of money for goods to a inerchaft in Hamburg (instead of remitting money or goods to the amount of the debt), goes into the market and buys from another merchant who has a debtur in Hamburg a bill of exchange for the amount, which he transmits to his creditor in Hamburg, who in this way gets pay-ment of his debt from a person in his own town, the debtur of the second merchant. In this way, the debtor in the one place is substituted for the debtor in the other, to the great convenience of all parties. Bills of in the one piace is substituted for the debtor in the other, to the great convenience of all parties. Bills of exchange are of two kinds,—inland and foreign; inland, when both parties are in England; and foreign, when one of them is abroad, or in Scotland or Ireland. (See BILL OF EXCHANGE.) Exchanges between different parts of the United Kingdom are now almost entirely in the hands of handers. In often or sounding hands of the control of in the bands of bankers. In cities or countries having a considerable amount of intercourse together, the debts mutually due by the one to the other approach for the most part near to an equality. Between countries making use of different currencies there is what is known as a par of exchange, which is the equivalency of a certain amount of the currency of one country in the currency of the other, the currencies of both being supposed to be of the precise weight and purity fixed by their respective mints. Among the causes that affect the par of exchange, in addition to a rise or fail in the price of the precious metals, are, (1) changes made by authority in the quantity of pure metal con-tained in the coin by way of increase or diminution; tained in the coin by way of increase or diminution; (2) depreciation from the use of paper-money; (3) dipping; (4) tear and wear. When two countries trade together, and each boys of the other exactly to the amount that it sells, their claims will balance each other, and the exchange will be at par. This, however, is rarely the case; for there is almost always a balance owing on the one side or the other, and this balance affects the rate of exchange. Thus, if London sends more goods to Hautburg than she receives from it, there will be a greater demand for bills upon London in Hamburg than of bills upon Hamburg in London, and their value will proportionally advance above par, while in London, in like manner, they will fall below it. It is evident, however, that these fluctuations in the real exchange are subject to certain limits, beyond real exchange are subject to certain limits, beyond which they cannot advance. Thus the price of bills of exchange on any place can never exceed the expense of sending bullion to that place, otherwise the merchant will find it to his advantage to transmit bullion in place of bills. The tendency of any advance in the rate of exchange is to stimulate exportation and to put a check upon importation.—Ref. Encyclopadia Britannica, art. "Exchange." by J. R. McCulloch; McCulloch's Com-

mercial Dictionary.

Excheques, eks-tshek-ker (Ir. échiquier, Lat. scaccarium), is the name of an ancient court of record, wherein all causes touching the revenue and rights of the crown are heard and determined, and where the revenues of the crown are received. According to Camden, the court took its name from the chequed count, resembling a chess-board, which covered the table there, and on which, when certain of the king's accounts were made up, the sums were marked and scored with counters. This court was established by William the Conqueror as part of the Aula Regis, and reduced to its present order by Edward I. It was principally intended at first to order the revenues of the crown and to recover the king's debts and duties; but it subsequently acquired the additional character of an ordinary court of justice between subject and subject. It consists of two divisions,—the receipt of the exchequer, which manages the royal revenue, and the court, or judicial part of it. (See Court or Ex-CHEQUER.) As a court of revenue it ascertains and enforces, by proceedings appropriate to the case, the

preprietary rights of the crown against the subjects of the realm. To proceed against a person in this depart-ment of the court is called to suckequer him. The practice and procedure on this side of the court was amended by 22 & 23 Vict. c. 21. The judges of the court of Exchequer are the chancellor of the exchequer and one chief and four other barons. The first of these, however, now exercises no judicial functions, and only takes his seat formally on certain occasions. The duties of the chancellor of the exchequer are confined to matters relating to the finance of the country and the receipt and payment of revenue. He is, in fact, the principal finance minister of the crown, and exercises the chief and most responsible control over the expenditure of the different branches of the public service, the details of which are annually submitted for his rethe details of which are annually submitted for his re-vision. He prepares the annual statement of the esti-mated expenses of the country, and the ways and means by which they are to be defrayed, including the im-position or remission of taxes. (See Burger.) This office has sometime: been held conjointly with that of

office has sometimer been held conjointly with that of tirst lord of the Treasury.

Exchequer Bills are bills of credit issued under authority of parliament, and forming the principal part of the unfunded debt of this country. They are for sums varying from £100 to £1,000, and bear interest generally from ½d. to ½d. per day per cent., according to the usual rate of interest at the time. They were first issued in the reign of William III., 1696, and have been continued annually ever since. The amount of exchequer bills outstanding and unprovided for in 1861 was £20,435,107. The bills pass from hand to hand as money without any formal transfer, and the option is given periodically to holders of being paid their amount at par. Act 24 Vict. c. 5 (1861), declares that fourteen days prior to the expiry of each twelve months from the date of issue, and during their legal currency, notice is to be given in the London Gazette, that payment will be made, and if not then claimed, such bills are to have legal currency for another twelve months, and go on from year to year; but the holder cannot claim payment at any interval between the times fixed by such yearly notices; ex-cept that such bills during any part of the last six mouths of each year may be used in payment of any duties or taxes due to the crown. It is enacted that the bills are to be prepared in a form fixed by the Treasury, and to be signed by the comptroller general or assistant comptroller, the rate of interest being fixed by the commissioners of the Treasury, and to be payable half-yearly by the Bank of England, but not to exceed £5. 10s, per cent, per annum. The Treasury are empowered to issue new bills to replace old ones to any amount not exceeding £13,230,000.

EXCHEQUER, COURT OF. (See COURT OF EX-

CHEQUEE.)

EXCISE, eks-size' (Du. accys, Ger. accise), is derived from the Latin excisa (see. pars), and properly signifies that part of the profits of the manufacturer or producer which is out off for the support of the government, before the commodity is sold. It is generally applied to those taxes or duties which are levied upon certain articles produced and consumed at home,—excissable articles when exported to other countries being usually entitled to a certain drawback. There are, however, certain duties included in the excise branch of the revenue to which the above defiexcess oranne of the revenue to which the above demision does not strictly apply; as licenses for carrying or certain trades. This mode of taxation had been established in Holland at an early period, but was first introduced into this country by the Parliament in 1643, in order to carry on the war against the Crown. The royalists soon after also had recourse to this mode of revaluts soon after also had recourse to this mode of raising money, both sides declaving that the excise should be continued no longer than to the end of the war. It was first imposed upon the makers and vendors of beer, ale, cider, and perry; but the Parliament soon after laid it on flesh, wine, tobacco, sugar, and a number of other commodities, in pursuance of a plan

been accustomed to it for some years, the Parliament openly declared, in 1649, that "the impost of excise was the most easy and indifferent levy that could be laid upon the people;" and, accordingly, it was con-tinued during the Commonwealth. Upon the Restora-tion, the excise duties were by 12 Car. II. c. 24, granted as part of the revenues of the crown, in lieu of the military tenures and the right of pre-emption of the inhitary tenures and the right of pre-emption and purveyance. By 30 Geo. II. c. 19, this branch of the royal revenue was taken from the crown and an annual sum of upwards of \$27,000 granted in its stead. During the reigns of William III. and succeeding monarchs, excise duties were laid upon a number of commodities in order to meet the enormous expenditure. commodities in order to meet the enormous expenditure occasioned by our wars on the continent. "Thus," says Blackstone in 1765, "brandles and other spirits are now excised at the distillery; printed silks and linens at the printer's; starch and listing powders at the maker's; gold and silver wire at the wire-drawer's; plate in the hands of the vendor, who pays yearly for a license to sell it; lands and goods sold by anction, for which a pound-rate is payable by the auctioneer, who also is charged with an annual duty for his license; and coaches and other wheel-carriages, for which the occupier is excised, though not with the same circumstances of arbitrary strictness as with the same circumstances of arbitrary strictness a in most of the other instances. To these we may add in most of the other instances. To these we may add coffee and tea, chocolate and cooo-paste, for which the duty is paid by the retailer; all artifloial wines, commonly called sweets; paper and pasteboard, first when made, and again if stained or printed; malt, as before mentioned; vinegars; and the manufacture of glass, for all of which the duty is paid by the manufacturer; hops, for which the person that gathers them is answerable; candles and soap, which are paid for at the maker's; malt liquors brewed for sale, which are excised at the brewery; eider and perry at the vendor's, and leather and skins eider and perry at the vendor's, and leather and skins at the tenner's." It is unnecessary to enter at length upon the numerous alterations that have from time to time been made in this branch of the revenue. The malt duty was first imposed in 1695. In 1797 the number of exciseable articles was twenty-seven; in 1833 they were reduced to fifteen; and in 1837 to nine, either by the duty being totally repealed or by being trausferred to the management of some other department, by which it might be collected with greater economy and convenience. In 1823 the separate and independent boards of excise for England, Scotland, and Ireland, were conjoined; and in 1849 the excise was united with the stamps and taxes under one board, consisting of a chairman deputy-chairman, and four other commissioners, entitled the Commissioners of Inland Revenue. These have full power to make all necessary rules and regulations, to enforce payments, and to appoint collectors and other subordinate officers. dinate officers, subject always to the control and in-structions of the lords of the Treasury. To facilitate the collection of this branch of the revenue the United the collection of this branch of the revenue the United Kingdom is divided into collections; of which there are fifty-five in England and Wales, thirteen in Scotland, and fifteen in Ireland. Each collection is divided into several districts, and each district is subdivided into rides and footsalks. A ride comprises a considerable tract of country, in which the traders are thinly scattered, and the surveying officer is required to keen a boxes. In towns where the traders subject to keep a horse. In towns, where the traders subject to survey are within a small circuit, the district under one officer is termed a footwalk or division. These survey officers are obliged to keep a minute account of each survey and of every particular connected with it the exact time it commenced, how long it continued, &c. Each district is under the charge of a supervisor, who has thus the superintendence of a certain numshould be continued no longer than to the end of the war. It was first imposed upon the makers and vendors of beer, ale, cider, and perry; but the Parliament soon after laid it on flesh, wine, tobacco, sugar, and a number of other commodities, in pursuance of a plan proposed by Pym, who is considered to have been the inther of the excise; and who, in a letter to Sir John Hotham, easy that they had proceeded in the excise to many particulars, and intended to go on further; but that it would be necessary to use the people to it by checks by surveying after them at uncertain times, examining their accounts, and keeping a diary, in which he inserts the particulars of his own surveys, and the errors which he may have discovered in those of the officers. The chief officer of each collection is termed a collector. He examines the diaries kept by the supervisors, and collects the duties payable in his district. The collector thus surveys the protection is termed a collector thus surveys the protection is district. The collector thus surveys the protection is termed a collector. He examines the diaries kept by the supervisors, and collects the duties payable in his district. The collector thus surveys the protection is termed a collector. He examines the diaries kept by the supervisors, and collects the duties payable in his district. The collector thus surveys the protection is termed a collector. He examines the diaries kept by the supervisors, and collects the duties payable in his district. The collector thus surveys the protection is termed a collector. He examines the diaries kept by the supervisors, and collector thus surveys and the errors which he may have discovered in those of the officers. ber of ride and footwalk officers, whose proceedings

of the system which Mr. Pitt in 1787 pointed at as a model for other public departments, on account of its efficiency and good management. There are also cer-tain classes of officers below the ordinary surveying tain classes of officers below the ordinary surveying officers,—assistants, supernumeraries, and expectants. The traders subject to survey may be divided into four classes:—(1) those visited for the purpose of charging growing duties, as maltsters; (2) those whose license is high or low, according to the extent of their consumption, as brewers and tobacco manufacturers; (3) those subject to a license for dealing in articles upon which excise duty has, or ought to have been paid, as innkeepers; and (4) those subject to a license for dealing in articles on which customs been paid, as innkeepers; and (4) those subject to a license for dealing in articles on which customs duty has, or ought to have been, paid; as dealers in tes or tobacco. The excise was introduced into this country at a time when the attention of the state was directed to the readiest means of raising money, without much regard to its effects upon industry, or the general welfars of the people; and hence a strong prejudice long existed against it, which has not yet quite died out. Dr. Johnson defined it to be "a hateful tax levied upon commodities, and adjudged not by the common judges of property, but by wretches hired common judges of property, but by wretches hired by those to whom the tax is paid;" and Blackstone says that "from its first introduction to the present time its very name has been odious to the people of England." Among the objections to the present excise England. Among the objections to the present excise system, is its interference in many cases with the freedom of the manufacturer in his operations. The officers inspect and control his premises and machinery, take cognizance of every part of the process, and often prescribe the mode of conducting and the time of commencing and completing each operation. It is said that upon the same premises, with the same capital, and the same amount of labour, double the quantity of cloths have been printed that could have been done previous to the repeal of the duty and the consequent removal of ex-cise restrictions; and the duty on glass was avow-edly repealed in order to facilitate improvements in its manufacture. A London distiller stated to the Commissioners of Excise Inquiry, some years ago, that, Commissioners of Excise Inquiry, some years ago, that, assuming that the duties on spirits distilled by him should be fully secured to the revenue, "it would be well worth his while to pay £3,000 a year for the privilege of exemption from excise interferente."

Dr. Ure, in the article "Brewing," in his Dictionary, says,—"As usual, the excise regulations interfere nuch with the progress of this, as of every other manufacwith the progress of this, as of every other manufacwith the progress of this, as of every other manufac-ture under fiscal superintendence. Careful to prevent fraud, they cripple industry, and seek, as it were, to secure the honesty of the labourer by cutting off his hand; ignorant or careless, meanwhile, of the perma-nent mischief which they inflict." Another objection to the present system is the inducement that the high duties, in certain cases, hold out to fraud. The higher the duties, the greater will always be the temptation to defraud the revenue; and all attempts to keep down to defrand the revenue; and an attempts to keep down smuggling, and at the same time maintain high duties, have signally failed. High duties, says Adam Smith, "tempt persons to violate the laws of their country, who are frequently incapable of violating those of natural justice, and who would have been in every respect excellent citizens, had not the laws of their country made that a crime which nature nover meant to be so." These objections can only be removed by country made that a crime which nature never meant to be so." These objections can only be removed by lowering the high duties, and, if necessary, including a greater number of articles. Duties within reasonable limits are uniformly found to be more productive than higher duties, which diminish the demand for the commodity and give encouragement to snuggling. Were light duties the posed upon a number of articles, instead of, as at present, heavy duties on a few, wars of the present restrictions might be removed. many of the present restrictions might be removed many of the present restrictions might be removed; and we believe that a greater sum might thus be raised, with little or no additional expense in collecting. The inducements to fraud would thus, in a great measure, be removed, and more might, with advantage, be trusted to the honour of the manufacturer. Experience also shows that the repeal or reduction of moderate duties, provided they have not interfered with the operations of the manufacturer, does not in a proportional degree render those articles cheaper to the consumers. Again, the excise laws, though in this respect they 808

have been recently much improved, are still characterhave been recently much improved, are still character-ized by great obscurity and complexity, so as to be frequently unintelligible, and even contradictory. It is one of the principles regarding taxation laid down by Adam Smith, that "the time of payment, the man-ner of payment, the quantity to be paid, ought all to be clear and plain to the contributor, and to every other person." But so far from this being the case, there were, in 1836, no fewer than 620 acts of parliament relating to the excise; and at no distant period there were some forty or fifty acts in existence referring to the glass forty or fifty acts in existence referring to the glass duties alone. We believe that were the duties reduced to a reasonable amount, and assessed so as to interfere as little as possible with the operations of the manu-facturer, the laws made concise and intelligible, and the legal proceedings placed on a proper footing, whatthe legal proceedings piaced on a proper footing, whatever prejudices may exist against the excise would speedily disappear; for it enjoys certain advantages over every other mode of taxation. (See Taxation.) The net amount of revenue yielded by the excise duties in 1850 was £14,316,081; in 1855, £16,389,486; and in 1860, £18,189,605. The following table exhibits the 1869, £18,188,695. The following table exhibits the net receipt of the daties of excise in the United Kingdom in the years ended 31st March, 1868 and 1869 (the latest returns). The duties on railways, stage carriages, and racehorses are levied in Great Britain only; and on hackney carriages in London only. The duty on chicory is levied only in England.

EXCLAMATION, eks-klii-mai shun (Lat. exclame, I ery out), a term in Gram. susceptible of different signifi-cations, but which is usually accepted as an interjection, signifying sudden emotion, expressive of wonder, alarm, or joy. It is usually uttered by a vehement and sudden extension or elevation of the

EXCOMMENICATION, cks-kom-mu-ne-kai'-shun (Lat.), is an ecclesiastical consure or penalty, by which per-sons who have been guilty of any notorious crime or offence are cut off from the communion of the Church, and deprived of all ecclesiastical privileges. Excommunication is founded upon the natural right of all societies to exclude from their body such as contravene the established laws. The Jews expelled from their synagogue such has had committed any grievous crime; and the same was the practice in the religious system of heathendom. Among the early Christians excommunication was instituted for the purpose of preserving the purity of the Church and enforcing its discipline, though it came afterwards, in the hands of ambitious ecclesiastics, to be used as a means of advancing their own power, and was inflicted on the most frivolous occasions. The power of excommunication was lodged in the hands of the clergy, who distinguished it into the greater and the less. The latter consisted in excluding persons from participation in the Eucharist and the prayers of the faithful; the for-mer deprived them of all the rights of the Church, and even cut them off from the society and conversation of the faithful, no one being allowed to receive an excommunicated person into his house, or to sit at the same table with him. He who was guilty of any intercourse with an excommunicated person, himself incurred the same sentence. Excommunication was early introsame sentence. Excommunication was early intro-duced into England as a means of ecclesiastical pun-ishment; but many then were obstinate and profans-enough to despise the britism fulmen of mere church censures; and so the common law stepped in to sid the Church, and declared that an excommunicated

#### Execution

person is disabled from doing any act that is required to be done by a probus et legalis homo. He thus could not serve upon juries, could not be a witness in any court, and could not bring an action, real or personal, to recover lands or money due to him. And further, if within forty days after the sentence the offender did not submit and abide by the decision of the spiritual court the histon wight cartify such actions. court, the bishop might certify such contempt to the king in chancery; upon which there issued out a writ to the sheriff of the county, called, from the bishop's certificate, a significant, or, from its effects, a writ de excommunicate expiendo; and the sheriff might thereupon take the offender and imprison him in the county gaol till he was reconciled to the Church, and such gaot in ne was reconcined to the Church, and shen reconciliation certified by the bishop; upon which another writ, de excommunicato deliberando issued out of chancery to deliver and release him. But by 53 Geo. III. c. 121, it is declared that no person who shall be pronounced or declared excommunicate shall incur any civil penalty or incapacity in consequence of such excommunication, save such imprisonment, not exceeding six Lionths, as the court pronouncing or declaring such person excommunicate shall direct." By that statute, excommunication can only be pronounced as spiritual censure for offences of ecclesiastical cognizance,—adultery, heresy, simony, and the like; but the practice has long become obsolete.

EXECUTION, cks-c-ku'-shun (Lat. ex, out; secutus, followed), in a general sense, is the performance of any act or duty. In Law, it is the last stage of a suit giving possession of anything recovered at law or in equity after the decision of the court,—the putting in force of the sentence of the court. This is performed by different writs of execution, according to the nature of the action, and of judgment. In ordinary actions, the judgment is, in general, for the recovery of money only, either by way of debt or damages. In such case, the practice of the court allows the judgment-creditor to resort to one of the four following writs of execution:—(1) Writ of capias ad satisfaciendum, to imprison the body of the debtor till satisfaction be made for the debt, or damages and costs; (2) writ of fieri for the debt, or damages and costs; (2) writ of fieri fucias, by which the goods and chattels of the party against whom the jndgment is recovered may be seized upon and sold; (3) writ of levari fucias, which commands the sheriff to levy the debt on the lands and goods of the party against whom it is issued; (4) writ of elegif. (See FLEGIT.) Where the judgment is for the recovery of goods themselves which are detained, there is a special writ of execution, called a distringas, to compel the defendant to deliver the goods by repeated distresses of his chattels, or else scire facius against any third person in whose hands a scire facias against any third person in whose hands they may happen to be, to show cause why they should not be delivered; and if the defendant still continues obstinate, then the sheriff shall summon an inquest, to ascertain the value of the goods and the plaintiff's damages, which shall be levied on the person or goods of the defendant. The 7 & 8 Vict. c. 98, abolished arrest for debts under £20, unless contracted by

EXECUTION OF DREDS is the signing, scaling, and delivery of them by the parties, as their own acts and deeds, in the presence of witnesses. Execution is also the last stage in criminal proceedings,—the de-priving the criminal of his life. (See Capital Punish-Ment.)

EXECUTIVE, eks-ek'-u-tiv, in Pol., is a term applied to a power in 3 state, distinct from the legislative or judicial. The power that deliberates and enacts laws is the legislative, that which judges or applies the laws to particular cases is the judicial, while the executive is that which carries the laws into effect, or superintends the enforcement of them. In England, the executive is that which contribution are superintends the enforcement of them. the executive is, by the constitution, supposed to be vested in the king and such inferior officers as he may appoint.

appoint.

Executors, eks-ek'-u-tor (Fr. exécuteur), is a person intrusted by a testator to carry out the directions and requests in his will, and to dispose of his property, as directed therein, after his decease. When ne executor is named by will, or when those named refuse to act, then the Probate Court nominates certain persons to act as administrators to the deceased. Before probate of the will, an executor may effectually do most

#### Exegesis

of the acts that he could enforce afterwards; but an expected administrator can properly do no act what-ever before obtaining letters of administration. An administrator, after receiving letters of administration, is in most respects in the same position as an executor, and the cases relating to the one apply, in general, to those of the other. In Scots law, administrators are termed executors datios, i.e. appointed by the court; the other class being executors nominate, i.e. appointed by will. The right to nomination as administrators are outerned dation; i.e. appointed by will. appointed by will. In eright to nomination as adminis-trators or executors dutive is, generally speaking, in the order of relationship to the deceased. In England, the widow or next of kin have the first right to be appointed, and, failing them, creditors; in Scotland, persons entitled to the estate by a general settlement have a right to be appointed before others, and then the next of kin. An administrator is required to enter into bond with sureties for the faithful execution of his trust. An executor may refuse to act; but, having once acted, he cannot divest himself of the office or its responsibilities. If a person take upon himself to act as executor without any just authority, as by intermeddling with the goods of the deceased, he is called an executor de son tort, i. e. to his own hurt, and is liable to all the trouble of his office, without any of the profits or advantages; but merely doing acts of necessity or humanity, as locking up the goods, or burying the deceased, will not be so construed. An executor is not entitled to any remuneration for his own personal trouble or loss of time, unless it be expressed in the will. The duties of an executor are expressed in the will. The duties of an executor are to bury the deceased in a suitable manner, to prove the will, and make up an inventory of the personal estate; to collect the goods and chattels of the deceased, and to pay his creditors in the order of legal priority. The legacies are then to be paid as far as the assets extend, observing the distinction between a specific and a general legacy, the residue, if any, going to the next of kin. The office of an executor is one of great trust and responsibility, as he not only repregreat trust and responsibility, as he not only repre-sents the deceased, but is also a trustee for behoof of the creditors, legatees, and next of kin, of the de-cased. He is liable for any loss occurring to the estate ccased. He is hable for any loss occurring to the estate through negligence; for paying sums not due, unless upon decrees; for paying simple-contract creditors before special creditors, or legatees before all the debts are discharged, if there should be any deficiency in the estate. If he intromit with the funds or moverables, so as to lead to a suspicion of fraud, or so as to leave no manner of acceptaining its extent he is liable. leave no means of ascertaining its extent, he is liable for all the debts of the deceased; otherwise, an execu-tor is liable for the debts of the deceased only to the

tor is liable for the debts of the deceased only to the amount of the inventory.

EXEDEA, ets-ed'-rā (Gr. exedra), the name given in ancient architecture to recesses generally furnished with seats, which were placed in the halls and portices of public and private buildings, and in the Roman. baths and Greek palaestræ. They appear to have been similar to the modern alcove, though on a larger scale.

Execuse etra-eig-sig (Gr. Fromer, ext. of execuse).

EXEGESIS, ets-e-je'-sis (Gr., from ex, cut of; egeomat, I lead), properly signifies the exposition or interpretation of any writing, but is almost exclusively confined to the interpretation of the sacred Scriptures. Exegesis is frequently confounded with hermeneutics. This distinction between them is thus given by Dr. Davidson :-- "The meaning of all language, written or spoken, is developed by the application of general laws, usually termed kermeneutics. These principles, in their usually termed kermeneutics. These principles, in their relation to Scripture, are styled sucred kermeneutics; and their application to particular instances has received the name of exegesis." Hermeneutics, then, is the science which lays down the principles of the art of interpretation, and exeges is the application of these principles to particular instances. As the sacred books were written in foreign languages, by authors of a different age, and living in a country different from ours, it is evident, that in order to understand from ours, it is evenent, that in order to understand them thoroughly, requires not only an intimate ac-quaintance of these languages, but also a large mass of historical, recognaphical, and antiquarian knowledge. In the early ages of the Church, several of the fathers distinguished themselves as exegetical authors, as Origen, Chrysostom, Diodorus of Tarsus, and Jerome; but during the middle ages, from the ignorance of the sacred languages that then prevailed, the subject was

#### Exercise

almost entirely neglected. The Reformation revived this study in the labours of Luther, Mclancthon, Calvin, Zwinglius, Bezz, and others. Since that time,

this subject has been receiving more and more attention at the hands of scholars, and never more than in the present day, more especially in Germany.

EXECUSE. (See GYMMASTICS.)

EXETTE COLLEGE, Oxford, eks'-ster, was originally founded in 1314, by Walter de Stapledon, bishop of Exeter, and some time lord high treasurer of England, and was then called Stapledon Hall. The bishop re-moved hither his scholars from Hart Hall, and made a foundation for a rector and twelve fellows. Thirteen fellowships were subsequently added by different donors; but in 1855, under powers granted by 17 & 18 Vict. c. 81, these fellowships were reduced from twentyvice. c. 81, these renowants were reduced rich wenty-five te fifteen, and the restrictions with which they were burdened removed, so that they are now open without any preference with respect to birth. Candi-dates must be members of the Church of England, or of some church in communion with it, and must have essed all the examinations required by the university passed all the examinations required by the division of for the degree of B.A., or have been admitted ad eundem gradum of the university, or have become in any way a member of convocation. From the revenues of eight suppressed fellowships, twenty-two scholar-ships are founded; ten of which are open, ten (called ships are founded; ten of which are open, ten (catted Stapledon scholarships) are limited to persons born or educated in the diocese of Exeter, and two to persons born in any of the Channel islands, or educated at Victoria College, Jersey, or Elizabeth College, Guern-sey. The revenues of the two remaining fellowships were divided among the rectorship and the fifteen fellowships. There are also twenty exhibitions at-taohed to this college, but eleven of them are not in its immediate off. The number of members on the backs immediate gift. The number of members on the books in 1862 was 607.

in 1862 was 607.

EXHALATION. (See EVAPORATION, VAPOUE.)

RHEIETTONS, ART, eks-s-bish'-uns (Lat. exhibitio), displays open to the public, free or otherwise, of the works of living or deceased artists, mostly with the view of gaining purchasers for the paintings and instructing the national character. For more than a century and a half these great incentives to art have been carried out, and art exhibitions have become indeed popular institutions amongst nearly all the nations of Europe. In most European towns these exhibitions take place annually, and in France and England they are, in fact, of more frequent recurrence. In the middle ages, and up to the middle of the 17th century, when art was patronized only by the government, the priesthood, or the nobility of the different nations where art sprung up, the works of artists were deposited in public buildings or churches open to the public, so as to spread the artist's fame, and thus add to his prosperity and reputation; but when private patronage became the artist's mainstay, and when his works, if purchased, would be sure to be buried, as it were, in private houses, where none but a small circle century and a half these great incentives to art have his works, in profused, would be sure to be buried, as it were, in private bouses, where none but a small circle could see them, it became necessary for the artist to have some public exhibition, whereby the public generally might see his works and judge of his talents before they were hidden away in the dwellings of their purchasers. Probably the earliest art exhibition was that which was started by the members of the Academy of Fine Arts at Reme: anything before this could not have been of any open or general character, being conhave been of any open or general character, being con-fined to the works of some particular master and his pupils. That of the French Academy, in the year 1673, was the first art exhibition, in the true sense of the word in which we take it; but this was not place on a very firm basis. In the year 1745 it was once more regularly instituted, and an exhibition of fine arts took place bisensially from that date down to the days of the Revolution. While the days of the barri-cades lasted, it was thrown open to all foreign artists, and in the year 1795 it was restored to the form of a cades lasted, it was thrown open to all foreign artists, and in the year 1796 it was restored to the form of an annual exhibition. In England, however, art was more tardy, for it was not until the year 1769 that the regular exhibitions of the Royal Academy commenced. From that date down to the present time art exhibitions have steadily increased, and in London, in From that dats nown to the present time art ex- 1239 to 2514 inclusive, from the death of Joseph to the hibitious have steadily increased, and in London, insected of one, we can number some ten or twelve art stead of one, we can number some ten or twelve art ording to Rivet, are quoted from Exodusby our Saviour exhibitions which are opened every year. To show the increased sest which these exhibitions have given to sions to the same are made in the New Testament."—

## Exedus

the prosecution of art, it may be stated, that in the the prosecution of art, it may be stated, that in the first exhibition of the Academy in the last century, the number of works exhibited was only 130, and the number of exhibitors 69; while in 1862 the number of exhibitors 69; while in 1862 the number of the thiotical was upwards of 1,000. One of the most memorable of fine-art exhibitions was that of Manchester in the year 1857, which met with a success somewhat similar to that of the Industrial Exhibition of 1851. The value of the works exhibited is stated to have been more than \$6 000 000 and these is stated to have been more than £6,000,000; and these were lent gratuitously by their possessors, in order that the public might obtain a sight of masterpieces which existed, it is true, but whose existence was unknown and unthought of by the world at large. In the Exhibition of 1862, great space was left for the exhibition of fine arts. (For further information see article OR INTERNATIONAL AND INDUSTRIAL EXHIBITIONS.)

EXHIBITIONS, INTERNATIONAL AND INDUSTRIAL. (See International and Industrial Exhibitions.) Exibia, ek.sid'-e-a, in Bot., a gen. of Fungi. The species E. Auricuk Judæ, Jew's ear, is reputed to possess astringent and discutient properties, when appossess astringent and ascurent properties, when applied externally as a decoction or poultice. E. hispadula is used in China as a styptic, and as food mixed in soups and hashes. It is known there under the name of Moghi, which signifies ears of trees.

EXILE. (See BANISHMENT, TRANSPORTATION.)

EXISTENCE, eg.-zis-tens, means the state of being, duration, or continuation. In mental philosophy, it

According to all theories, existence must have been, even of chaos, before the Adamite world, and it will

continue to eternity.

Exit, eg'-zit (from the Latin exire, to go out), signihe str. eg. - i (from the latin extre, to go out), signifies the departure of an actor or player from the stage, when he has performed his part in any particular scene or act. It is also applied to the termination of one's career or state of existence. It is usually placed in the margin of plays, as a guide to the actor or

reader.

Exonus, eks'-o-dus (Gr. exodos, a going out, a de-parture), is the name given to the second book of the Old Testament, as containing a narrative of the de-parture of the children of Israel out of Egypt under parture of the children of Israel out of Egypt under the guidance of Moses. In Hebrew it is termed ve-uleh Shemoth,—'these are the names,'—from the words with which the book begins. Exodus may be divided into two principal parts: (1) Historical (i. 1—xviii. 27), comprising (a) the preparation for the deliverance of Israel from their bondage in Egypt, and (b) the acomplishment of that deliverance; and (2) Legislative (xix. 1—xl. 38). In the first section we have an account of the great increase of Jacob's posterity in the land of Egypt, and their convession under a new dyland of Egypt, and their oppression under a new dynasty, which occupied the throne after the death of Joseph; an account of the birth, education, and flight of Moses; his solemn call to be the deliverer of Israel. and his return to Egypt; his ineffectual attempts to prevail upon Pharaoh to let the people go, the indiction of the ten plagues, and the institution of the passover. Then follows a narrative of their departure out of Egypt, their passage through the Red Sea, with the destruction of Pharaoh and his host in the midst of it; the principal events on the journey from the Red Sea to Mount Sinai; the bitter waters at Marah, the qualis, the manne, the water from the rock at Rephidim, the hattle with the Amalabitas and the await of Tathen battle with the Amalekites, and the arrival of Jethro with Moses's wife and children in the Israelitish camp In the second part of the book we have the promulan one second part of the book we have the promut-gation of the law on Mount Sinai, the preparation of the people by Moses for the renewing of the covenant with God, the promulgation of the moral law, the judicial law, and, lastly, the ceremonial law, including the construction and erection of the tabernacle. In chap, xxxii.—xxxiv. we have an account of the idolatry of the Israelites, the breaking of the two tables of the law, the divine chastisement of the people, and the re-newal of the tables of the covenant. This book "comnewsl of the tables of the covenant. This book "com-prises a history of the events that took place during the period of 145 years, from the year of the world 2309 to 2514 inclusive, from the death of Joseph to the

810

## Ex officio

(Horne.) Mr. Horne also adopts the generally received opinion that Moses was the author of this book; but there have been many learned critics, both Jews and Christians, of a contrary opinion. There are many difficulties connected with this book, which have been attempted to be explained in different ways; some bolding that it is the work of a much later author than Moses; others that it is the work of two distinct authors, hiving at different times; a third party that it abounds with interpolations, and so on. This subject has received a fresh interest from the publication, by Dr. Colenso, bishop of Natal, of a work on the Pentatench, in which be gives forth views which are not regarded as orthodox. "I have arrived at the conviction," he says, "as painful to myself at first as it may be to my reader, though painful now no longer under the clear shining of the light of truth, that the Pentateuch, as a whole, cannot possibly have been written by Moses, or whole, cannot possibly have been written by Moses, or by any one acquainted personslly with the facts which it professes to describe; and further, that the (so called) Mosaic narrative, by whomsoever written, and though imparting to us, as I fully believe it does, revelations of the divine will and character, cannot be regarded as historically true." It remains to be seen what arguments are to be brought forward against the history actatometric most of which howevers have the hishop's statements, most of which, however, are not new, and some of them are sufficiently weak. We cannot, however, enter upon the subject, but would refer those who wish to get the arguments in favour of the commonly-received opinions on this subject, to the works of Hengstenberg and Hävernick on the Penta-

EX OFFICIO, eks-of-fish'-e-o (Lat., by reason of office or duty), a term applied to an act done in execution of a power which a person has by virtue of his office. In a power which a person has by virtue of his office. In legal phraseology, ex-officio informations are informations at the suit of the Queen, filed by the attorney-general, by virtue of his office, without applying to the court wherein filed, for leave, or giving the defendant an opportunity of showing cause why it should not be Ex-officio criminal informations are used in official prosecutions in cases of libel, sedition, &c.

EXOGENS, eks'-o-jens (Gr. exo, without; ginomai, I am formed), in Bot., plants with stems that increase by external concentric layers,—as the beech, ash, and oak. The class Exogenæ of some botanists corresponds with the class Dicatyledones (which see).

Exogonium, ex-o-go'-ne-um (Gr. exo, without; gonia, angle), in Bot., a gen. of Convolvulacex. The species E. purga is a native of Mexico, near Chincanquiaco. Its tubercular roots constitute the true jalap of the Materia

Medics, so well known as a purgative.

Exoncism, eks'-or-sizm (Gr. exorkizo, I conjure), is the conjuration of evil spirits, in the name of God or Christ, to depart out of a person possessed. In the early ages of the Church, when persons were about to be haptized, they were called upon to make a solemn renunciation of the devil and all superstitious practices and worship; but afterwards, about the 4th century, when all idolaters came to be looked upon as possessed of devils, it became customary to exorcise them previous to their being baptized. Soon afterthem previous to their being captized. Soon atterwards it came to be a form generally employed in haptism even of children of Christian parents, who were also regarded as possessed by the devil before baptism. The words employed were, "I adjure thee, unclean spirit, that thou come out of this servant of Jesus Christ; in the name of the Father, and the Son, and the Holy Ghost." Exorcism was retained by and the Holy Chost." Exoreism was retained by Luther, but was laid aside by the Reformed church. The Roman Catholics employ exorcism in three dif-ferent cases;—in the administration of baptism, in actual or supposed demoniacal possession, and in the blessing of the chrism and holy water. EXCEDIUM, else-or'-de-um (Lat. exordior), is the intro-

# Expectorants

and directly professes his aim in speaking. In the latter the orator must take a larger compass, and, presuming the disposition of the audience to be against him, he must gradually reconcile them to hearing him before he plainly discovers the point which he has in view.

Excamose, eles-of mose (Gr. ex, out of; osmos, impulsion), the passage from within outwards of fluids or gases through a membranous separation. (See ENDOSMOSE.)

Exostosis, eks-os-to'-sis (Gr., from ex, out of, and osteon, a bone), in Surg., is a term applied to a murbid enlargement or hard tumour of a bone. This term is applied properly only to osseous tumours on the bones, though it is also sometimes applied to other morbid growths. Exostoses are easily d stinguished from other swellings by their being fixed and immovable, and at first unattended with any pain or inconvenience. There are three varieties,—the solid, the hollow, and the foliated. There is no bone that may not become the seat of this disease, though some are much more subject to it than others. No external transment is of our benefit in this disease and when treatment is of any benefit in this disease; and when it is necessary that they be removed, and can be done with safety, it is effected by sawing or cutting.

with safety, it is effected by sawing or cutting.

Exotro, ets-or-ik (Gr. exotikos, foreign), a term applied to the produce of foreign countries. In gardening, exotic plants are those which belong to a soil and climate entirely different to the place where they are raised, and are therefore mostly preserved in green-houses. Exotic plants from hot climates are

green-nouses. Exous plants from not climates are very numerous, and require much attention: without great care, even if they do blossom, it is seldom that they produce fruit, or that their seeds ripen. EXPANSION, eks-pān'-shun (Lat. expansio), a term applied to the enlargement or increase of bulk in bodies, generally produced by heat. This effect is one of the most common and obvious results of the raising of temperature in all bodies, solid and liquid. Among the solids, the metals are the most expansible by heat. Experience has taught our engineers that it is dangerous to confine such a force as this, and that it is necessary to make provision for it in metallic constructions. The arches of Southwark bridge rise and fall about an inch in the usual range of atmospheric temperature, and if provision had not been made for the expansion and contraction of the iron, destructive consequences must have ensued. In most cases, all bodies contract when the temperature is lowered; but there is a remarkable exception to this rule in the case of water, which begins to expand when lowered to 46° Fabr. (See WATER.) The power evolved in the expansion of water is very great. A brass globe having a cavity an inch in diameter can be burst by filling it with water and freezing it, when the absolute force necessary to produce a like result is equal to 27,720 ibs. weight. Aeriform bodies are the most expansible forms of matter, and they all expand and contract

EX PARTE, eks-par'-te (Lat., of one part), in Law, is a phrase used in chancery proceedings, when a commission is taken out and executed by one side or commission is taken out and executed by one side or party, the other party refusing or neglecting to join therein. When both parties join, it is called a joint commission. Hence the term exparts has come to be applied, in common language, to any statement or evidence coming from one of the interested parties. EXPECTORANTS, eks-pek-te-rants (Lat. ex, out of, and pectus, the cheet), is a term applied in Med. to such substances as promote the expulsion of mucus, or other matters, from the air-massaces of the throat and

such substances as promote the expusion of mucus, or other matters, from the air-passages of the throat and chest. The agents that are used with this view are very different, and act in different ways. Vapours are the only agents that can act directly upon the organs affected; those that are taken into the stomach being EXORDIUM, ess-or-de-um (Lat. exerdior), is the intro-duction or opening part of an oration, and, according to Cicero and Quintilian, it ought to have one or other of three ends in view:—(1) to render the hearers bene-volent, or to conciliate their good-will; (2) to excite their attention; or (3) to render them docile, or open to persuasion. An exordium should be easy and na-tural, and drawn either from the subject itself or from the situation of the speaker. The ancients distin-guished two kinds of introductions,—the principium and insimuatio. The former is where the orator plainly pipe, and produce coughing, act as expectorants.

When there is decided inflammation, the best expectorants are such as lessen the inflammatory state; and hence mustard, or a fly-blister, applied to the chest, or venesection, will be found to be of the utmost service. Great care is necessary to be observed in the selection of the particular agent to be employed in each case, and very great injury may be done by having recourse to such as are unsuitable.

EXPERIENCE, eks-pe'-re-ens (Lat. experientia), can strictly speaking, he applied only to what has occurred within a person's own knowledge, and in this sense, of course, can only relate to the past. Thus, a man knows by experience what sufferings he has undergone in a certain disease. Frequently, however, the word is used to denote a judgment derived from experience in its primary sense; and thus only can experience be applied to the future, or any general fact; as when it is said that we know by experience that water at a sertain temperature will freeze.

EXPERIMENT, eks-per-c-ment (Lat. experimentum, an attempt), an operation for the purpose of discovering some unknown truth, principle, or effect, or to establish it when discovered. Experiments are of great importance in physical science, and in chemistry they disclose the qualities of natural bodies.

Experimental Philosophix is that which deduces the laws of nature, the properties of bodies, and their mutual actions upon one another, from experi-ments and observations. The distinction between deductive and experimental philosophy is clearly pointed out in the following quotation from Sir John Herschel:—"A clever man shut up alone and allowed Merschel:—A cieve man show up more an amount mulminited time, might reason out for himself all the truths of mathematics, by proceeding from those simple notions of space and number of which he cannot divest himself without ceasing to think; but he could never tell by any effort of reasoning what would become of a lump of sugar if immersed in water, or what impression would be produced on the Experieye by mixing the colours yellow and blue. mental philosophy is consequently founded on ocular demonstration, or that which cannot be denied without violating common sense or clear perception. INDUCTIVE PRILOSOPHY.)

EXPERIMENTUM CRUCIS, eks-per-e-men'-tum kru'-six (Lat., experiment of the cross), a leading or decisive experiment, either so called on account of its being like a cross or direction-post, placed by the roadside in order to guide travellers in the right path, or on account of its being a kind of torture to elicit the truth, as the cross was used like the rack for that pur-

pose in ancient times.

EXPLOSION, eke-plo'-zhun (Lat. explosio), sudden expansion or bursting of any substance, accompanied by a loud report; as the explosion of gunpowder, an explosion of a steam-boiler, an explosion of gas.

plosion or gas.

Exposization, ex-por-tai-shun (Lat. ex, out, and porto, I carry), the act of sending commodities out of one country into another. (See Communic.)

Ex-root-racro, ets-poat-fak-to (Lat.), a law phrase which is applied to something which has already been

done or proved. For instance, a law is said to be made ex-post-facto when it renders an offence in a manner in which it was not punishable at the time it was committed; that is, a law made for the offence

EXPRESSION, eks-presh-nn.—In the Fine Arts, this term is applied to the representation of the various passions of the mind, as shown in facial devevarious passions of the mind, as shown in facial development. Sir Joshus Reynolds, who may be said to be the father of the English school of painting, directs that all attention must be paid to expression. He says,—"Care must be taken not to run into peculiarities. Those expressions alone should be given to the figures which their respective situations generally produce. Nor is this enough; each person should also have that expression which men of his rank generally whith The document of the proof of a character of rally exhibit. The joy or the grief of a character of digatry is not to be expressed in the same manuer as a similar passion in a vulgar face."

Expugationers Index. (See Index Expurations)

defined to be the power of clearly and forcibly expressing oneself upon any subject without previous preing oneset upon any surject without previous pre-paration, at least as regards the words; for, strictly speaking, every extemporized speech presupposes a preliminary operation of thought. Before extempo-rizing a speech, it is necessary to have the foundation of the discourse fixed in the mind, and the succession of thoughts to be expressed. There should reign between all its parts an order of fliation, or generation, the one idea naturally producing the other; and they should be so disposed, that each may be found in the very place marked out for it, the moment it is required. The great requisite in extempore speaking is to have clear and distinct ideas regarding the subject on which one is shout to speak. In order to speak forcibly and clearly, one must begin by feeling vividly, and then clear ideas on the subject will naturally follow. It should not, however, obtain such possessi in of the mind as to prevent it from acting; for the mind of the mind as to prevent it from acting; for the mind of the apeaker may become so completely absorbed by the contemplation of his subject, as to be unable to enter upon its development. This forms a stumbling-block to many in attempting to become good speakers; and it frequently occurs with men of genius. He, therefore, who would speak well must feel what he has to say, with sufficient strength to express it with warmth and vivacity; but his feeling must not attain that vehemence which prevents the mind from acting, and accuracy the expression from its very fulness. In paralyzes the expression, from its very fulness. speaking, the feelings have to be resolved into ideas, thoughts, images; and these into words, phrases, lan-guage. The main idea of the subject has to be firmly grasped; and in its exposition it has to be divided into its principal parts or members, and these into subordinate parts; and so on, until the subject is exhausted. The imagination is one of the most necessary faculties to the extempore speaker: it ought to be endowed with great quickness in the formation and variation of its pictures, and also with great clearness, in order to produce, at first effort, a well-marked image, the lines and outlines defined with great exactness, and the colours bright, so that language has only to reproduce it unhesitatingly and unconfusedly. In many men, even of talent, the imagination is not sufficiently ready In many men, and clear; it works too slowly, owing either to a natural deficiency, or, more frequently, a want of prac-tice. To many, again, the excitement of appearing in public is so great as to produce a certain incapacity of speaking, not unlike inability to walk from giddiness. The great means of getting over this is to feel per-The great means of getting over this is to feel perfectly sure of what you are going to say, and to have a clear conception of it. The public speaker requires to be able to think methodically; and for that purpose he ought to study logic, and the works of the best authors; he ought, also, to acquire such a mastery over his cwn thought, as to be able to decompose it into its parts, to analyze it into its elements, and then, at need, to re-compose, re-gather, and concentrate it again by a synthetical process. Now, this can only be again by a synthetical process. Now, this can only be well done by writing; and hence, one ought to begin by learning to write, one must write in imitation of the great masters of oratory. Writing gives wonderful clearness and intensity to thought, and enables us to look at a subject in every light. In the consideration of a subject, the best way is first to seize hold of the main idea, and regard it intently for some time, the different faculties of the mind concentrating thems upon this single point; the subject is thus turned over in every direction, and viewed in all its aspects; its principal parts then gradually come out and separate themselves from each other, becoming more and more developed, until they reach their perfect form. The public speaker should have his mind well stored with information on a great variety of subjects, more particularly such as are regarded as forming part of a liberal education; for we can only extemporize what is already in the mind. It is of importance, too, that all we know be strongly conceived, firmly linked togea similar passion in a vulgar face."

Expusedatorius Index. (See Index Expusedatorius,)

Expusedatorius Index. (See Index Expusedatorius,)

Expusedatorius Sprakies, eks-tem'-pore (Lat. ex, and to a certain extent, by maditation. Further, in public temporarius, lasting but for a time, temporary) may be speaking, thought has to be clothed in language; and ther, and carefully wrought out in such a way that,

some attention to this is likewise necessary, in order that the sui-ject may appear in as favourable a dress as possible. For this purpose, one ought to cultivate assiduously that natural desire of communicating to others what he knows, and of making them see things in the same light that he sees them. The mind seizes upon a thing more quickly, and conceives it more clearly, when there is also present to the mind the ides of communicating it to another; and thus, also, a natural desire is fostered for public speaking. In the details of diction, at the moment of public speaking, great decision is necessary, in order to clothe the ideas in proper words as they fly past, and, amidst many unsuitable, to allow none but such as are proper to escape from the lips. The speaker, however, at first ought not to be too nice in this respect; especially, when once he has begun a sentence or an idea, he ought to go on daringly to the end, even though he may have to take refuge in some incorrectness of language, or some unauthorized turn of expression. Decision, and even rashness, are necessary for him who would make a good public speaker. Finally, "the understanding which sees rightly and conceives clearly, and the heart which feels keenly, soon come to find naturally, and without effort, the words and the arrangements most analogous to what is to be expressed."—Ref. The Art of Extempore Speaking, by M. Bantain, 1858.

EXTRNSION, ekc-ten'-shun (Lat. extensio, a stretching) in Logic, is a term used in contrast to comprehen sion, and, as applied to a general notion, it denotes the number of objects included under it. By detach-ing properties from a notion, we extend the list of objects to which it applies; by narrowing the sphere of a notion, the qualities which it comprehends proportionally increase. Thus, the greater the extension of common term, the less the comprehension, and

EXTENT, OF EXTENDI FACIAS, eks-tent', in Law, is a writ of execution issuing out of the court of Exchequer, and directed to the sheriff, against the body, lands, and goods, or the lands only, of a debtor. The sheriff is to cause the lands, &c. to be appraised to their full extended value before he delivers them to the their full extended value before he delivers them to the plaintiff, in order that it may be certainly known how soon the debt will be satisfied. The king, by ancient prerogative, is mittled to this writ in order to recover debts originally due to him, or assigned to the crown. Extents are either in chief, or in aid. In extents in chief, the crown is the real plaintiff against a crown debtor; and under it his body, lands, and goods, may be taken at once. Extents in aid are sued out at the instance and for the benefit of the crown, against the adverse of a covery deliver. the debtor of a crown debtor.

EXTORTION, eks-lor-shun (Fr. extorquer, to draw from by force, from Lat. extorqueo, I wrest from), in Law, is an abuse of public justice, which consists in any officer unlawfully taking, by colour of his office, from any man, any money or thing of value that is not due to him, or more than is due, or before it is due. This is an offence at common law, punishable by fine and imprisonment.

EXTRA, eks'-tră, a Latin preposition, signifying over

and above, in excess; as, extra work, extra pay, &c.

Extra crs, ekr-trakts (Lat. extractus), medicinal
preparations obtained in a variety of ways from vegetable sources. Sometimes they consist of the simple evaporated juices of the fresh plant, and at others they consist of certain principles extracted from the fresh or dried plant by means of a menstruum capable of dissolving them. They are termed watery, alcoholic, acetons, or othereal, according to the menstruum employed. The object is to preserve the principles from putrefaction, which was likely to occur while they remained associated with or dissolved in other portions of the plant. They are also thus more readily used in making pills, &c. The preparation of extracts requires great care. A great improvement was introduced by Mr. Barry in the mode of preparing extracts by evaporating in vacuo. Compound extracts are those

delivery by one nation or state to another of fugitives from justice, in accordance with treaty.

EXTRAVARION, Eds.-frdv-d-ad-j-skun (Lat., from extra, without, and vas, a vessel), in Surg., is a term applied to fluids which are out of their proper vessels or receptacles.
Thus, an extravasation of blood takes place when an artery or vein is injured, and the blood escapes into the cellular membrane; and an extravasation of urine, when, in consequence of a wound or ulceration, that fluid makes its way into the cellular substance, or among the abdominal viscera. Extravasation is distinguished from exudation, in that, in the latter case, the walls of the vessels remain entire, and the fluids escape by secretion. It is nearly synonymous with effusion, but is not so comprehensive. The discoloration that follows contusions is occasioned by the extravasation of blood into the cellular tissue under the skin, from the rupture of small blood-vessels. When the ruptured vessel is large, or situated in a deli-cate part of the body, as in the brain, extravasation is usually fatal.

EXTERME UNCTION, eks-treme' unk'-shun (Lat. ex-tremus, last; unguo, I anoint), is one of the seven sacraments of the Roman Catholic church, founded upon that passage in the Epistle of St. James which says:—"Is any sick among you? let him call for the elders of the church, and let them pray over him, anointing him with oil, in the name of the Lord; and shall raise him up," &c. (v. 14, 15). This passage, it is said by Protestants, has reference only to the miraculous powers which were exercised in the time of the apostles. The rite of unction is frequently alluded to aposties. The rice of unction is inequency sauces by the fathers; but it, at that time, was common to several of the sacraments, and it was also employed as a means of restoring to health, as it is in the Greek church at the present day. It is called "extreme," because it is only for persons at the point of death,—
the closing ceremony of life. It is believed to purify the
soul of the dying person from any sins that he may
have committed, and to give him strength and grace
to encounter the last struggle. It is administered by
the priest, who, dipping his thumb in the holy oil, the priest, who, dipping his thumb in the holy oil, anoints the sick person in the form of the cross, upon the eyes, ears, nose, mouth, hands, and feet, each time saying, —"Through this holy unction, and his most tender mercy, may the Lord pardon thee whatever sins thou hast committed, by thy sight (hearing, &c.) Amen." The holy oil is blessed by the bishop every year with much solemnity, on Maundy Thursday. council of Trent passed several canons on this subject, declaring it to be truly and properly a sacrament in-stituted by Jesus Christ.

EXUVIE, egs-u'-vs-e (Lat.), a word applied to the cast-off skin of any animal, reptile, or shell-fish, which is "shed." The films of sucus thrown off by most molluses and zoophytes must also be regarded as exueve. In insects, the whole integument is shed annually, several times in succession, the last cadyris taking place in the final transition state, from the pupa taking place in the final transition state, from the pupa to the imago. In shell-fish, or crustacea, the external shell is usually cast yearly. The common snake, when confined, draws its skin off annually by means of pres-sure of the folds, and the rattlesnake is said to invert and draw off its own skin. In the more warm-blooded classes, the moulted feathers of birds and the hairs of various species of mammalia may be looked upon as exunia, or exuvial deposite; as also the small scales of what is termed searf-akin, which are continually east off from our way hedise. off from our own bodies.

Exe, 4 (Ang.-Sax.), the organ of vision, is one of the most wonderful and delicate portions of the human the most wonderful and delicate portions of the humas body. It is placed within a bony cavity, termed the orbit, pyramidal in form, with the base anteriorly, and directed a little outwards, and the apex backwards and inwards. The orbit contains the globe of the eye, with numerous muscles, nerves, vessels, fat, &c. The external appendages of the eye are the eyebrows, eyelids, and lachrymal apparatus. The eyebrows, or supercible, are arches of his covering the suing-orbital ridge evaporating in vacuo. Compound extracts are those which are prepared from several plants, and simple extracts from one only.

EXTRADITION, eks-trā-disk'-un (Lat., from ex, and trado, I deliver), denotes the delivery from one nation to another, and is more particularly applied to the

curtains which cover the eye, the one being inferior, the other superior. Where they join outwardly is called the external, and inwardly towards the nose, the internal canthus. The margin of the eyelids, which is cartilaginous, is called tarsus. Along the margin of each eyelid is a row of stiff hairs, termed cilia, or eyelids. lashes, and which serve to keep external bodies out of the eyes, and moderate the influx of light. Within the lids, near their edges, are numerous glandular bodies, named after their discovever, the *Meibomian* glands, and secrete an oily or mucilaginous fluid, which lubricates the eyes and lids, and facilitates their movements. The lacrymal gland is situated in a small depression of the frontal bone near the external canthus, and from it seven or eight canals issue, called the lacrymal ducts, and open on the internal surface of the upper eyelid; it secretes the tears, which then pass along the surface of the eye to the puncta lacrymalia, which are surface of the eye to the puncta tarrymuta, when are two callons orifices or openings, one in each lid, at the internal angle of the tarsus. From the lacrymal points the tears are conveyed by the lacrymal canals into the lacrymal sac, which is a membranous recep-tacle situated in the internal canthus of the eye. The nasal duct is a membranous canal, extending from the inferior part of the lacrymal sac downwards, backwards, and outwards, into the cavity of the nose. lacrymal caruncle (caruncula lacrymalis) is a small fleshy body, of a red colour, composed chiefly of mu-cous follicles, and situated in the internal canthus of the eye. The globe or ball of the eye is composed of membranes or coats, humours, vessels, and nervee. The membrana conjunction, or conjunctive membrane, is a delicate mucous membrane, liming the internal parts of the cyclids, and covers the whole of the anterior part of the globe of the eye. The outermost coat of the eye is the sclerotic (Gr. skleros, hard), so called from its hardness. It is a strong, dense, white, fibrous structure, covering about four-fifths of the ball, and leaving a circular deficiency in front, which is occupied by the covering the strong of the ball, and the covering the strong of by the cornea. The latter, so named from its horny appearance, is the transparent covering in front of the eye, its edges being slightly overlapped by the sclerotic coat. Externally it is covered by the membrana concoat. Externally it is covered by the monitorials con-junctive, and internally it is in contact with the mem-brane of the aqueous humour. It is convex anteriorly and concave posteriorly, and is composed of several lamine, or layers. The choroid membrane is of a black colour, and covers the internal surface of the sclerotic coat, with which it is loosely connected by connective tissue. Near its anterior margin it is thrown into numerous folds or processes, alternately long and abort, and which lie upon the edge of the lens and anterior portion of the vitreous humour: they are called ciliary striae or processes, and conjointly the corpus ciliars. On the outer surface of the choroid are seen the ciliary nerves and long arteries; next com-the veius called, from the peculiar manner of their arrangement, vena vorticosa; next is the tunica Ruyschiana, composed chiefly of ramifications of minute arteries, forming a beautiful network; and next to this is series, forming a beautiful network, and field this is the tunica pigmenti, composed of pigment-cells, usually of a hexagonal form, and secreting on its inner surface the pigmentum nigrum. The retina, or inner coat of the eye, consists of three layers of membranes, the outermost of which, in apposition with the choroid, is an extremely delicate membrane, termed the funica Jacobi. The middle one, tunica nervosa, is in reality the expansion of the optic nerve, and terminates at the edge of the ciliary processes. The inner coat is the edge of the ciliary processes. The inner cost is the fusica vasculosa retina, which is vascular in texture, and contains several minute branches of the central artery of the retina. settery of the retina. On the inner surface of the retina, at the back of the eye, and in a line with the sexis of the globe, is a circular yellow spot, called the limbus lateus, in the centre of which is an apparent orifice, named, after its discoverer, the foramen of Sömmering. The bris (Lat., arainbow), so called from its variety of colour in different individuals, may be regarded as a process of the choroid, with which it is continuous, although the two membranes differ in structure. It is a thin, flat, circular, membranous cursin, handpe vertically in the aqueous humour in front On the inner surface of the stracture. It is a time, i.e., currents, membrands cur-tain, hanging vertically in the aqueous humour in front of the lens, and having a central orifice, termed the pupil, for the transmission of light. Its auterior surface is coloured variously in different individuals,

and its inner surface is lined with a substance resem-bling the pigmentum nigrum, called the uvea. It divides the space between the corner and the lens into two chambers, communicating freely with each other through the pupil. The anterior chamber is about a fifth larger than the posterior, and is lined with a membrane, which secretes the aqueous humour. The external edge of the iris, by uniting with the choroid and selectic costs, forms a greyish circle, termed the ciliary circle or ligament. The iris is muscular in structure, and has great power of contracting or expanding the pupil, so as to admit more or less light into the interior of the cychall. In the anterior and posterior chambers in the great humans of the is the aqueous humour of the eye, which serves to dis-tend the cornes to allow the free motion of the iris, and to direct the rays of light as they pass through it. The crystalline lens is a transparent body situated behind and opposite to the pupil, while its posterior surface is received into a corresponding depression on the fore-part of the vitreous humour. In form it is double convex, the posterior surface being more convex than the anterior; and it is invested by a transparent membrane called the capsule, which contains also a small quantity of fluid, called the liquor Mor-gayns. The lens consists of concentric lamine, formed upon a hard, firm nucleus, and becoming softer as they tend to the outer surface. The vitreous humour, or corpus vitreum, lies in the concavity of the retins, eccupying about four-fifths of the eye posteriorly, and being perfectly transparent. It is inclosed in the hyaloid membrane, which also seads numerous processes invarids, so as to divide it into a numerous processes inwards, so as to divide it into a number of cells, and to equalize the pressure exerted on the different parts. It is ponetrated by branches of the central artery of the retina. The eyeball is moved about in its orbit by six muscles, four of which are straight (recti) and two oblique,—the superior and inferior. The four recti muncles have their origin at the apex of the orbit, and are inserted into the sclerotic coat near the cornea, above, below, and on either side. When acting together, they tend to fix and retract the eye; when together, they tend to it and retract the eye; when separately, to raise, depress, or turn it to one side or the other. The superior oblique rises with the straight muscles, proceeds forwards to the upper edge of the orbit, where it passes through a small pulley of bone or cartilage, by which its direction is changed; and its course is then backwards, outwards, and downwards, to be inserted into the scienotic coat. It serves to draw the eye downwards and outwards. The inferior oblique arises from a unute depression in the orbital plate of the superior maxillary bone, just within the margin of the orbit, at its lower part, whence it passes backwards, outwards, and upwards, to be inserted into the sclerotic, at its posterior part. Its action is to direct the eye upwards and inwards. The optic nerves, or second pair, after uniting to form the optic com-missure, in which some of the fibres of each nerve cross to the opposite side, separate, and enter the optic foramen at the aper of the orbit. They pass through the sclerotic coat on the inner side of and below the axis of the eye, then through the choroid, and arread themselves out and are lost or terminate and spread themselves out, and are lost or terminate in the retina. Branches of the third, fourth, fifth, and sixth pairs of nerves also proceed to the eye, for regulating the movements, &c. of the different parts. In sight, then, the rays of light in passing through the cornea are converged, so as to pass through the rela-tively small pupil, and impinge upon the lens, which, by the convexity of its surface and its greater density towards the centre, serves to converge the rays, and to correct the aberration. They then traverse the vitreous humour, and strike upon the retina. OPTICS.)

OPTICS.)

EYE, DISEASES OF THE.—This organ, from its delicacy and the numerous parts of which it is composed, is subject to a great variety of diseases, most of which will be noticed under their own names in different parts of this work. (See AMAUROSIS, OPERMALMYA, &c.) We shall here, therefore, only give an account of cataract, which has been referred to this place. It is derived from the Greek verb katarasso, I disturb or confound, and is usually defined to be a weakness or interruption of sight, produced by opacity of the arystalline lens or its capsule. Sometimes it is applied to every perceptible obstacle to vision situated in the

#### Ezekiel

posterior chamber between the vitreous humour and the uses. When the disease is situated in the uses of its capsule, it is called a true cataract; but when it contact in front of the lens, it sists of opaque matter deposited in front of the lens, it is termed spurious. The latter arises from inflamis torned spurious. The latter arises from inflammation, and is to be treated by the usual means employed for allaying inflammation; but no operation can be of use in such a case. Of true caleract three kinds are distinguished;—lenticular, affecting the lens aloue; capsular, affecting the capsule; and capsulationing both lens and capsule. Lenticular cataracts are of two kinds,—hard and soft; ticular cataracts are of two kinds,—Aura and soft; the former being the more common, especially ameng elderly persons, and is usually of an amber-colour or brownish tint, and generally deep in proportion to its firmness. Soft oataract prevails in childhood and middle life, and occurs more frequently single than the other. A cataract may be occasioned by active inflammation or external violence, or it may be a compared to the common causes. Frequently arise from internal or unknown causes. Frequently it proceeds from an hereditary disposition which has existed for several successive generations, and some-times it attacks several members of the same family, without any evidence of its being hereditary. The habitual examination of minute objects in a depending position of the head, by which an undue proportion of blood is thrown upon the organ, is said irequently to bring on cataract. It may make its appearance at any age, but is most arequent in elderly persons, though children are by no means exempt from it, and may be even born with it. It comes on without pain, and the symptom first perceived is a dim haziness of sight, as if a mist or thin film were interposed between the object and the eye. The obscurity is greatest in direct vision, the opacity being almost always first noticed in the centre of the pupil. Hence the sight is better in a weak than in a strong light, because in the former case the pupil is enlarged, and admits the passage of the rays through the less opaque edge of the lens. Hence, too, the remarkable effect produced by the application of belladonna to the eye, which has the power of dilating the pupil and producing a temporary improvement in the sight,—a means sometimes bring on cataract. It may make its appearance at porary improvement in the sight,—s means contained had recourse to by quacks, who profess to be able to cure this disease. There is no medicinal remedy that cure this disease. There is no medicinal remedy that is known to have any effect upon this disease, nor is it at all likely, from the structure of the parts, that all likely, from the structure of the parts, that any such remedy exists. All palliative measures, therefore, are confined to attention to the general health of the patient and the removal of any inflammatory symptoms that may exist along with it. The only mode of care is actual removal by an operaonly mode of one is actual removal by an opera-tion; but so long as one eye remains unaffected, the operation may be delayed. There are three modes of operation employed for the removal of cataract, each of which has its advocates, and any one of which may be best, according to circumstances. The first is by extraction, or the removal of the lens, and is effected by making an incision through the cornea as near the iris as possible, and then, by means of a needle, opening the front of the capsule, and gently removing the lens. The second method is the displacement of the lens from the axis of vision by what is called outshing [Fr. outsher, to lie down) or depression. A needle is inserted through the fore part of the white of the eye, and is brought to bear upon the lens, pressing it back and down into the vitreous humour; and the opaque body being thus removed, sight is restored. The third

body being thus removed, sight is restored. The third method,—by absorption, is effected by uncturing the front of the capsule, and thus admitting the aqueous humour to act upon the cateract; by which means it is absorbed. All these operations require great care and skill in the operator, and the setting in of inflammation has to be specially guarded against.

Ezzette, e.e.e.ke.e.e (Heb., God strengthens), is the name of one of the canonical books of the Old Testament, placed after the book of Lamentations, and before that of Daniel. It is named after its author, Ezskiel, who was carried away by Nebuchadnezzar into Mesopotamia in the first Babylonish captivity, and is stated to have commenced his prophesying in and is stated to have commenced his prophesying in the fifth year of his captivity (about s.c. 59). The been at a book consists of forty-eight chapters, and naturally there are divides itself into two equal halves; the first contain-

# Ezra, Book of

ing oracles before the fall of Jerusalem; the last, oracles after that event,—the catastrophe in question forming the centre and culminating point of the book. In the first part we have (i) an account of Ezekiel's call to the prophetic office, his commission, instructions, and encouragements for performing the duties (i.—iii. 21); (2) a circumstantial announcement of the destruction coming upon Judah and Jerusalem, on account of the relative to the transmitted of the relative to the control of the relative to the relative the destruction coming upon Judah and Jerusalem, on account of the wickedness of the people (iii. 22-wii.);
(3) a cycle of visions and prophetic discourses, relating to the rejection of the covenant people, with a copious description of the guilt of the people, their rulers, priests, and false prophets (viii.—xix.); (5) several discourses reproving the idolatry of the people, and proclaiming the fearful judgment coming upon Jerusalem (xx.—xxiii.); (5) the destruction of Jerusalem and its inhabitants is figuratively delineated (xxiv.). The second part opens with prophecies salem and its inhabitants is figuratively delineated (xxiv.). The second part opens with prophecies against the Ammonites, Moabites, Edomites, and Philistines; (2) we have a prophecy against Tyre and Sidon (xxv.—xxviii.); (3) a prophecy against Tyre and (xxiv.—xxxiii.); (4) predictions respecting the restoration of the theorracy; (a) of the future salvation of Israel, in its conditions and basis (xxxiii.—xxxvi.); (b) in its development, from the reanimation of the people to their victory over all enemies of the Divine king. dom (xxvii.—xxiix.); (c) the renewal and glorifica-tion of the theoracy in the Massianic period (21.— xviii.).—(Horne's Introduction.) There are so few grounds for doubting the genuineness of this book, that its authenticity has been very little called in ques tion. Ezekiel seems to have been admirably fitted by natural disposition, as well as by spiritual endowments, to contend with the "rebellious house," the "people of stubborn front and hard heart," to whom he was of stubborn front and nard neart, to whom he was sent. With force, fire, and vehemence, he performs the functions of the prophetic office, throwing his whole soul into the work. He is deep, vehement, tragical; and the only sensation which he affects to excite is the terrible. "His sentiments are clevated, fervid, full of fire, indignation; his imagery is crowded, fervid, full of fire, indignation; his imagery is crowded, magnificent, terrific; his language is poupous, solemn, austere, rough, and at times unpolished, sometimes almost to disgust; he employs frequent repetitions, not for the sake of grace or elegance, but from the vehemence of passion and indignation. Whatever subject he treats of, that he sedulously pursues; from that he rarely departs, but cleaves, as it were, to it; whence the connection is, in general, evident and well preserved."—(Lowth.) The vigour and definiteness of his conceptions, down even to the minutest parts, is very marked. very marked.

very marked.

Eza, Book of, ez'-rū, stands next after the second book of Chronicles, and before the book of Nehemiah, among the canonical writings of the Old Testament. It has generally, both by Jews and Christians, been attributed to the priest whose name it bears; chiefly because, in ch. viii. and ix., the actions of Exra are related in the first person. It is a continuation of Jewish history, from the close of the book of Chronicles; giving an account of the post-exile history of that people; from their return out of captivity under Zerubbabel and Joshus till the arrival of Exra in Jerusalem. and the reformatory measures set on foot by salem, and the reformatory measures set on foot by him in the new colony. The events narrated in the hook occupy a period of about seventy-nine years (B.c. 538—457). It contains (1) the edict of Cyrus, permitting the Jews to return into Judæs and rebuild the mitting the Jews to return into Judges and rebuild the temple, with an account of the people who first returned under the leadership of Zerubbshesl, and of their offerings towards rebuilding the temple (i. ii.); (2) the building commenced (iii.); (3) hindrances from the Samaritans (iv.); (4) the temple finished in the sixth year of Darius Hystaspes, by the aid of a decree issued in the second year of his reign, and dedicated (v. vi.); (5) the departure of Ears from Babylon, with a commission from Artarerres Longimanus (vii.); (6) account of his companious, and arrival at Jerusalem (viii.); (7) narrative of the reformation effected by him (ix.x.). The book of Nehemiah is sometimes called the second book of Ezra, the two having been at one time connected together; besides which there are two specryphal books of that name. (Sce EBURAS.)

F.

F is the sixth letter and fourth consonant of the English alphabet, as it is also of the Latin. Its form is taken from the digamma of the ancient Greek alphabet, and it corresponds with the vau of the Hebrew. It is pronounced by bringing the upper teeth against the lower lip, and then breathing with a hissing sound. It is thus what is termed a labio-dental aspirate, and bears the same relation to the other labio-dental aspirate v that the unaspirated labials p and b bear to each other. F and v are frequently inter-changed, and in German v has the sound of f,—as von. sounded fon; hence, in English words taken from the German, ftakes the place of v. — as vater, father; vier, four. In Latin, f seems to have had a sound somewhat corresponding to a strongly-aspirated \( \hat{k}\); for we find the latter frequently substituted for the former in sind the latter frequently substituted for the former in the Sabine dialect of that language; and in Spanish, the Latin f is frequently changed into h,—as Latin for-mosus, beautiful; Spanish, hermoso. The phi in Greck was often in Latin represented by f instead of ph,—as pheme, fuma; and this is frequently done in Italian and Spanish,—as filosofia, philosophy. F in Latin also corresponded to the in Greck,—as Gr. ther. Lat. fera, a wild heart. Fin Latin and Grash often heavenet him wild beast. F in Latin and Greek often becomes & in English,—as frater, brother; and p in Latin and Greek, f in English,—as pater, father. F, in Mus., is the fourth note of the natural distonic scale. It is also used as an abbreviation for forte, strong or loud, the superlative fortissime being denoted by f.

superlative fortissimo being denoted by f.

Fans, fui-ba (from Gr. phago, I eut), in Bot., the
Bean, a gen. of the nat. ord. Leguminosæ, sub-ord.

Papilionaceæ. From the species f. vulgaris, formerly
regarded as Vicia fuba, all the cultivated varieties of
the broad bean have been produced. The earliest
garden variety is named the Mazagan, and the largest
the Windsor. Of the field bean there are two sorts,
the smaller being called ticks. Beans are largely used in feeding cattle, and are very nutritions. The garden beens form an important article of human food.

FABACEM, fui-bai'-se-e, a synonym for the nat. ord.

Leguminosa (which see).

ABIAN, fui'-be-un, an adjective expressive of delayelaying or dilatory. Its real acceptation is avoiding battle, in imitation of Q. Fabius Maximus, a Roman general, who, while conducting operations against Hamibal in one of the Punic wars, only kept on harassing Hamibal by ambuscades and forays, without giving the Carthaginian general an opportunity of open battle. It thus is read to avoid the conductive or dilators conduct.

It thus is used to express delay or dilatory conduct.

FABLE, fui'bl (Lat. fabula), denotes, in its most general sense, any fictitious narrative; but more particularly it is a short fictitious story, intended to convey practical rules of worldly prudence or wisdom, by imaginary representations drawn from the physical or external world. It differs from a parable, with which it has many features in common, in being carried which it has many features in common, in being carried beyond the bounds of the probable, and even of the possible. In the Esopean fable, the imagined actors, or the chief of them, instead of being men, are the lower animals, and sometimes even plants, or other things really inanimate. The fable consists, properly, of two parts,—the symbolical representation and the application, or the instruction intended to be deduced from it, which latter is called the moral of the tale; that it caucht also to be avanced in the fable itself in but it ought also to be apparent in the fable itself, in order to render it complete. On account of its aim, it order to render it complete. On account of its aim, it lies upon the borders of poetry and prose. By its very impossibility, the fable awakens and arrests the attention, and thus the meaning that is intended to be conveyed is made the more apparent. The oldest fables are believed to belong to the East; and of these the most celebrated are the Indian fables of Pilipay, or Bilpai; and the more meagre Arabic collection attributed to Lokman, who is said to have lived in the time of king David. Among the Greeks, the fables of Reop are well known; but not a few of those that were current in Greece under his name are identical with those of the East. In Latin, Phedrus has left about hinety fables of considerable merit in imitation of Reop; but the well-known fables of "the town mouse

and country mouse," related by Horsee, is the best in that language. During the middle ages, the fable does not seem to have been entirely neglected; and an edition of those current in Germany in the time of the edition of those current in Germany in the time of the Minnesingers has been published by Bodmes. The oldest known writer of fables in Germany is Stricker, who flourished about the middle of the 13th century; and among the most distinguished of the later writers of that country are Gellert, Gleim, and Lessing. In England, the most distinguished name in this walk is John Guy; and in France, pre-eminent among all the moderns for his delicate sarcasm and lively wit, is La Fontaine.

FACADE, fas-sade' (Fr.), in Arch., a term used to express the face or front of any building of importance. It may be applied to any side of a large quadrangular building embellished with sufficiently striking architectural features, but it is usually confined to the principal front, in which the chief entrance is most frequently, if not always, situated.

Face, fais (Fr. face, Lat. facies, Ital. faccia), in Cryst, the terminal planes of a regular solid: thus

the cube has six faces, or flat surfaces.

FACE. (See PHYSIGGEOM.)

FACE., fw.-set, in Min., a term applied to the small faces of a gum or crystal. When precious stones are cut with numerous faces, they are said to be facetted, in contradistinction to those polished into rounded

forms or cut en cabochon.

FACIA, fai'-she-ā (Lat. facies, a face), in Arch., a name often given to flat bands or fillets introduced into architectural embellishments, but more frequently applied to the bands of an architrave, which are so placed that the one above projects beyond the surface of that which is immediately below it. In the archi-trave of the Composite order of architecture two facias are generally used, while in the Corinthian, and some-times in the Ionic order, three are introduced. A pictorial representation of the facia will be found in the engraving illustrating the article ENTABLATURE.

(See ENTABLATUBE.)
FACIAL ANGLE. (See ETHNOLOGY.)

FAC-SIMILE, fik-sim'-e-le (Lat., from facio, I make, and similis, like), denotes an exact initiation of an original in all its traits and peculiarities, a copy as accurate as possible. It is chiefly used in relation to copies of old manuscripts, or of the handwriting of famous men, or of interesting documents, which are

rande men, or of interesting documents, when are made by engraving or lithography.

Faction, fak'-shun (Lat. factio), is a term applied in a bad senso to any party in a state that offers uncompromising opposition to the measures of the government, or that endeavours to excite public dis-

content upon unreasonable grounds.

FACTOR. (See AGENT.)
FACTOR, fak-tor (Lat. facere, to form), in Alg. and
Arith., a term applied to each of the quantities which are multiplied into one another; in other words, to the are multiplied into one another; in other words, to the multiplicand and the multiplier, in order to form a product. The term factor is also used in the same sense as divisor; so that any quantity that will divide another is a factor of it. The entire factors of 12 are 1, 2, 3, 4, and 6. Taken in pairs, the factors are 1×12, 2×6, 3×4, &c. The prime factors of a quantity are those factors which cannot be exactly divided by any other quantity except 1. Every number has 1 for a prime factor.

prime factor. Factors, fik'-to-re, in a general sense, any building where cotton, wool, silk, flax, hair, henre, jute, or tow, are manufactured by machinery worked by steam, water, or some other power. The factory system, at it is called, dates from the introduction of Arkwright's it is called, dates from the introduction of Arkwright's spinning machinery. After that time large numbers of workmen met together at the new cotton-mills. It is in this branch of manufacture that the factory system has been most developed. The advantages gained, are the subdivision of labour according to skill and strength, and that of applying to each process exactly the farce that is necessary. Up to the year 1833, the employment of children in factories was much abused; they were employed by workmen whose wages depended greatly upon juvenile labour, and who consequently overtasked their strength and permanently injured their constitutions. A parliamentary committee investigated this subject in 1832; and a committee investigated this subject in 1832; and a

### Factory Acts

mission was appointed to examine the mills themselves. mission was appointed to examine the mills themselves. An act for regulating factories was passed the next year. (See Facrosz Acrs.) In North America, spinning and weaving factories are much more frequently owned by joint-stock companies than in England. Some of them are very large, and the workmen and work-women hold a higher social position than in England. Many of the factories have boarding-houses attached to them, in which many of the operatives. attached to them, in which many of the operatives, especially young women and girls away from home, are boarded and lodged under a well-conducted system. The word factory was first applied to large aggregations of workpeople in one building during Arkwright's time. At that period it signified an establishment of merchants and factors in foreign countries. These factories were governed by several rules adopted for their own support, and in order to protect them from the interference of the governments of the countries in which they resided. In modern times these factories have rly ceased to exist. The mode in which they were instituted seems to have been, that they first had a liberty to trade, then a district was assigned to them, in which they were exempt from the jurisdiction of the native courts. The English, at an early period, formed factories in China, which still exist. Factories have also been established by the Venetians, Genoese, Por-

tuguese, Dutch, and French. ACTORY ACTS are certain acts of parliament, which have been passed from time to time, regulating the employment of labour in these establishments. In 1832, in consequence of the numerous complaints that were made regarding the injurious effects of factory labour on the health of the labourers, particularly the young employed in them, a parliamentary committee was appointed to investigate the subject; and subsequently a commission was named to inquire on the spot into the actual condition of the operatives. At-tempts had previously been made in 1802, 1816, and 1831, to legislate on the subject; but only on a small scale. In consequence of the report of the commission, 3 & 4 Will. IV. c. 103 (1983), was passed, declaring, that after January 1, 1834, no person under 18 years of age shall be allowed to work in the night (i. e. between 8.30 p.m. and 5.30 a.m.) in any cotton or other factory, excepting in lace factories; that no person under 18 shall be employed more than 12 hours in one day, or 69 hours in one week; that 1½ hour daily be allowed for meals to each person restricted to 12 hours work; that no child shall be employed, except in silk-mills, under nine years of age; that after March 1, 1834, no child under 11 years old shall be employed in any factory, except in silk-mills, more than 48 hours in any one week, nor more than sine hours in any day,—nor after March 1, 1835, who shall not be 12 years old,—nor after March 1, 1836, who shall not be 13 years old; that children and young persons, whose hours of work are regulated, shall be entitled to two holidays and eight half-holidays shall be entitled to two noncays and eight nationarys in every year; that children, whose hours of work are restricted to nine hours a day, are not to be employed without a certificate from a physician or surgeon, certifying that they are of the ordinary strength and appearance of children of these ages; the crown to appoint four inspectors, with extensive powers, to see that the various provisions of the act are carried out. to make rules necessary for its execution, and to enforce attendance at school, for at least two hours daily out of six days in the week, of children employed in the factories. The following year, a short explana-tory act was passed; but nothing further was done till 1844, when 7 & 8 Vict. c. 15, became law. By this act, the powers and duties of inspectors are more accurately set forth; and an office of factory-inspec-tors is established in London; regulations are laid down for the protection of children in wet-flax spinning, and from accidents by the machinery while in motion: a child is defined to mean a person under 13, and a young person, one between the ages of 13 and 18; children may be employed at eight years of age; all 18; children may be employed at signt years of age; au mount of daily work for each child is seven hours; work for children and young persons is to cease on Saturday at half-past four; and certain provisions are made regarding the meal-times. By 10 Vict. c. 29, the hours of labour for young persons, and women

# Fagus

above 19, are reduced to 11 hours a day, after July 1, 1847, and 10 hours after May 1, 1848; and by 16 & 17 Vict. c. 102, children are not to be employed before six in the morning, or after six in the evening, or after two on Saturday. In 1856, an act was passed as to mill-gearing, limiting the fencing to such parts of the machinery as children and young persons are liable to be injured by.

FACULTIES, COURT OF, fük-ul-ties, a court established by 25 Henry VIII. c. 21, under the archbishop of Canterbury, and having power to grant faculties, privileges, indulgences, dispensations, licenses, and the like, connected with ecclesiastical matters. Now the business of the court is chiefly confined to grant-

ing licenses to marry.

FACULTY, fük'-ul-te (Lat. facultas), in Phil., is commonly applied to those active powers of the mind which are original and natural, and which make part of the constitution of the mind. Capacity, on the other hand, is applied to those manifestations of mind other nand, is applied to those manifestations of mind in which it is generally regarded as passive, as affected or acted upon by something external to itself. "Powers natural and active," says Sir W. Hamilton, "are called faculties. Powers natural and passive, capacities or receptivities. Powers acquired are habits, and habit is used both in an active and passive sense. The power again of soquiring a habit is called a disposition." When philosophers thus classife the sense. The power again of acquiring a maniferance and adaposition." When philosophers thus classify the different operations of the mind, and assign them to different powers, it is not to be supposed that they regard the mind as made up of so many distinct parts. The mind manifests itself in different ways, and it is only these manifestations that they arrange and classify. When, therefore, they speak of a power or faculty of the mind, they only mean that certain operations the mind have been observed and classified, according to the conditions and circumstances under which they manifest themselves. "This way of speaking of facul-ties," says Lucke, "has misled many into a confused notion of so many distinct agents in us, which had their several provinces and authorities, and did command, obey, and perform several actions, as so many distinct beings: which has been no small occasion of wrangling, obscurity, and uncertainty, in questions relating to them."

relating to them."

FACULTY, in a university, is one of the particular departments of teaching. In most universities there are four faculties; viz. arts, law, medicine, and theology. (See UNIVERSITIES.)

FAGGING, fäg'-ging (Ang.-Sax.), is a term applied to a system of servitude which was at one time general in the higher sobools of this country, and which has not yet entirely disappeared. It consists in the junior boys, or those of the lower school, as it is called, being compelled to act as servants or "fags" to the older or more advanced pupils. The fag is under entire subjection to his master, having to attend to his fire, prepare his meals, brush his clothes, and perform other menial duties. Several attempts have of late vears menial duties. Several attempts have of late years been made to abolish this barbarous custom, and it is hoped that it will soon entirely disappear.

FAGGOT, or FAGOT, füg-got (Fr. fagot, Armoric and Welsh fagod), is generally a bundle of sticks or small branches of trees bound together. In times of religious persecution the faggot was a badge worn on the sleeve of the upper garment of such persons as had ab-jured heresy, being put on after the person had pub-licly carried a faggot to some appointed place by way of penance. To leave off the wearing of this badge sometimes regarded as a sign of spostasy. Among military men faggots were persons hired by officers whose companies were not full, to muster and hide the deficiencies of the company, and thus cheat the government of so much money. Faggot votes, in politics, were votes created by the partitioning of an estate into numerous small tenements, which were let to persons at an almost nominal rent, upon condition of voting at elections according to the dictates of the lessor.

FAGOPYRUM, fai-go-pi'-rum, in Bot., the Buckwheat, a gen. of Polygonaces. The fruits of F. esculentum and tataricum are used as a substitute for corn in the north of Asis and eastern Europe. The former species is outlivated in Britain as food for pheasants.

FACUS, fai-gus (from Gr. phage, I eat), in Bot., the Beech, a gen. of the nat. ord. Corplaces. F. sylvation,

### Fahrenheit's Thermometer-Scale

the common beech, is one of our noblest forest trees This and F. americans are much valued for their timber. The fruits (beech-mast) form a food for pigs. The fruit of F. ferrugines is eaten in North America for dessert.

FARRENHEIT'S THERMOMETER-SCALE, (See THER MOMETER.)

FAINTING, or SYNCOPE, faint'-ing, sin'-kope (Irish faine, a weakening; Gr., from sun, with, and kopto, I iall down), in Pathol., is a sudden and total or partial unconsciousness, resulting from impaired circulation of the blood through the brain, occasioned commonly by diminished action of the heart. The functions of the nervous system, respiration, and the action of the heart, are either suspended or very much diminished in strong mental emotion, loss of blood, severe pain, or anything which tends to diminish the vital energy of the system. Usually the patient is first conscious of a singing in the ears, then the sight becomes confused and all the senses deadened; the countenance becomes and an the series feathered; the contensate becomes deadly pale, and the limbs are unable to support the weight of the body, which sinks to the carth. Fainting, if occasioned by a diseased state of the brain or heart, or if prolonged, may result in death; but if arising from any trivial cause, the patient in general speedily recovers. The patient should be laid on his back with his head low and his dress located about back, with his head low, and his dress loosened about the neck; abundance of fresh air should be admitted

to him, and cold water may be sprinkled on his face and neck, or ammonia applied to the nostrils. Fals, fair (Fr. foire, Welsh fair, Lat. forum, a market-place), is a larger species of market, which is held at more distant intervals, and sometimes devoted to one species of merchandise, sometimes to several. In the earlier stages of society, and in inland countries where the facilities for commerce are comparatively circumscribed, the bringing together of commodities and dealers at certain times and in convenient places is of the utmost importance; and for this purpose various privileges have been annexed to fairs, and numerous facilities afforded for the disposal of pro-perty in them. In this country no fair can be held without a grant from the crown, or a prescription which supposes such grant; and before a patent is granted, it is usual to have a writ of ad quod damnum executed and returned, that it may not be issued to the prejudice of a similar establishment already existing. If her Majesty grant power to hold a fair or market in a particular place, the lieges can resort to no other, even though it should be inconvenient; but if no place be appointed, then the grantees may hold it where they find it to be most convenient. Formerly courts were established in connection with fairs, commonly called pie poudre, in allusion to the dusty feet of the suitors, where summary judgment was administered on all matters of dispute arising from transactions at the fair. In this country the fairs have lost much of their ancient In this country the tairs have lost much of their ancient splendour, and many of them have all but disappeared. The growth of towns, and the facilities afforded for the disposal and purchase of all kinds of produce, have rendered them much less uccessary now than formerly. Those that are chiefly of use in the present day, and which have least declined, are the cattle and horse The August fair of Hornoastle, in Lincolnshire, is the largest horse fair in the kingdom, many thousand is the largest horse fair in the kingdom, many thousand horses being exhibited for sale at it. St. Faith's, near Norwich (Oct. 17), is the principal English fair for Scotch esttle; and Weyhill fair, in Hampshire (Oct. 10), has probably the greatest display of sheep of any fair in the kingdom. Falkirk fair or tryst is one of the most important in Scotland for the sale of cattle and sheep; and hardly inferior to it are those of McIrose and Lockerly. In Germany, the principal fairs are those of Leipsic, Frankfort-on-the-Maine, and Frank-fort-on-the-Oder. In France, that of Beaucaire was fort-on-the-Oder. In France, that of Beaucaire was formerly the largest in Europe, and is still frequented by a vast concourse of people. The great fair of Nishnij-Novgorod, in Russis, is at present the most important in Europe, being frequented by buyers and sellers from different parts of Europe and Northern and Central Asia. Another celebrated Russian fair is that of Kinchta, on the Chinese frontier, where the greater part of the commerce between the Chinese and Russian empires is transacted. A large fair is held at

Mecca during the resort of pilgrims to that place.— Ref. McCulloch's Commercial Dictionary.

FAIRIES, or ELUES, fair'ees, elvz (Ger. elfe, Sw. elf, Dan. ellefolk, Old Norse alf), are supernatural beings, Dan. etteroth, the Norse act /, are supernatural senge, of human shape, of both seres, and generally of very diminutive size. The name fairy is derived from the Latin fatum, fate; and hence the Italian name of this class of beings is fata. Elf is derived from the Old Norse alp, or alf, which signifies both a mountain and a demon of the mountains. The Anglo-Saxoss had their dun-actionne, or fairies of the mountains; wuldactions, or fairies of the woods; water-actions, or fairies of the fountains. They are thus classed by Shakspeare :-

Ye elves of hills, brooks, standing lakes, and groves, And ye that on the sands with printless foot Do chase the ebbing Neptune, and do fiee him When he comes back."—Tempest, act v. sc. 1.

The general belief is that the native land of fairy mythology is Arabia, and that our knowledge of these beings was brought from that country by the Crusaders; but there can be no doubt that their origin is much more sucient. They are generally believed to be a kind of intermediate beings, partaking both of the na-ture of men and spirits, having material bodies, and yet possessed of the power of making themselves invisible, and of passing through any sort of inclosure. They are remarkably small in stature, with fair com-plexions, and generally clothed in green. Their hunts were believed to be groves, verdant meadows, and the slopes of hills, and their great diversion dancing handin-hand in a circle, as alluded to in Midsummer Night's Dreum. The traces of their tiny feet are supposed to remain visible in the grass long afterwards, and are called Fairy Rings or Circles (which see). They were regarded as of a doubtful character, being sometimes benevolent and sometimes mischievous. The diseases of cattle were frequently attributed to their mischievous operation; and cattle that died suddenly, without any apparent cause, were commonly said to be elf-shot. They were said to be very fond of human children, and They were said to be very fond of human children, and were in the habit of carrying away such as they could lay hold of, and leave vixens of their own in their room. In Poole's "Parnassus" are given the names of the fairy court:—"Oberon, the emperor; Mab, the empress; Perriwiggin, Perriwinele, Puck, Hobooblin, Tomalin, Tom Thumb. courtiers; Hop, Mop Frop, Pip, Drip, Skip, Tub, Tib, Tick, Pink, Pin, Quick, Gill, Im, Tit, Wap, Win, Nit, the maids of honour; Nymphidia, the mother of the maids." T. Crofton Croker, in his "Fairy Legends and Traditions of the South of Ireland," describes them as beings "a few inches high, airy, and almost transparent in body; so delicate land, describes them as beings "a few inches high, airy, and almost transparent in body; so delicate in their form, that a dewdrop, when they chance to dance on it, trembles, indeed, but never breaks. Both series are of extraordinary beauty, and mortal beings cannot be compared with them." They live in large cannot be compared with them. cannot be compared with them." They live in large societies, and are governed by a queen; and the peasantry never speak of them but with caution and respect, as the good people and friends, believing them to be present, and to hear what is said. They have their dwellings in clefts of rocks, caves, and ancient tumuli, and every part of them is decorated in the most splendid and gorgeous manner. The popular belief in fairies may now be said to have died out in this country; but it it was are indebted for a class of this country; but to it we are indebted for a class of literature which, at least to the young, has its cease-less charms. The true fairy tales first became popular in the latter part of the 17th century, and the Italians appear to have been the first to take the lead. After a time, they became very popular in France; and, at present, they are more extensive and popular in Germany than in any other country.

FAIRY RING OF CIRCLE, is a ring occasionally observed in pastures, and which was usually attributed by the peasantry to the daucing of the fairies. They are seldom of a perfect form, but are usually more or less irregular, sometimes forming a series of area of circles. They were ascribed by scientific men to various causes; but they are now known to be occasioned by the growth of certain kinds of fungi, which, proceeding outwards from a centre, render the soil for a time unfitted for the nourishment of grass.

FAITH, faith (Lat. fides), is that assent or credence

Fall of Bodies

which we give to the declaration or promise of another, on the authority of the person who makes it. The greater part of our knowledge is derived from the information of others, and depends upon the credence which we give to their testimony; hence, to believe and to know are sometimes used indiscriminately. Bath is the person by which we obtain a knowledge of Faith is the means by which we obtain a knowledge of things which do not come under our own observation, things not seen; and in this way faith is distinguished from sight. Faith is also distinct from reason, in so far as it deals with matters which we cannot comprehend by our reason; but, at the same time, while we exercise faith, we must also exercise reason; for it is impossible to exercise an acceptable faith without reason for so exercising it. Henry Rogers represents "reason and faith as twin-born; the one, in form and features, the image of manly beauty, the other of feminine grace and gentleness, but to each of whom, alas! is allotted a sad privation. While the bright eyes of Rosers are full of represent and restless intelligence. of Reason are full of piercing and restless intelligence, his ear is closed to sound; and while Faith has an ear of exquisite delicacy, on her sightless orbs, as she lifts them towards heaven, the sunbeam plays in vain. Hand-in-hand the brother and sister, in all mutual love, pursue their way through a world on which, like ours, day breaks and night falls alternate; by day the eyes of Reason are the guide of Faith, and by night the ear of Faith is the guide of Reason." "Reason is apt ear of Faith is the guide of Reason." "Reason is apt to be eager, impetuous, impatient of that instruction which his infirmity will not permit him readily to apprehend; while Faith, gentle and docile, is ever willing to listen to the voice by which alone truth and wisdom can effectually reach her." (Essay on Reason and Faith.) Faith, in Theol, denotes the assent of the mind to the truth of what has been revealed to us to the All-Serietteen reasonability that living in the Holy Scriptures, more particularly that living reception of truth by the heart by which we see our sinfulness in the sight of God, and are led to flee to sinfulness in the sight of God, and are led to flee to Christ for salvation. Some theologians distinguish four kinds of faith:—(1) A mere assent to the truth of the doctrines of the Gospel, which leaves the heart numoved and unaffected; (2) a belief in the doctrines of Christianity, coupled with a sense of our lost and sinful condition; (3) the assent of the mind, also, to the means of man's justification in the sight of God; and (4) such a belief us, by the aid of the Holy Spirit, leads us to come to Christ, and place all our hopes in him for salvation, which alone is the "saving faith." There was also in the early church that miraculous faith by which the apostles and others were able to faith by which the apostles and others were able to work miracles.

FARIR, fa-keer' (Arab., poor), a term applied to asceites in several parts of the Eastern world, particularly in India, and is synonymous with the Fersian and Turkish dervish (which see). Some of them live in communities, like the monks of the Western world, while others live singly, as hermits, or wander about, making strange displays of self-torture and mortificamaking strange displays of self-torture and mortifications. Their appearance is flithy and disgusting in the
extreme. They go about naked, frequently with their
bodies besmeared with the dung of the holy cow. They
sometimes unite in bands, carrying banners, and
making a great noise with drums and horns. Some of
them hold their arms up in one position for years,
till they have lost the power of taking them down
again; others bend the body forward, till they are
mable to restore it to its natural position again; while
others cleuch their fists till the nails grow through the
hand. They usually take up their abode in shady
places, either in the open air or in old and ruinous
buildings, without anything to repose on or to cover
themselves. One writer affirms that a member of this
order should have ten of the qualities proper to the
dog; among which are, to be always hungry; to have
no fixed residence; to watch during the night; to leave
no fixed residence; to watch during the night; to leave
no heritage after his death; not to abandon his master,
although ill-treated by him; to content himself with athough ill-treated by him; to content himself with the lowest place, and to yield his seat to any one who wants it. It is estimated that there are not less than three millions of fakirs in India. Many of them are undoubtedly insane; but the greater part of them are

the existence of a slight festoon on the lateral margin of the upper mandible, and also of an acute tooth on each side towards the apex. The wings are very long and pointed, the second and third quills being the longest; the tail is long and rounded; the tarsi of moderate length, stout and reticulated; the toes usually clongated, and terminated by long curved and acute claws. The tongue is fleshy, sloped, and canaliculated. The falcons proper are distinguished from the gerfalcon by a tooth more strongly defined on each side of the upper mandible, which, among the others, is a mere festoon; the lower mandible is also much more sloped at its point than in the true falcon. The falcons are found in all parts of the world, and the number of species is very large. Their flight is very swift, and their courage certainly greater than that of other rapacious birds. Their flight is performed by regular continuous beats, with little or none of that saling motion which characterizes the kites. In capturing their prey, whether in the air or on the ground, they descend perpendicularly upon it. Their food consists, for the most part, of small quadrupeds and birds; but many of them also feed partly on reptiles and insects. The nests of these birds are rough and bulky, composed of sticks and twigs placed in the hollows of rocks or in trees. The eggs are usually laid at the close of winter or very early in spring; they vary in number from three to six, and are generally speckled with red or brown. (See GEE-FALCON, GORNAWES, &c.)

FALCORY. (See CHEVALOON, GORAWAR, &C.)
FALL OF BODIES, faul (Ang.-Sax.).—When a body is allowed to drop through the sir from a great height, or is thrown upwards, or through the air in any direction, the course which it takes, and the rapidity of its motion from or towards the earth, is regulated in all motion from or towards the earth, is regulated in an eases by certain laws. The motion of a body projected through the air in a horizontal or oblique direction, and the path which it describes, are considered elsewhere (see PROJECTILES, THEORY OF); and it will be sufficient here to examine the rate of motion of a body moving towards or from the earth in a vertical line. If a person were to stand on the top of a very high to the earth, moving much more rapidly as it approached the ground than it did when it was first dropped from the hand at the top of the tower. Its motion downwards is found to be what is termed a uniformly accelerated when it was first dropped from the hand at the top of the tower. Its motion downwards is found to be what is termed a uniformly accelerated writing the state of th formly accelerated motion; that is to say, a motion continually increasing at a certain rate; or, in other words, if a body be moving at a certain velocity at the expiration of one second from the point of time at which it was allowed to fall, it will be moving twice as fast at the expiration of two seconds, three times as fast at the end of three, and so on. Experiments have shown that the rate per second at which bodies acquire velocity if moving downwards through the air, or lose velocity if moving upwards, is 321 feet. (See GRAVITA-TION, PENDULUM.) This velocity acquired by a falling body in a second of time is called the measure of the body in a second of time is called the measure of the accelerating force, which force is produced by the attraction of the earth. Therefore, when a ball has been allowed to fall from the top of a tower, it is moving at the rate of 32½ feet per second at the end of the first second after it has been dropped from the hand; at the end of the next second, it is moving with a velocity of 64½ feet per second; and so on. It will be seen, therefore, that the velocity of a body at any period of its fall may be ascertained by multiplying the rate of motion at the end of the first second, or, as it is generally called, the measure of the accelerating force, by rally called, the measure of the accelerating force, by the number of seconds during which it has been falling. The velocity of a body at any period of its fall being known, the space or length through which it has fallen may be ascertained by multiplying the velocity at that period by the number of seconds during which it has een falling, and dividing the result by 2. Thus, if a been taking, and dividing the result by 2. Lus, it is body has been falling from a state of rest for 5 seconds, its velocity at the end of the fifth second will be  $32\frac{1}{8} \times 5$  =  $160\frac{1}{9}$  feet per second; and the space through which it has fallen will be  $100\frac{1}{8} \times 5 + 2 = 402\frac{1}{19}$  feet. If a body be thrown from the hand with considerable force, in impostors and hypocrites.

EALCON. (See FALCONIDE.)

FALCONIDE., fül-kon'i-de.—Birds of this genus are its velocity at any period of its course will be found by distinguished from all other members of the family by adding the rate of motion that it would have attained

at the end of any number of seconds, if allowed to fall from a state of rest to the initial velocity imparted to the body at the moment when it was faunched from the hand. Thus, in the example above given, if the body had been thrown downwards with an initial velocity of had been thrown downwards with an initial velocity of 50 feet per second, its rate of motion at the end of the fifth second would be 50+180% =210% feet; but the space through which it has fallen would be 50×5+402% =652% feet, as the initial velocity of 50 feet per second tends to carry it through 250 feet in the five seconds in addition to the space through which it is conveyed by the accelerating force of the earth's attraction. In the same way, if a bail be thrown upwards into the air at a certain velocity, by a person standing on the earth's surface, its motion will become slower and slower, at the rate of 321 feet per second, until the force with which it has been propelled upwards is entirely counteracted and destroyed by the attraction of the earth, which now acts as a retarding force; and when its initial velocity has been thus exhausted, the ball will seem to be stationary for a very small fraction of time, and then descend, acquiring rapidity of motion at the same rate as a ball allowed to fall from the same height from a state of rest.

FALLACY, fáll-lá-se (Lat. fallacia), in Log., is defined by Whately to be "any argument, or apparent argument, which professes to be decisive of the matter at issue, while, in reality, it is not." Fallacies are com-monly divided into two classes. monly divided into two classes, according as the error lies in the words of the reasoning (in dictions) or in the matter (extra dictionem). The former are otherwise describable as formal, or logical fallacies; the latter as material, or non-logical fullacies, as errors arising beyond the reasoning process. They may be otherwise distributed into three classes,—fallacies of assumption, fallacies of exposition, and fallacies of inference; the first two being fallacies extra dictionem, the last in dictione. The fallacy of assumption consists in our reasoning from premises which are either untrue in themselves, or not admitted by those whom we wish to convince; as in begging the question when we take a thing for granted which requires to be proved, and in reasoning in a circle. A fallacy of exposition consists essentially in a mis-statement or wrong exposition of the question argued. This fallacy is committed when the conclusion which we infer, although it may legitimately be deduced from premises true or admitted, is not the conclusion which we are bound to prove,—it is not to the point, or away from the question. It is called in Latin ignoratio elenchi, because it is not the "elenchus" (i. s. proof of the contradictory of your opponent's assertion), which it should be. The varieties of this form of error are very numerous. Fallacies of inference are all in dictione,—formal or logical fullacies. In this class, the conclusion which the argument is supposed or alleged to prove does not follow from the premises. Fallacies of inference arise from illicit process either of the major or minor term, non-distribution of the middle term, or the occurrence of more terms than three. Fallacies of inference are otherwise divided into purely logical fallacies, or such as appear on the face of the argument, and semi-logical fallacies, those which are not apparent until we have ascertained the meaning of the term in which it occurs. All semilogical fallacies of inference are referable to one cause,—ambiguity of terms. (See Logic.)—Ref. Encyclopadia Britannica.

FALLING SIZKNESS. (See EPILEPSY.)

FALLING STARS, fawl ing, meteoric bodies, supposed to be of a similar nature to serolites. (See Arrolite.) They appear to the observer to resemble stars sud-denly falling from their position in the heavens, and vanishing after a flight of short duration, during which ransanng ster a light of short duration, during which they seem to draw a brilliant train of light behind them. The diameter of these bodies is supposed to vary from 80 to 120 feet, and their rate of motion to be between 20 and 40 miles per second; their distance from the earth, when visible to the beholder as falling stars, is considered to range between 20 and 150 miles, beyond which limit they become invisible. They generally appear singly, but sometimes in great numbers, almost resembling a shower of fire, a flight of many thousands having been noticed by Professor Olmsted in North America on the night of the 12th of November, 1833. It is been ascertained, by a long series of observa-

tions, that this phenomenon occurs with regularity at certain seasons of the year, particularly in the latter part of the months of April and November. It is also supposed that they occur with greater brilliancy at intervals of about thirty-four years, Humboldt having observed a remarkable fall of shooting stars at Cumana, in South America, in November, 1799, thirty-four years prior to the occurrence of the brilliant flight noticed by Olmsted in 1833. If this be the case, the next ex-traordinary display of fulling stars will take place in November, 1867.

FALLOPIAN TUBES, fal-lo'-pe-an, in Anat., so called after the anatomist by whom they were first described, are slender tortuous canals, about four inches in length, proceeding from the upper angle of the uterus. inner, or attached extremity, is narrow and cordlike; but they soon begin to enlarge as they proceed outwards, and at length they bend backwards and downwards towards the ovary, about an inch beyond which they terminate in an expanded extremity, the margin of which presents a number of irregular processes, named fimbric, one of which, somewhat larger than the rest, is attached to the outer end of the corresponding overy. They serve as ducts of the overies.

FALLOW, fall-lo (Ang.-Sax.), in Agr., a term applied to a portion of ground in which no seed is sown for the space of a year. This is done in order that the soil may be exposed to the action of the atmosphere, son may be exposed to the adiable of the armsphere, the weeds destroyed by repeated ploughings and harrowings, and fertility restored, which previous crops had exhausted. A green fallow is a term applied to land which has been rendered mellow and clean from weeds, by means of some green crop, such as turnips, potatoes, &c.

Fallow DREE (Cervus Dama). - This kanimal may be distinguished from the stag by the spotted coat, the spread and palmated horns, and the smaller size. It seldom measures more than three feet high size. It sends at the shoulder. Its colour is reddish proven, apparent with white; but there is a variety which is of a nearly uniform dark brown. This latter is a native of a state of the time of the state of the time of the state of the uniform dark brown. This latter is a native of Norway, and was brought to England at the time of James I. The manners of the fallow deer resemble those of the stag; but it is less delicate in the choice of its food, and browses closer. It attains full growth at the age of three years, and is said to live twenty years. The fallow deer's native country is the south of Europe and the south-western part of Asia. The skin of this animal furnishes a valuable leather, and the horns, like those of the stag, are manufactured into knife-handles, &c. The shaving of the horns has been used in the manufacture of ammonia, popularly known as hartshorn. (See Deer.)
False Imprisonment, fawlee (Lat. fulsus).-

confinement of the person is an imprisonment, whether it be in a common prison, in a private house, or even by forcibly detaining one in the public streets. lawful or false imprisonment, then, is when such confluement takes place without sufficient authority. A person who falsely imprisons another is liable to a criminal prosecution, and also a civil action for damages.

FALSE NEWS .- The spreading of false news, to make discord between the king and nobility, or concerning any great man of the realm, is a misdemeanor, and punishable by common law with fine and imprisonment.

FALSE PRETENCES, THE OBTAINING MONEY UNDER, in Law, is provided for by 7 & 8 Geo. 1V. c. 29, which enacts, that if any person shall, by any false pretence, obtain from any other person, any chattel, money, or valuable security, with intent to cheat or defraud any person of the same, he shall be guilty of a misdemea-nor, and liable to transportation for seven years (now penal servitude), or to fine and imprisonment. Act 14 & 15 Vict. c. 100, provides that it shall be no bar to conviction, that such erime may amount in law to larceny; and that it shall be sufficient to prove that the defendant did the act with intent to defraud, without specifying any particular person.

FALSE SWEADING. (See PERJURY.)
FALSE WEIGHTS AND MEASURES. (See WRIGHTS

AND MEASURES.)

FALSETTO, fuwl-set'-to, an Italian word used in Mua.
to signify a feigued or artificial voice, produced by
diminishing the aperture of the throat. The Italians

#### Fama Clamosa

call the falsetto, voce di testa, or voice from the head, in contradistinction to voce di petto, the natural or

chest voice.

Fama Clamosa, fai'-mä kläm-o'-sā (Lat.), in the
Eccl. Law of Scotland, is a wide-spread report affecting the moral character of a clergyman or elder of the
church, and which may be taken up and investigated
by the church courts, independently of any regular
complaint by a particular accuser.

Familia Spirits, fām-l'-yār (from Lat. familia),
a name given to certain demons or evil spirits, which
were supposed to attend and be at the service of a

were supposed to attend and be at the service of a magician, or other favoured person. The belief in familiar spirits is very sacient, and by the law of Moses, such as had familiar spirits were to be put to death. Where Socrates speaks of his attendant demon, he is generally understood to refer to the inner feelings and promptings of his nature, and not to any familiar spirit. In eastern countries, the belief in familiar spirits is very general; and it was widely diffused over Europe in the middle ages. A favourite form assumed by a familiar spirit was that of a black dog. Jovius says that Cornelius Agripps was always accompanied by a devil in the form of a black dog; and Goethe makes Mephistopheles first appear to Faust in this shape. Paracelsus was believed to carry about with him a familiar spirit in the hilt of his sword.

FAMILIAES, fam-il'-yars (from Lat. familia, a family, as belonging to the family of the inquisitor), the name given to certain officers of the Inquisition, who assisted in apprehending such as were accused, and carrying them to prison. This office was esteemed so honourable that even noblemen and princes were ambitious of being admitted to it,-even the king of Spain himself assuming that title, and becoming protector of the order. Familiars were granted large indulgences and privileges, and might commit the most heinous crimes with impunity.

FAMILY, fam'-e-le (Lat. familia, Gr. oikos), is applied in a general sense to a number of individuals living together, or standing in a certain degree of relationship to each other; a household, including parents, children, and servants; or all descended from one common progenitor. Among the Romans, familia was applied to all persons in the power of a paterfumilias, applied to all persons in the power of a pater diminus,
—as his sons, daughters, grandchildren, and slaves;
but it was also used in a wider sense, including all objects of property, even inanimate, and is explained by
Gaius by the equivalent patrimonium. The family is
the corner-stone of the social edifice, and is well said
to be "God's best instrument on earth for the further ance of the great moral and religious interests of man." Hence, it has been taken as a model for forming other associations,—political, civil, or religious. Among the early Hebrews, and in eastern countries, the patriarchal form of government is only an extension of the family relationship. The Greeks regarded the family as a type of the state; and among the Romans the natural power of a father was taken as the basis of the whole social and political organization of the people.

The family life is based upon the wants and necessities of our nature, and is essentially fitted to develop and foster those habits and affections on which the happiness and welfare of mankind depend. It can only, ness and weizer of making depend. It can only, however, exist in a state of purity where monogamy prevails. In the family relationship we find clear evidence that the pretended state of nature, which has been represented as the primitive condition of man, is totally opposed to the benevolent designs of the Author of nature

FAMILY, in Bot., a synonym for Order (which see).
FAM, fin (Sax. funn), an instrument which is used
by ladies to agitate the sir, in order to create a sensation of coolness around them. It is manufactured of tion of coolness around them. It is manufactured of feathers, of paper, thin skin, or viory, joined together, and is generally carved and painted, in order to insure its embellishment. The fan is mentioned in the Grecian classics (Euripides); indeed, it was known in an era far prior, as there are paintings in the relies of Thebes to prove that the Egyptians were familiar with its use. The fan was first brought into European notoriety by Catherine de Medicis, who introduced it into France, where it was so constructed that it could be used and folded in a manner similar to the fan in use at the present day. Great sifins were spent on the

## Fandango

ornamentation of the fans first in vogue, and many were painted on by the cunning fingers of Watteau.
The Chinese have greatly excelled in the art of fanmaking, and in the species of lacquered fans their su-periority is fully admitted. The Chinese themselves use a cheaper sort, made of bamboo and paper, polished, which cost about tenpence each. In Europe, France manufactures the greatest number of fans used by the world of fashion. Of late years, the value of those manufactured exceeded £110,000 per annum. In the late Exhibition (1862), many pleasing specimens were shown to exhibit the high art to which fan-manufacture had arrived. A species of large fan is used in India for cooling the air of rooms and keeping down the temperature; for further information upon which, see article PUNKAH.

Fanatics, få-nåt'-iks (Lat. fanatici), is derived from the Latin fana, temples, and was applied to such as passed their time in temples, and, pretending to be in-spired by the Divinity, would burst into wild and antio gestures, utter pretended prophecies, cut themselves with knives, &c. Hence, the term has, in modern times, come to be applied to such as manifest a religious encome to be applied to such as manifest a religious en-thusiasm, uncontrolled by reason or experience, and proceeding from a belief that they are under divine direction, and doing what will be well-pleasing in the sight of God. Fanaticism is sometimes applied in a wider sense to any excessive prepossession of the mind by ideas of any kind. Fanaticism has prevailed under different forms in all ages of the world; and one of its most remarkable and dangerous features is the ten-dency that it has to appead over layer measure. dency that it has to spread over large masses of a people. It is not usually confined to one individual; for there are generally to be found others who are ready to take up and act upon the delusion. The very earnestness of the fanatic—and fanatics generally are in earnest—serves to carry conviction to the minds of others. Among persons of this class were Emanuel Swedenborg, Madame Guyon, Johanna Southcote, and numerous others. When confined to an adherence to certain theological dogmas, it is in a comparatively mild and harmless form; but sometimes it manifests itself in atrocities of the most cruel and heartrending description,—murders, assassinations, and the like. If ignorance be the mother of devotion, much more is it the mother of fanaticism; and the only fit cure for delusions of this sort is the spread of education, enabling people to judge rightly as to the relative importance of things, and to distinguish between the true and the false.

FANCY, fan'-se (Gr. phantasia), a corruption of phan-FARCY, fün'se (Gr. plantasia), a corruption of phantasy, was used by the ancient philosophers as coextensive with conception,—that power or faculty of the mind by which man reproduces the images of objects, apart from any impression on the organs of sense. It is now properly applied to a particular province of the imagination, though sometimes it is loosely used as synonymous with it. The office of the fancy, according to Mr. D. Stewart, "is to collect materials for the imagination." A man whose habits of association present to him for illustrating over habits of association present to him, for illustrating or habits of association present to him, for illustrating or embellishing a subject, a number of resembling or analogous ideas, we call a man of fancy; but for an effort of imagination various other powers are necessary, particularly the powers of taste and judgment."
"It is the power of fancy which supplies the poet with metaphorical language, and with all the analogies which are the foundation of his allusions; but its the nower of imaginations there are the source of imaginations. it is the power of imagination that creates the complex scenes he describes, and the fictitious characters he delineates. To fancy we apply the epithets of rich he delineates. To fancy we apply the epithets of rich or luxuriant: to imagination, those of beautiful or anblime Others, however, regard fancy as a higher aublime." Others, however, regard fancy as a higher evergy of the mental activity than imagination, and that it is "the imagination that furnishes the materials out of which it creates its phantasies, either by

modifying or exaggerating them, or by forming new combinations."—English Cyclopædia.

Fandargo, fin-ding-go (Sp.), is the name of an old popular Spanish dance, which proceeds gradually from a slow and uniform to the most lively, but neverrions slow and uniform to the most neily, out never-violent motion. It is denoted by two persons only, and represents the various gradutions of the passion of love to an extent bordering on the licentious. Ya-rious attempts have been made by the clergy to suppress this dance, but without success, though it is now shiefly confined to the theatres and parties of the

lower classes.
FARTASIA; făn-fai'-she-ă (Ital.), in Mus., a term used to denote an extempore performance, in which the musician gives full scope to his imagination; and which, although subjected to the fundamental laws of melody, modulation, and harmony, is not elaborated by any strict rules or forms of construction. This term also signifies a written composition, in which the com-poser indulges his fancy unrestrained by any conven-

tional forms or rules.

FANTOCCINI. (See PUPPETS.)
FARCE, farse (Fr. farce, Ital. farsa, Lat. farsum, staffed,—denoting a mixture of different things), is a dramatic piece of a low comic character, usually played as an after-piece. Its sole end being to excite mirth, it excludes nothing, however wild or extravagant, which may contribute to that object. It differs from comedy in this, that while the latter is based upon nature and truth, the former does not scruple to have recourse to any extravagance or absurdity that may serve its purpose. Farces are said to have been first introduced by the Society of Cleros de Bazoche, in Among the most celebrated of the Paris, about 1400. Among the most celebrated of the carly furces is that of "Maitre Pierre Pathelin," believed to be by Peter Blanchet, who flourished about 1460. Subsequently Molière greatly improved and elevated this class of dramatic literature. Farces usually partake of the character of the people to whom they belong; and hence the French, German, Italian, and Spanish farces have different characteristics.

FARINA (See FLOUR.)

FARMA. (See FLOOK).

FARMA, farm (Sax. farma, fearm), a portion of land cultivated for the purpose of profit. There are various kinds of farms. Arable farms are those in which the principal part of the land is under the plough; grazing farms are those in which the object desired is the fattening of cattle or other live-stock; dairy farms are those on which the chief intention is the production of milk, butter, cheese, &c.; lastly, those farms in which the arable and grass systems can be combined are called convertible farms. In some districts there are other subdivisions; such as hay or grass farms, and breeding or cattle farms. In all farms, the principal object at-tended to is the nature of the soil and its cultivation. (See ARABLE LAND, MANURE.) The farmery is usually situated near the homestead, or farmer's house; and the area or court in which the cattle are foddered, dung prepared, and other farming operations per-formed, is called the farmyard.

FARM ANIMALS .- These animals may be divided into two classes,-first, those which are used for draught or for cultivating the soil; and, secondly, those which are bred and reared upon a farm, either for dairy purposes or for the object of being soid at a profit. For draught and ploughing purposes, the horse is more employed in England than in any other country;—oven are much used among other nations. The best English plough horses come from Suffolk. The quicker action of the horse makes its work more productive than that of other animals. Amongst the farm animals which are bred for the purpose of sale, the most numerous are the sheep. The sheep is the easiest to feed of all animals, and derives the greatest benefit from what it main, and terves the greatest benefit from what it consumes; while it gives the most active and rich manure to the land. For this reason, the English farmer makes it his object to keep a large number of sheep. England has always possessed a great many sheep; the British isles were celebrated for this even in the time of the Romans. There are, at the present day, three principal breeds in England,—the Leicester, the Bouthdown, and the Cheviot. (See Sheep.) With regard to cattle, the principal objects of the English regard to catue, the principal objects of the English farmer in their rearing are the milk and meat. The milch-cow race, par excellence, of the British empire, came originally from the Channel Islands. The breed usually goes under the name of Alderney. The Ayrabirs can which first terms into retire short internal and the statement of the companies of the compan asiany goes under the battle of Attention, the Ayre say, as the Alderney cow's rival. Ireland possesses two races of milch cows. The first breed of cattle improved.

stand first: they first gained a reputation about 1775" Since that time, the race of improved short-horns has improved through the United Kingdom, and was some time ago introduced into France. The Hereford and time ago introduced into France. The Hereford and Devon breeds are reckoned next to the Durham in ex-cellence. The other farm animals of importance are cellence.

cellence. The other farm animals of importance are pigs and poultry. (See Pies, Poultry.)

Farmers-General, farm'-ers-jen'-s-ral (Fr. formiers généraux), was name given in France to the members of a privileged association, who, before the revolution of 1789, farmed certain branches of the public revenue, that is, paid the government a certain fixed annual sum for the right of collecting certain of the taxes. Under Francis I., in 1549, the duties on sult were first raised by furning the monopoly of its sale in each town. raised by farming the monopoly of its sale in each town. In 1599, Sully introduced the system of disposing of the right of farming the taxes to the highest bidder, and in this way greatly increased the public revenue. In 1728, under the regency, several of the individual leases. were united into a ferme genérale, which was let to a company, the members of which were termed fermiers généraux. In 1789, the number of fermiers general was denerates. In 1789, the number of termers general was forty-four, who paid annually into the treasury 180 millions of livres. They were possessed of extensive powers and privileges, conferred upon them by special decrees; and, from the manner in which they exercised their powers, they were riewed with great detestation by the people. Hence, during the Revolution, to which this in no small degree contributed, many of these odious taxgatherers perished on the scaffold, and an end was put to the system.

FARMING, furm'ing, the business or management of a farm, comprehending the whole circumstances and conduct of it. Farming was for a long period looked upon as a profession easily understood and successfully upon as a protession easily understood and successfully pursued only by an empiric. It is now, however, regarded in a different light, and of late years science has done great service to farming. The farmer, in order to follow his profession properly, not only requires perseverance and observation, but he should also have a sound knowledge of natural science. In England, the farmers may be arranged in the following classes:—

Large responsators and country gentlemen. 2. 1. Large proprietors and country gentlemen; 2. yeomen and farmers properly so called: 3. possessors of small farms; 4. cottagers, including different descriptions of persons who cultivate small farms and a few

acres adjoining to towns and villages.

FARO, fu'-ro, a game of cards, which used formerly to be much in vogue in England: at present, it is seldom if ever played. In the principles of the game, seldom if ever played. In the principles of the game, it is somewhat similar to range et noir. A croupler or banker, and a fulleur or dealer, sit opposite each other at an oval table, made expressly for the purpose, and covered with green cloth. Any number of persons may play, and, as a rule, the odds on the game are in favour of the croupler, who generally wins. The players have to bet on their cards winning against three dutters are the control of the croupler. those dealt for the bank, and can double their stakes every time they win. They are not allowed to increase their stakes, however, to more than sixteen times what they were originally.

FARRIERT, fire-er-e (Fr. ferrier, a horse-shoer, from Lat. ferrum, iron), in its most common acceptation, is the art of shoeing horses; but the term is also applied to the art of preventing, curing, or alleviating the disorders to which horses and cattle are subject. Before the commencement of the present century, the practice of farriery was entirely confined to a class of men who were mere horse-shoers, and who were not only utterly ignorant of the physiology and anatomy of the horse, but were also totally unacquainted with the principles of the art of healing. Since that time a veterinary college has been established, and a better class of persons have taken up the profession.

FARHINGALE, or FARDINGALE, far thing-guile, a petticoat expanded by houps of whalebone, &c. They were first introduced into England during the reign of Blizabeth; and after coming into and going out of fashion several times, they respected about 1856, in a more capacious form than ever, under the name of

crinolines (which see).

races of milch cows. The first breed of cattle improved in the midland districts was the long-horned. It is antiquity to a symbol of authority, introduced by the now pretty generally abandoned. Among the improved kings. The faces consisted of a bundle of rode breeds of long standing, the short-horns of Durham (usually birob) bound together, with an axe in the

#### Trancia

centre, the head of which projected so as to be visible to all. A class of officers somewhat similar to our old brefacters bore the fasses before the kings, and they were called lictors. The king was usually preceded by twelve lictors whenever he went abroad, and after the days of the kings, the consuls were allowed a similar number. The dictator was preceded by twenty-four lictors, to signify his unrestricted supremacy. Afterwards the lictors, with their fasces, were allowed, in diminished proportion, to each of the chief magistrates in the city, and even in the provinces.

FASCINES, file-seens' (Lat. fasces, bundles of rods with an axe bound up in the middle of them, carried by the lictors before the Roman consul or dictator), the name given in Mil. to long faggots, or bundles of A class of officers somewhat similar to our old

the name given in Mil. to long faggots, or bundles of the name given in Mil. to long laggoes or binders of brushwood, used for various purposes; such as forming the revetments of parapets in field-works, and making the roof of a blindage or magazine, which may be rendered bomb-proof by covering the fascines with a sufficient depth of earth. They are also used for making the proof of the proof o sufficient depth of earth. They are also used for making roads over wet, boggy ground. The fascine is made of twigs and sticks laid together longitudinally, and tightly bound with twisted willow or bazel rods at in-tervals of fifteen or eighteen inches. They are usually made eighteen or twenty feet in length, and shout nine inches in diameter. When they are used for the rewetment of a parapet wall, they are secured by driving long stakes through them into the bank of earth against which they are placed. Fascines are also used in civil engineering for making dams, protecting the sides of dykes, and in forming foundations for any superstructure, as well as hearting for banks and a bottom for newly-made roads. They are shorter and much thicker news-made roads. They are shorter and much thicker than the military fascine, seldom exceeding ten feet in length, but often being as much as four feet in diameter. They are placed side by side over the spot it is desired to cover, and then they are pinned to the soil beneath with long stakes, the tops of which are connected by means of rods interlaced between them. When this has been done, earth and stones are thrown on the top of the facines. Sometimes areas of considerable extent are covered in this manner; and when the surface on which they are to rest is under water, the facines are connected and floated over the spot, and then sunk into the desired position by stones and gravel placed on them; after which the necessary works may be constructed.

FAST, first (Ang.-Sax. fastan), denotes a partial or total abstinence from food, a due supply of which is necessary to maintain the body in a healthy and vigorous condition. The length of time during which a person may subsist without food is very various, even though we give no credence to those remarkable instances, some of which seem to be well-authenticated, that are given of life being maintained in the circumstances for a number of weeks. a number of weeks. (See HUNGER.) The term fast, a number of weeks. (See HUNGER.) The term fast, however, is more particularly applied to a religious observance,—the abstinence from food for a time, in order to "afflict the soul" and to increase a devotional feeling in the mind. Religious fasting may be said to have been practised in all ages and countries where any devotional feeling prevailed,—among the ancient Egyptians and Assyrians, as well as among the Hindoos and Mohammedans of the present day. In the law of Moses, we do not find much reference to fasting; and some are disposed to think that it was "among those some are disposed to think that it was "among those things which Moses allowed rather than originated, bore with rather than approved," as being an old and well-established practice. Of this, however, there does not seem to be sufficient evidence; and even though there were, we should not regard it as an arrival that the sufficient evidence. gument against fasting, as seems to be done by the writer in Kitto's "Biblical Cyclopædia," but that it arose from a fear that what ought to elevate and refine the inward feelings might degenerate into an empty out-ward ceremony. There is but one fast enjoined by the ward ceremony. There is but one fast enjoined by the great Hebrew lawgiver. On the tenth day of the seventh month, the great day of annual atouement, they were to "afflict their souls,"—a phrase which, doubtless, points to abstinence from food, as, indeed, is shown by the later practices among the Jews. Other general fasts were in course of time introduced, as commemorative of great national calamities. The prophet Zechariah enumerates four of these

## Fasti

being observed in his day: "the fast of the fourth month, and the fast of the fifth, and the fast of the seventh, and the fast of the tenth."—(Zech. viii. 19.) On particular and signal occasions, also, particular fasts were appointed, and private fasts were also common, especially among the later Jews. The abstinence usually lasted for twenty-seven or twenty-eight hours, becoming before any extended and additionally lasted for twenty-seven or twenty-eight hours, beginning before winset and not ending till some time after susset the following day. On these occa-sions they put on sackoloth and sprinkled ashes upon their heads, in token of their grief and repentance. Partial fasts were also occasionally observed on par-ticular occasions by action of them. ticular occasions by certain of them; as when Daniel tells us that he mourned for full three weeks, and "ate no pleasant bread, neither came flesh nor wine in my mouth, neither did I anoint myself at all till three whole weeks were fulfilled."—(Dan. x. 3.) Though fasting is not positively enjoined by Christ or his apostles, we have evidence in the New Testament that it was practised by the latter; and St. Paul, in enumerating what he had done and endured in the cause of Christ or the contract of the c enumerating what he had done and endured in the cause of Christ, says, "in watchings often, in hunger and thirst, in fastings often."—(2 Cor. xi. 27.) In the earliest times we do not find mention of any public and solemn fasts being observed except upon the anniversary of Christ's crucifixion. However, in process of time, days of fasting were gradually introduced, first by custom and afterwards by positive appointment. Towards the close of the 3rd century fasting cume to headd in when greater esteem from a noting came to be held in much greater esteem, from a notion that it served as a security against the machinations of evil spirits, who were believed to direct their efforts principally against the luxurious. Fasting came also be regarded as the most effectual means of appeasing the anger of an offended Deity; and hence it came to be looked upon as an indispensable duty, and express haws were enacted regarding it by the rulers of the Church. As it became more general, the severity of it was relaxed, and a mere abstinence from flesh and wine was judged sufficient. (See LEET.) The strict canonical fast only allows one meal in twentyfour hours. By the regulations of the Anglican church, fasting, though not defined as to its degree, is inculcated at seasons of peculiar penitence and humiliation as a valuable auxiliary to the cultivation of habits of devotion and of self-denial. The writer in Kitto's Cyclopedia already referred to draws from the words "Can the children of the bridechamber fast when the bridecroom is with them?" (Matt. iz. 14) the conclusion that it "involves an entire disapproval of fasting in the Christian church;" but we believe that the transfer of the t that most persons will be rather inclined to adopt the opinion of Dr. Hook, that the time when he, the brideopinion of Dr. Hook, that the time when he, the bride-groom, was with them would be an improper season for tokens of sorrow; and that he at the same time intimates that it would be their duty thereafter; a view which is confirmed by its being practiced by the apostles after his ascension. On the general subject of fasting he says, "All must acknowledge that this reetraint, even upon the innocent appetites of the body, is eminently beneficial in assisting the operations of the mind. It brings the animal part of our nature into greater sub-servience to the spiritual. It tends to prevent that brings the animal part of our nature into greater subservience to the spiritual. It tends to prevent that heaviness and indolence of the faculties, as well as that perturbation of the passions, which often proceed from indulgence and repletion of the body. It is thus highly useful in promoting that calmness of mind and clearness of thought which are so very favourable to meditation and devotion. The great end of the observance is to afflict the soul, and to increase a genuine contrition of heart and godly sorrow for sin." In the practice of fasting, then, the intelligent Christian will not rest in the outward act, but regard it only as a means to a good end,"—(Hook's Church Dictionary.) The distinction between the Protestant and the Homish view of facting is this, that the Roman regards the use of fasting as a means of grace, man regards the use of fasting as a means of grace, the Protestant only as a useful preparation for the

means of graces.

East, far'te, used in Roman antiquity for the purpose of signifying kalendars, in which were comprised their feasts, fast-days, and days set spart for the celebration of games and other ceremonies. There were two different kinds of fasti,—the fusti kalendares and

823

the fasti magistrales,—the less and the greater. The former were merely as kind of diary, in which all the days were recorded as feasts, fast-days, &c.; the latter was more of a record of things appertaining to the gods, the emperors, and the magistrates. The fasti were also registers of different periods when the different years were denominated, of the names of the various consuls, and the principal events and circumstances which occurred during their consulate were thus recorded. This register was termed fasti onsulares, or the consular register. The dies fasti were always marked in the kalendar by the letter F. The classic poet Ovid celebrates the fasti in his Libri Fastorum.

FATALISM is a belief in fate, an unchangeable destuny, to which everything is subject, uninfluenced by reason, and pre-established either by chance or by the Creator. A fatalist is one who believes in fatalism.

TATA MORGANA, ful-ta mor-ga'-na (Ital.), a singular phenomenon of unusual refraction, seen in the Straits of Messina. It is sometimes called "the castles of the fairy Morgana." When the rising sun shines so that the incident rays of light form an angle of 45° on the Sas of Reggro, and the bright surface of the water is not disturbed, and the tide is at its height, certain phenomena have been observed by several travellers, to which the name of Fatz Morgana has been given. Minass states that when an observer is placed with his back to the sun, and his face to the sea, the mountains of Messuna, rising like a wall behind it, and forming the background to the picture, suddenly there appear in the water various objects,—countless series of columns, arches, castles, well-delineated pillars, loft towers, magnificent palaces, with balconies and windows, herds and flocks, armies of men on foot and on horseback, and many other things in their natural solours and proper actions during the whole of the short period of time while the above-mentioned causes remain. As the day advances, the magic scene vanishes sway. There is no doubt that this account of Minasi's is exaggerated, and had received considerable additions from his imagination; but, from many other accounts, it appears certain that the mirage at this place produces some very remarkable effects. Capt. Smyth, in his work upon Sicily, observes:—"I never met with a Sicilian who had actually seen snything more than the loom, or 'mirage,' consequent on a paculiar state of the atmosphere; but which, I must say, I have here observed many times to be unusually strong." Similar appearances occur, also, in the great sandy plains of Persia, of Asistic Tartary, of Lower Egypt, on the Masins of Mexico, in North America, &c. (See Misage.)

observed many times to be unusually strong." Simil's appearances occur, also, in the great sandy plains of Persia, of Asistic Tartary, of Lower Egypt, on the plains of Mexico, in North America, &c. (See Miragr.)

Fare, fait (Lat. falum), denotes, in a general sense, an inevitable necessity dependent on some superior cause. It is derived from fundum, 'speaking,' and primarily implied a word or decree spoken by a deity, the order of things divinely prescribed, according to which there is allotted to every person what shall befall him. It was also sometimes employed to denote the connection of causes in nature, or in the divine appointment, forming, as it were the links of a chain, in which all things are indissolubly united together. It as as used to express a certain unavoidable designation of things, by which all agents, both necessary and voluntary, are awayed and directed to their ends. Fate is sometimes divided into physical and divine; the former being the order and series of natural causes appropriated to their effects, the latter what is more usually called providence. According to Leibnitz, there are three kinds of fate,—" s fatum Mohometz, there are three kinds of fate,—" s fatum Mohometz, there are three kinds of fate,—" s fatum Mohometz, there are three kinds of fate, and mohomet should be avoided, as if there was an absolute mecessity. The Stoical fate will have a man to be quiet, because he must have patience whether he will or not, since 'tis impossible to resist the course of things. But 'the sure are and the foreknowledge and providence of God."

and providence of God.

FATHERS, THE, fat-therz (Sax. fxder), a name applied to the early writers of the Christian church,—those writers who have given us accounts of the trathose writers who have given us accounts of the trathose writers who have given us accounts of the trathose writers who have given us account of the trathose who have during the first six centuries of the Christian era, 1824.

and no writer is dignified with the title of father who wrote later than the 12th century. They are frequently divided into the Greek and Latin fathers; and those who flourished before the council of Nice, in 325, are called the ante-Nicene fathers. The chief fathers of the first six centuries were as follows:—In the let centhe first six centuries were as follows:—In the 1st century flourished Clement, bishop of Rome, and Ignatius, bishop of Antioch; in the 2nd century we have Polycarp, bishop of Smyrns, Justin Martyr, Hermias, Diouysius of Corinth, Hegesippus, Tatian, Athenagoras, Theophilus, bishop of Autioch, Ireneus, bishop of Lyons, Clement of Alexandria, and Tertullian; in the 3rd century, Minucius Felix, Hippolytus, Origen, Cyprian, Dionysius, bishop of Alexandria, Gregory (Thaumsturgus); in the 4th century, Arnobius, Lactantius, Eusebius, Julius Firmicus Maternus, Hilary, bishop of Poitiers, Athanasius, Basil. Enbrain the tantius, Eusebius, Julius Firmicus Maternus, Hilary, bishop of Potiters, Athanasius, Basil, Ephraim the Syriam, Cyril of Jerusalem, Gregory of Nazianzen, Gregory of Nazianzen, Gregory of Nazianzen, Gregory of Nazianzen, Gregory of Milan, Epiphanus, bishop of Salamis, Chrysostom, bishop of Constantinople, Ruffin, presbyter of Aquileia; in the 5th century, Jerome, Theodorus, bishop of Mopeustia, Augustine, Cyril of Alexandria, Vincent ef Lerins, Isidore of Pelusium, Theodoret, bishop of Cyrus in Syris, Leo I., surnamed the Great, Vigilius, bishop of Thapsus; in the 6th century, Procopius of Gaza, Aretas, Gregory, bishop of Tours, Gregory I., surnamed the Great, bishop of Rome. The last of the fathers is Bernard of Clairvaux, who died about the middle of the 12th century. Ecarned men and theologians differ very much in opinion as to the value that is to be attached to the writings of the fathers. that is to be attached to the writings of the fathers. By some they are looked upon as nearly of equal auby some they are looked upon as hearly of equal tu-thority with the Sacred Scriptures themselves, and as the most excellent guides in the paths of piety and virtue. Others regard them as unworthy of the least attention, considering them the very worst of all instructors, and treating their precepts and decisions as perfectly insipid, and in many respects pernicious. The right we believe lies between these two extremes; The right we believe lies between these two extremes; and while the Roman Catholics exalt too highly the opinions of the fathers, yet by Protestants generally they are too much disregarded. Their writings contain many sublime sentiments, judicious thoughts, and things naturally adapted to form a religious temper and to excite pious and virtuous affectious; at the same time, it must be confessed that, on the other hand, they abound still more with precepts of an excessive and unreasonable austority, with Stoical and Academical dictates, with vague and indeterminate notions, and, what is still worse, with decisions absolutely false and in manifest opposition to the character and commands of Christ. Of the character and doctrines of the priwithin a comparatively short period of the apostles, there are many things which they relate regarding apostolic times which had come down to them by tradition, and which are therefore not to be altogether dition, and which are increment and the rejected. In many cases, therefore, they are to be deemed as competent witnesses of facts; but we must not confide in their decisions as judges. They had to not confide in their decisions as judges. They had to contend with numerous adversaries, and in the heat of controversy they not only fell into various misukes, but made use of very unsatisfactory methods of reasoning, betraying imbecility of judgment or inattention to the principles and rules of logic. Their works, instead of being distinguished by correctness and strength of argument, furnish innumerable examples of feeble reasoning, of interpretations of Scripture irreconcil-able with good sense, and of a careless admission of

spurious writings as genuine authority.

FATROM, fath om (Sax, fathom), a measure of length containing six feet. It is principally employed in ascertaining the depth of water and mines, and for

regulating the length of cordage and cables.

Fars, fits (Sax. fet, fat).—In Chem., these important compounds are so nearly connected with the fixed oils, that it will be necessary to consider the properties of both under one head. The fats and fixed oils form a well-deflaed natural group of organic compounds, occurring abundantly both in the animal and vegetable kingdoms. Although, in common language, we speak of coal oils and essential oils, neither of these must be confounded, chemically, with the true fixed oils. The vegetable fats and oils are found.

Fear

in various parts of the plant, but they are most shundant in the seeds. The seeds of the Crucifore anuncant in the seeds. The seeds of the Cracifere especially yield a large quantity of eil; rapeseed, for instance, containing from 30 to 40 per cent. In animals, fat is found distributed through most parts of the body in warm-blooded animals, while in fish, and cold-blooded animals generally, its place is taken by oils. Fats and oils are extracted from animal and by oils. Fate and oils are extracted from summa and vegetable matter by simple pressure, or else by boiling. They are all lighter than water, their specific gravity varying from 0.31 to 0.94. They are all soluble in ether, benzole, and turpentine, and may be mixed with each other in any proportion. They are insoluble in the control of in water, and only to a certain extent in alcohol. They may be heated to 500° without undergoing any change; but on distilling them, they break up into various compounds, giving off acrid and offensive smells. Hence the term of fixed oils. They consist of a mixture of at least three proximate principles in different proportions, two of which, steurin and pulmitin, are solid at ordinary temperatures, and the third, olein, which is liquid. The proportions in which olein is present constitute the real difference between a fat and an oil. When hydrated alkulies are added to fats or oils, a process takes place, which is termed saponification, or the formation of soap. The theory of this process will be found under SOAP. (See also FATTY ACIDS.) The principal oils used in daily life are olice oil, the uses of which are well known; almond oil, extracted from the kernel of the common almond; colza oil, largely used for illuminating purposes, and which is obtained from the Brassica oleifera; linseed oil, sperm, whale, cod-liver oil. The solid fate are cocoanut oil, which is nearly solid at ordinary temperatures in this climate; palm oil, butter, lard, tallow, and suct. The subjoined list of animal fats and their melting The subjoined list of animal fats and their melting points has been given by the late Dr. Robert D. Thomson:—Badger fat, 86°; beef tallow, 984°; calf tallow, 136.8°; camel, 131°; cochineal fat, 104°; cow's butter, 79.7°; duck's fat, 77°; dog, 793°; fox, 129°; hare, 1174°; hog's lard, 80.5°; horse grease, 140°; human fat, 77°; pheasant, 109°; turkey, 113°; stearin (human), 120°; stearin (sheep), 109°; stearin (oxen), 111°; stearin (bog), 109°; stearin (duck), 109°; cetin, 120°; cantharides fat, 934°; palmitin, 115°.

Fatty Actos, füt'te.—In Chem., when a fat or oil is saponified by an alkali, a peculiar change takes place, the stearin, palmitin, and ofen, of which it is composed, and which are the stearute, pulmitate, and

place, the stearin, paimitin, and oten, of which it is composed, and which are the stearute, pulmitate, and oleate of glyceryl, respectively leave the glyceryl and unite with the alkali to form stearute, pulmitate, and oleate of potash or soda, as the case may be. On decomposing either of these compounds with a strong mineral acid, the alkali unites with it, setting the fatty mineral acid, the sixtail unites with t, setting the sativy soid free. This may be easily tried by dissolving some tallow or oil in a solution of potash or soda, and pre-oppitating the fatty acids by means of oil of vitriol. The fatty acids fall into two groups,—the stearic series and the oleic series. The principal members of the former are the mellisic and cerotic, found in bees-; the stearie, found in most animal fats; the sitic, found in palm oil; the laurie, found in cocoanut oil; and the butyric, found in butter. The principal members of the oleic series are the crucic, found in mustard-seed and rapeseed; the olsic, found in all non-drying oils; the physetoleic, found in sperm oil; and one or two others of common import. Oils are commercially divided into drying and non-drying oils, the former absorbing oxygen from the air and forming

the former absorbing oxygen from the air and forming a solid, the latter remaining liquid.

FATUTIVE, fat.w-o-te (Lat. fatuitas, from fatuus, foolish), denotes foolishness or weakness of mind. The fatuous are distinguished from the imbecile, or idiots, in that the mental powers which they once possessed have been impaired or extinguished, whereas, in the case of the latter, the mental powers have been deficient from birth. There are various degrees and kinds of fatuity. It may amount only to some incoherence of ideas and words, or the patient may be deprived of all consciousness; it may merely enfeeble the intelligence or memory, or it may pervert the moral nature. (See INSARIEX.)

moral nature. (See INSANIET.) furnithments, in Anat, is the gorne, or back part of the mouth, terminated by the gullet. 825

FAULTS, faults (Fr. faute, defect), in Min., a miner's term for any fissure accompanied by a displace-ment of the strata. Slip, slide, heave, pitch, and throw are also common miner's terms for the same thing.

are also common miner's terms for the same thing.

FAUN, faun, a name given, in Roman Myth., to a class of deities supposed to inhabit the groves and forests. The fauns are nearly identical with the panes of the Greek mythology. These rural deities are supposed to be the descendants of Faunus, one of the kings of Latium, who was worshipped as presiding over fields and herds; and he is thus identified with the Greek Pan and the Bgyptian deity Meudes. The ceremony of the Faunalia was one of those celebrated by the country people of Rome, and it took place on the 5th of December.

FAUNA, fuw-na, a term employed by naturalists to express the whole of the members of the suimal kingexpress the whole of the memoers of the animal sing-dom living in a particular district, or at a particular time. Thus all the animals living in Great Britain constitute the British fauna. Those inhabiting the land form the terrestrial fauna, and those inhabiting the seas, the marine fauna. It is often applied, oul-lastivaly to all the animals of the world, the extinct the seas, the marine launa. It is often applied, or-lectively, to all the animals of the world, the extinct species constituting the fossil fauna, and the living species the recent fauna. The word is derived from the Fauni, who were supposed to be the patrons of wild animals.

FAUSSE-BRAYE, fose'-brai (Fr. fausse-braye; Ital. fossa-braa), in Mil., the name given to a low rampart and parapet, which was sometimes raised in the ditch surrounding the enceinte of defensive works of the 15th, 16th, and 17th centuries, round the base of the main rampart of the fortress, and extending about 20 feet beyond it. The terre-plein, or surface of the ground within the work, was generally on a level with that of the surrounding country, and therefore below the creat of the glacis. A parapet wall was thrown up round the outer edge of the mound, which was sometimes pierced with embrasures for caunon. The fausse-braye seems to have been an addition to the main rampart that was more beneficial to the attack. main rampart that was more beneficial to the attacking party than to the defenders, as no effectual free could be directed from thence until the enemy appeared on the crest of the glacis, and it would afford considerable assistance to an attacking force in scaling the walls of a fortress, after effecting a lodgement in the distribution. It appears to have had its origin in a bank the ditch. It appears to have had its origin in a bank of earth that was frequently thrown up against the walls of ancient cities, to protect them in some measure from the assault of the battering-rams, and to have been superseded by the introduction of the

covered way.

Fawn, an appellation given to a buck or doe of the

FAWN, an appellation given to a Duck of doe or the first year. (See Darn.)
FRAIN, fe-dl'-te (Fr. feaulté; Lat. fidelitas), in Law, denoted, under the leudal system, an obligation on the part of the vassal to be faithful to his lord, and to defend him against all his enemics; and by the fendal law, an oath of fealty was required to be taken by all tenauts to their landlords, which was couched in almost the same terms as our ancient oath of allegiance, which a subject owed to his sovereign. Foreign jurists generally regard fealty and homage as convertible terms, because in some countries they are jurists generally regard fealty and homage as convertible terms, because in some countries they are blended, so as to form one engagement. In this country, however, they are distinct, homage being the acknowledgement of tenure,—the oath taken by a tenant when he comes to his land; and fealty, the oath of fidelity by a vassal to his lord. The oath of homage is taken by the tenant kneeling, that of fealty standing, and includes the following obligations:—(1) incolume, that he do no bodily harm to his lord; (2) incolume, that he do no bodily harm to his lord; (2) tutum, that he do no secret injury to him in his house : (3) honestum, that he demage not his reputation; (4) still, the he do no damage to him in his possessions; (5) fucile, and (6) possibile, that he make it easy and possible for the lord to do any good which was before in his power to do.

in his power to do.

Fran, feer (Sax. feron), in Ethics, is a painful emotion, or unessiness of mind, excited by the apprehension of impending evil, and accompanied with a desire of avoiding it. It shows itself by paleness of the cheek, sinking of the spirits, trembling of the limbs, hurry and confusion of mind, sometimes producing lainting, and even death. Sometimes it rouses

Federal Government

nature to exert itself to the utmost to avoid the approaching evil, and often things almost incredible have been performed under its influence. The fear of God is such an awe and reverence for the Supreme God is such an awe and reverence for the Supreme Being as renders a man religiously careful not to offend him, but to endeavour to please him in all his actions, and to cultivate such a temper and dispo-sition of soul as are agreeable to the Divine nature. It evidences itself by a dread of his displeasure; a desire of his favour; regard for his excellences; submission to his will; gratitude for his benefits; sin-cerity in his worship; and conscientious obedience to cerity in his worship; and conscientious obedience to his commands. Fear was deified by the ancient Greeks and Romans.

FRAST, or FESTIVAL, feest (Lat. festum), in a religious sense, is a ceremony appointed to commemorate a certain event. Some derive the word from the Latin feriari, to keep holiday; others from the Greek hestiao, I feast or entertain, from hestia, a hearth or fire. Almost every religion, true or false, has had its solemn feast-days. The ancient Greeks and Romans had them, as well as the Jews and modern Christians, God appointed several festivals among the ancient Jews, the first and most ancient of which was the Sabbath, or seventh day of the week, commemorative of the creation. The Passover was instituted in memory of their deliverance out of Egypt, and of the favour of God in sparing their first-born, when those of the Egyptians were slain. The feast of Pentecost was celebrated on the 50th day after the Passover, in memory of the law being given to Moses on Mount Sinai. The feast of tents, or Tabernacles, was insti-tuted in memory of their fathers having dwelt in tents tated in memory of their fathers having dwelt in tents for forty years in the wilderness, and all Israel were obliged to attend the temple and dwell eight days under tents. These were their principal feasts; but they had numerous others; as the feast of Trumpets, the feast of Expistion or Atonement, the feast of the Dedication of the Temples, the New Moons, &c. In the Christian church, no featural appears clearly to have been instituted by Jesus Christ or his apostles, wet Christians have always eslebrated the memory of yet Christians have always celebrated the memory of his resurrection, and numerous others were introduced at an early period. At first, they were only appointed to commemorate the more prominent events in the life and commemorate the more prominent events in the life and death of our Redeemer, and the labours and virtues of the apostles and evangelists; but martyrs came soon after to be introduced, and by the 4th century their number had increased to a very extravagant extent. And not only so, but instead of being spent in devotional exercises, they were employed in the indulgence of sinful passions, and in criminal pursuits; indeed many of the festivals ware invitived on. indeed, many of the festivals were instituted on a pagan model, and perverted to similar purposes. Fessets are either movable or immovable. Immovshe feasts are such as are celebrated constantly on the same day of the year, the principal of which being Christmas-day, Circumcision, Epiphany, Candlemas or Purification, Lady-day or the Annunciation, All Saints', All Souls'; besides the days of the several apostles as St. Thomas, St. Paul. Movable feasts are such as as St. Thomas, St. Paul. Movable feasts are such as are not confined to the same day of the year. Of these, the principal is Easter, which gives law to all the rest, all of them following and keeping their proper distances from it; as Palm Sunday, Good Friday, Ash-Wednesday, Sexagesima, Asception-day, Pentecost, and Trinky Sunday. Besides these, which are general, there are others which are local or occasional, enjoined by the magistrate, or voluntarily set on foot by the people. "There is something truly admirable in the order and succession of these holy days. The Church begins her ecclesiastical year with the Sundays in Advent to remind us of the coming of Christ in the in Advent to remind us of the coming of Christ in the flesh. After these, we are brought to contemplate the mystery of the incarnation; and so, step by step, we follow the Church through all the events of our Sa-

follow the Church through all the events of our Saviour's pilgrimage to his ascension into beaven."

FERTHESS, felt-ers (Ang.-Sax.), the general name for the exterior covering of birds. They consist of the quilt, the shaft, and the vanes. The quill is a hollow semi-transparent horny cylinder, by which the feather is attached to the skin. It combines strength with lightness in a very extraordinary manner. The cavity of the quilt contains a series of copical espules united together by a central pedicle, forming the mem-

branous remains of the original formation-pulp. brancus remains of the original contacton-pulp. The shaff is quadrilateral, with a smooth convex surface: it contains a white, dry, and very light pith. The cases are subdivided into two parts,—the barbs and the barbules. The sides of the shaft are covered with the barbs, and each barb forms of itself a small shaft, which is covered in a similar manner with little barbs on each edge. Those barbules are so firmly bound to each other, that although, in reality separate, they seem to adhere. The feathers of birds are changed at periodical intervals. This is called "moulting." at periodical intervals. This is called "moulting," Festhers vary in their size, form, and function, and in most cases are accompanied by an accessory plume, which is usually in the form of a small downy tuft. In high northern latitudes, the inhabitants wear the skins of some birds with the feathers ou, as clothing. In Greenland, clothes made with the skins of eider-ducks are worn with the feathers inside. The ancient Mexicans made pictures with the coloured plumes of humming-birds, after the manner of mossic. Feathers make a considerable article of commerce. The feathers of the ostrich have been held in high estimation from the times of antiquity, and have been used tion from the times of antiquity, and have been used as ornaments for the fans and head-dresses of ladies, the helmets of warriors, and for gay processions.

Many parts of England and Scotland supply feathers for beds, and an inferior sort is imported from Ireland. The finest feathers used for this purpose are those of the eider-duck, which is obtained in Greenland, Ice-land, and Norway. Very fine feathers, especially for land, and Norway. Very fine feathers, especially for quills, are obtained from Hudson's Bay. Down, or the first covering of young birds, is also an article of commerce. The down of the swan is brought from Dantzic, together with a large quantity of superior feathers. In 1845, a duty, which had, up to that time, been levied on feathers, was ropealed. (See BINDS.)

FEBRUARY, feb-ru-a-re ((Lat. Februarius, from februo, I purify), is the name of the second month of our year, and contains ordinarily twenty-eight days, except in leap-year, when it has twenty-nine, an in-terculary day being added. It is so called because in that month funeral lustrations were performed at Rome. It was introduced into the calendar by Nums, who gave it the twelfth place; but the decemviri sub-sequently transferred it to where it now stands.

FECIALES, fe-she-ai-leer, priests among the Romans, Etruscans, and other sucient nations of Italy, who acted as heralds of peace and war. Their persons were sacred from injury when engaged on any mission to a hostile state, as the persons of ambassadors, and messengers under a flag of truce, are inviolate in the present time. Their duties in some few particulars resembled those of the heralds of the middle ages. If the people of any city or nation had committed an act of aggression against the Romans, one of the leciales was sent to state the wrong that had been perpetrated and to ask for reparation. After a few days had elapsed, the herald made a second visit to receive the answer which might be prepared to the demand made by the Roman authorities. If it was unfavourable, the herald Roman authorities. If it was unfavourable, the herald again returned to Rome and stated the results of his mission, and if war was determined on by the consuls and the senate, he proceeded a third time as far as the boundaries of the offending state, and hurled a bloody spear within them, which was considered to be equivalent to a proclamation of war, and an intimation that open hostilities had commenced. It was also the duty of these sacred heralds to complete treaties of peace with nations with which the Romans had been engaged in war, and treaties of alliance with those who were on terms of friendship with the powerful Roman people. The Roman feciales were twenty in number, and formed a kind of college of heralds, insti-tuted by Numa Pompilius, the second king of Rome, about 710 B.c.

FEDERAL GOVERNMENT, fed'-e-rul (from Lat. fedus, a league), is a government formed by the union of a seque), is a government formed by the union of several sovereign states, each state giving up a portion of its power to the central authority, and yet retaining its powers of self-government. It differs from a con-federacy in this, that each of the states that compose the latter is properly independent or supreme, the central authority having no power to enforce sny of its measures upon the individual state, that being in the hands of their own governments. The Germanie

## Federalists

confederation belongs to this class, the diet being merely an assembly of ambassadors from several confederated but independent governments, and the resolutions of the diet being merely articles of agreement which each of the confederated governments spontaneously adopts, but which owe their legal effect in each state to laws and commands fashioned upon them by its own immediate chief. The common form of a federal government is where the central authority is vested in the hands of representatives appointed by the sovereign power of each state. Their powers are determined by the contract, and vary in different cases. In some, as in the Swiss cantons, it is little more than a confederation; in others, as in the United States of America, it approaches to a union. "The federal congress of the American union," says Mr. Mill, "is a substantive part of the government of every individual state. Within the limits of its attributions it makes laws which are obeyed by every citizen individually, executes them through its own officers, and enforces them by its own found, or which is even likely to produce, an effective federal government."—(Representative Government.)
Federations of a kind existed in smalent times, as that of the Edician league, &c.

the Etolian league, &c. .

FEDERALISTS, fed-e-räl-ists, was the name of a political party in the United States formed in 1788, and who claimed to be the peculiar friends of the constitution and the federal government. Their most distinguished leaders were Washington, Adams, Hamilton, and Jay, and the leading federalist states were Massachusetts and Connectiont, supported generally, though not uniformly, by the rest of New England; while Jefferson, Madison, Munroe, Barr, and Gallatin, led the opposition. Their opponents, the republicans, they called anti-federalists, and charged them to a certain extent with hostility to, or distrust of, the United States constitution and the general government. In the contests of the French revolution the federalists leaned to the side of England, the republicans to that of France. The opposition of the federalists to the war of 1812, and above all the calling of the Hartford convention, effected their destruction as a national party, and in 1820 they were completely disbanded. During the flerce struggle between the Northern and Southern states, the Northern party, who were in favour of maintaining the Union, were designated as Federalists. The Southern states, who desired to form themselves into an independent confederation.

independent confeiteration, were termed Confederates. Fire, fee (Sax. feh or fech, Lat. feudum or feodum), in Law, is the same with feud or fief, and in its original sonse is used in opposition to allodium, the latter denoting land beld by a person in his own right, without owing any rent or service to any superior; whereas fee or feodum is applied to that which is held of some superior, on condition of rendering him service. As no subjects can be possessed of allodial property in England, all lands being held either mediately or immediately of the crown, a fee in general is the highest and most extensive interest that a man can have in a feud. Estates of inheritance are either estates in fee simple or fee tail. An estate in fee simple is the most extensive estate of inheritance hat a man can posses in land, and is descendible to his heirs. Estates in fee simple are commonly divided into three kinds:—1. Fee simple absolute; that is, free from any qualification or condition.—2. Fee simple qualified, or base, one which has a qualification sunered to it, and which determines whenever the qualification subjoined to it is at an end; as in the case of a grant to A and his heirs, tonants of the manor of Dale,—S. Fee simple conditional is a fee restrained in its form to some particular heirs, to the exclusion of others. (For an account of estates in fee sail, see Entate.)—Ref. Stephon's Commentaries.

manor of Dale.—3. Fee simple conditional is a fee restrained in its form to some particular heirs, to the exclusion of others. (For an account of estates in fee tail, see ENTAIL.)—Ref. Stephen's Commentaries.

FER, in the law of Scotland, denotes a full right of proprietorship in any property, and is distinguished from life-rent, which is merely the right to enjoy it during life. Frequently the two terms occur together, and an estate is said to be granted to a parent in life-rent and his children in fee.

# Feigned Diseases

FERLING, freal-ing (Sac. felan, to feel), is primarily employed to denote the perceptions which we have of external objects by the sense of touch; but it has also come to be applied to our inward sensations. Thus a man may have a feeling of pleasure from heat, or from contemplating a beautiful landscape. In this way we have intellectual feelings, moral feelings, sensual festings into two great classes,—the mental and the corporeal, or, in other words, into sentiments and sensations. Though, strictly speaking, all conaciousness and all feeling be only mental, yet there are certain feelings that are clearly marked out to be in proximate relation to the body, and these he terms sensual feelings or sensations, while the internal or mental feelings he terms sentiments. The sensations are divided into two classes,—those which accompany our perceptions through the five determinate senses of touch, taste, smell, hearing, and sight; and those which are comprised under the common or vital sense which are comprised under the common or vital sense which are comprised under the common or or divided into two classes,—contemplative and practical; the former being the concomitants of our cognitive powers, or powers of knowledge; the latter of our powers of conation, or of will and desire. (For a very elaborate analysis of the different feelings, see Sir William Hamilton's Metaphysical Lectures, vol. it has the concess of the powers which they attend."

ences of the powers which they attend."

FEES are certain sums of money paid to official persons as perquisites, or as recompense for their labour and trouble, and are fixed by sacient usage or by acts of parliament. The fees paid to officers connected with the administration of justice have been in most cases fixed and regulated by recent acts of parliament. Officers demanding improper fees are guilty of extortion (which see). The fees of barristers and physicians are regarded as konoraria, and cannot be

recovered by legal proceedings.

FRIGWED DISLASSS, fained (Fr. feindre, to feign), are disgases which certain persons pretend to be afflicted with, in order to avoid some duty, or in the hope of gain. The soldier, to escape the performance of duty; the mendicant, to impose on public or private beneficence; the criminal, to avoid the infliction of punishment, most frequently have recourse to these pretences. They are sometimes, however, had recourse to when no adequate motive can be assigned, and are difficult of detection in proportion to the skill with which they are simulated; and Fodère has observed that during the conscription in France the subject had been "brought to such perfection as to ronder it as difficult to detect a feigned disease as to cure a real one." The diseases most commonly feigned are epilepsy, catalepsy, convulsions, blindness, deafness, palsy, insanity, indigestion, neuralgia, rheumatism, palpitation of the heart, ulcers, &c. Vomiting, spitting of blood, diarrhea, and ophthalmia, are also often simulated. It frequently demands very considerable ingenuity on the part of the physician to detect the knavery of such persons. The physician, after ascertaining that the apparent disease is capable of being simulated, and how far it is so, should endeavour to learn what motives the patient may have for playing such a part. His intelligence should be gauged, and the accordance of the disease with his age, sex, condition, &c., carefully examined. He should also ascertain from the relatives or friends of the suspected person what are his physical and moral habits. "But the chief dependence," says M. Rostam, "must be placed upon well-directed questions, for the impostor is rarely so familiar with the symptoms of his assumed malady as not to betray himself when asked if he does not feel certain symptoms foreign to his case, or to contradict himself when questioned at different times regarding the course of his disease. His embarrasement is likely to be much increased when he is cate-ohised respecting

## Felo de Se

light is thrown upon these cases by an examination of the involuntary functions. In diseases in which the pulse ought to be affected (and there are few which do not affect it), its condition will often lead at once to a detection of the imposture." There is generally, also, an aversion in persons feigning disease to take the proper remedies.

FRINT. (See FRICING.)
FELIDE, or FELINA, fe'-le-de (Lat. felie, a cat), a fam. of the Cat kind, of the order Carsioora, in which the destructive organs reach the highest perfection. This fam. is by some naturalists said to include the dogs, hyenas, wolves, and smaller carnivors; but the system generally adopted is to include among the Felina only the cats, itons, tigers, leopards, and lynxes. In these animals the head is short and almost rounded in its form. The principal instruments of the destructive energy of these animals are the teeth and claws. Their dental formula is as follows :-

Incisors  $\frac{6}{6}$ ; canines  $\frac{1-1}{1-1}$ ;  $\frac{\text{pris-}}{\text{molars}} \frac{4-4}{2-2}$ ;  $\frac{2-2}{1-1}$ The canines are long, sharp, compressed, and cutting; the pramolars are furnished with two roots, compressed, pointed, and serrated; the flesh-teeth, or true molars, are very large, sharp-edged, and terminated by two or three points; and behind the flesh-tooth in the upper jaw there is a small tubercular tooth, which is wanting in the lower. In addition to this formidable apparatus of cutting-teeth, the tongue in these animals apparatus of cutting-teeth, the tongue in these animals is covered with small recurred prickles, by which they can detach from the bones of their prey every particle of flesh. The palate is soft, and that part of the tongue which corresponds with it is smooth; as it advances forward, it is covered with large soft papille directed backwards; then there are four large fessulate papille, anterior to which the simple conical papille continue increasing in size to near the tip of the tougue. These papille are armed with the strong cuticular spines before mentioned. The five toes of the anterior and four toes of the posterior extremities of the cats are armed with very posterior extremities of the cats are armed with very strong, hooked, sub-compressed, sharp claws, which are preserved from being blunted by a peculiar ar-rangement of the phalanges. For this purpose the claw-joint of each toe is drawn back by ligaments attached to the penultimate joint, until it assumes a attached to the penulumate joint, until it assumes a perpendicular position, when the claw which it supports is completely retracted within a sort of sheath, and is entirely concealed by the fur. When, however, the animal springs upon its prey, the tendous of the flexor muscles of the toes implanted into the opposite surface of the phalanx overcoming the elasticity of the retractile ligaments, push forward the claws, and they are ready to be buried in the flesh of a victim. The lower surface of the foot is furnished with thick ball-like pads of the epidermis, upon which the animal walks; and these are the cause of the peculiarly noiseless tread which is characteristic of all the members of this family. It will be seen; on reference to any members of the cat tribe, that the mode of walking adopted by these creatures is different from that of man, monkeys, or bats. The weight of the body rests only on the toes, and not on the entire foot. The manner of walking is termed "digitigrade," from the Latin words digitus, a termed digitigrate, from the Latin words Legitus, a finger, and gradus, a step. Cats hunt in the gloom, and consequently, while escaping observation, require every ray of light that can be made available. The pupil is a long vertical fissure; but this only obtains among the a long vertical issure; but this only obtains among the smaller genera; for in all the Felina that surpass the occlot in size, the pupil again assumes a round form. "On the top of the skull there runs a tolerably high bony creat, which reaches its greatest elevation at the very back of the head. This bone-ridge is intended for the threatenest of the roughly mander middle which which the statement of the roughly mander mander. the attachment of the powerful muscles which raise the head and enable the animal to perform its prodigious feats of strength. Pausing awhile, and directing our attention to the anterior of the skull, a curious internal ridge of bone is seen, which rises to some little height and separates the two great divisions of the brain from and separates use two great unvisions of the origin from each other. In the cat tribe, this ridge arises entirely from that part of the skull which is known by the name of the 'parietal bone;' but in other carnivorous animals the 'occipital bone' is the principal source of this structure. The use of the bony ridge is not quite

certain; but it seems likely that it may play an impor-tant part in guarding the brain from the severe shocks which must be occasioned by the movements of the animals when they lesp upon their prey. Reverting to the exterior form, and passing from the head to the neck, we find that the first two vertebræ partake of a similar enlargement to that which has already been observed on the back of the skull. The vertebra which is nearest to the head, and is called the 'alias,' is broad and strong and appends laterally, whilst which is nearest to the near, and is called the atins, is broad and strong, and spreads laterally; while the second, or 'axis,' is long, and is developed upwards into a very powerful crest. The ribs are beautifully formed, and placed rather widely apart, giving plenty of room for the heart and lungs to perform their duties effectually. The vertebræ that fill the space between effectually. The vertebræ that fill the space between the ribs and the hip-bones are very large, and so exquisitely jointed together that they unite a graceful flexisitely jointed together that they unless grave in measure bility of movement with great musualar power."—(Reo. J. G. Woods.) With regard to the digestive organs of the Felida, the salivary glands are small, as might be expected where it can hardly be said that mastication is exercised. In the case of the lion, the stomach is divided, by a slight contraction in its middle, into two portions. As in most of the family, its muscular coats are very strong. Blumenbach observes, that in most are very strong. Blumenbach observes, that in most carnivorous quadrupeds, particularly those of a rapacious nature, the stomach bears a considerable resemblance, on the whole, to that of the human subject. "In the carnivora, the stomach, which is of a cylindrical form, has no culs de sac; the cesophagus opens at its anterior extremity, and the intestine commences from the posterior; so that everything favours a quick passage of the food, which receives no mastication, and is retained a very short time in the stomach. The intestine has no witches in small in diameter, but thus intestine has no valves, is small in diameter, but muscular, and the whole canal, when compared with the body, is extremely short, being as 3 or 5 to 1. It is worth noticing, that in the domestic cat they are as 5 to 1; but in the wild cat they are only as 3 to 1."—(English Cyclopadia.) The Felidar are distributed in all parts of the world, with the exception of Australia, but principally in the warmer regions, where alone the larger species are met with.

FELLARS, fel'-luks (Arab., poor), is the name of a people in modern Egypt who live in villages and culti-They are the most ancient race in that vate the soil. country, and are generally believed to be descendants of the old Egyptians, their physiognomy resembling that which is found on the ancient sculptures. They are a patient and laborious population, but are heavily taxed, and subjected to great hardships. They form the great bulk of the population of that country. Fallowentr, fel'-lo-ship (Sax, felaw, fellow), in a college, is an endowment entitling the holder to a share in the narrange and constitution this paragraph.

its revenues, and constituting him a part of the corporation. Fellowships are either original, having been constituted by the founder of the college, or endowed by subsequent benefactors. Formerly, most of the fellowships were restricted to the inhabitants of certain dioceses, or districts, or persons; but most of these restrictions have been removed by the commissioners, under the University Act of 1854. Some fellowships under the University Act of 1854. Some fellowships may be held by laymen, but, in general, they can only be held by persons in holy orders, or who are ordained within a specified time. They differ greatly in value, many of them being under £100 per annum, while some of them reach £700 or £800. Being paid out of the college revenues, which are for the most part received in corn-rents, they vary from year to year with the price of that commodity. The senior fellowships are the most lucrative, but all confer upon their holders the privilege of occupying apartments in the bolders the privilege of occupying apartments in the college, and certain privileges as to commons or meals. Fellowships are, in general, tenable for life, unless the holder marries, or inherite estates which afford a larger revenue, or accepts one of the livings belonging to the

FELO DE SE, fe'-lo-de-se (Lat., a felon of himself), is one that deliberately puts an end to his own existence, or who commits any unlawful malicious act, the consequence of which is his own death. He must, however, be of the age of discretion, and of sound mind, otherwise it is no crime. The law of England wisely and religiously considers that no man his a right to take away his own life, and that the suicide is

## Felony

guilty of a double offence,—one spiritual, in evading the prerogative of the Almighty; the other temporal, against the king, who has an interest in the preservation of all his subjects. The law has, therefore, ranked this among the highest orimes, making it a peculiar species of felony, a felony against oneself. If one persuades another to kill himself, and he does so, the adviser is guilty of murder; and if two agree to commit saicide together, and one only is killed, the survivier will be willed of murder according to the to commit saicide together, and one only is killed, the survivor will be guilty of murder, according to law. Formerly, the body of the felon was ignominiously buried in the highway, with a stake driven through the body; but now, by 4 Geo. IV. c. 52, it is privately interred at night in a churchyard, and without the rites of Christian burial. All the chattels, real and personal, of a felo de se are forfeited to the crown, though they are usually restored upon payment of moderate fees. The enactments against this crime, which punish only the innocent relatives, have led juries in general to find that the act was committed in a fit of temporary insanity.

aft of temporary insanity.

FRIONY, fel'-on-c (Ang.-Nor.), in Law, in its general acceptation, comprises every species of crime which occasioned, at common law, the forfeiture of lands or goods. This most frequently happens in those crimes for which a capital punishment either is, or was, liable to be inflicted. Hence all offences now capital are in some degree or other felony, as well as many other offences which are not punished with death; as suicide, homicide, larceny, &c., all of which are, strictly speaking felonies, as they subject the committers of them to forfeitures. Various derivations of the word have been Ing leionies, as they surpress the commerces a con-forfeitures. Various derivations of the word have been suggested; but the most probable is that given by Sir Henry Spelman, from the Teutonic or German fee, flef or feud, and lion, price or value; felony being thus the pretium feudi, the consideration for which a man gives up his fiel (See Forentures.) Felspar, fel'-spar, in Min., an important mineral, and common constituent of rocks. It is the represen-tation of a family and consists easentially of a double

tative of a family, and consists essentially of a double silicate of a laminy, and comes alkali, or alkaline earth. It forms a principal constituent of granite. Potash felspar is the orthose of the mineralogist, and gives rise to kaolin, or china-clay, by disintegration. Soda felspar is albite, lithia felspar petalite, and lime felspar labradorite. The term is derived from the felspar labradorite. The ter German, and means field-spar.

FEIR, felt (Sax. felt), the name given to the ma-terial formed by uniting and compressing fibres of wool, fur, and other substances fit for the purpose, into a compact body, by what is termed the felting process. This consists in mixing the fibres of the materials employed until they become interlaced or matted together in the form of a soft loose cloth or sheet, which is done by the instrumentality of carding and dolling engines. When this stage in the process has been reached, the cloth is wound on a roller, and has been reached, the cloth is wound on a roller, and carried to the felting-machine, in which the fibres are combined and interlaced still more closely by the action of heat and pressure, until the loose substance is converted into a close, thick material, possessed of great strength and durability. Felt of a fine kind is used for making hats (see Hat MANUFACTURE); and a coarser description is used for table-cloths and carpets. A stiff rough felt is also manufactured for making roofing for already and coarrings for hayring. making rooting for sheds, and coverings for hayricks and cornstacks, as well as for supplying a lining to the copper sheathing applied to the bottom of vessels; and another sort for covering steam-boilers, for which it is well adapted, on account of its properties as a non-conductor of heat. The last-named material is made conductor of heat. The isst-named material is made of the waste woollen cloths used in paper-mills, reduced to a pulp, and beaten together after being put on the boiler in a wet state. It is then allowed to dry, when it becomes stiff, solid, and utterly impervious to heat. All the other different kinds of felt are made

# Femgerichte

ment through crevices in the flooring; they are also tolerably durable, but, on account of the pattern being on the surface of the fabric, the colours are printed on the surface of the fabric, the colours are apt to fade and become obliterated by constant wear. The roofing felt is rendered waterproof by being sosked with a preparation of tar or bitumen: it is sold at a penny per square foot, and forms an excellent substitute for thatch, slates, or tiles for the roots of out-buildings, being impenetrable to rain. It would, however, burn freely, if it happened to catch on fire when in a dry state. Felt of a similar kind is also used for lining wooden buildings and the walls of rooms that are affected by damp. The Americans prepare a thin kind of felted cloth for lining coats and dresses, and felt cloth is used in this country for lining dresses, and felt cloth is used in this country for lining coaches, and for pianofortes, and a variety of other purposes. The process is said to have been invented by the Saracens for making coverings for their tents, and introduced into Europe at the time of the crusades.

FRIUCCA, fe-luk'-ka (Ital.), the largest and fastest description of boat used on the Mediterranean, having a low but graceful and buoyant hull, with a high stem and raking stern, fitted with three masts, lateen sails, a jib set on a small bowsprit, and long powerful oars to assist their progress in those lengthened calms so frequent on the above sea.

Frmale Flower, fe'-mail flow'-er (Lat. femella, Fr. femelle, female; fleur, flower), a term used in Bot. to distinguish those flowers which are furnished with pistils, or female organs, but which have no stamens, or male organs of production.

FEME COVERTE, fam ko'-vert (Fr.), in Law, denotes FIME COVERTE, fam ko'-vert (fr.), in Law, denotes that relationship in which, in consequence of marriage, a wife stands to her husband, being under his protection and influence, and her legal existence being suspended, or at least incorporated and consolidated in that of her husband. Her condition during marriage is thus called her coverture. A married woman cannot are in the civil courts without her husband's consequence and in his name as well as her own neither currence, and in his name as well as her own; neither can she be sued without her husband being made a defendant. The property of a wile is, by marriage, transferred to her husband; and all deeds and acts done by her during her coverture are yold. The done by her during her coverture are void. done by her during her coverture are void. The lauded property of a married woman is, during the marriage, under the administration of her husband, and her personal property is absolutely vested in him. When a wife is deserted by her husband, she may now obtain an order to protect any property that she may acquire by her own industry. The husband is bound to pay his wife's debts contracted previous to marriage, and also to provide her with necessaries during marriage; but he is not chargeable for anything besides necessaries. In some felonies, and other inferior crimes, committed by her through constraint of her husband, the law excuses her, except in the case of treason or murder.

FEMGERICHTE, FEHMGERICHTE, OF VEHMGERICHTE, faim-ger-ik'-ta (from the old (terman fem, punish ment, and gericht, court of justice), was the name of certain secret tribunals which existed in Westphalia, certain secret tribunals which existed in Westphalia, and possessed immense power and influence in the 14th and 15th centuries. These are said by some to have been originated by Charlemagne, but it is more probable that they were relies of the aucient German courts of justice, which continued to exist in Westphalia after they had ceased in other parts of Germany. The Fengerichte first came into notice after the deposition and outlawry of the emperor Henry the Lion, when all law and justice seemed to be set at the deposition and changed in the property including when all law and justice seemed to be set at deflance, and anarchy everywhere prevailed. In such circumstances the secret tribunals took upon themselves the protection of the innocent and defenceless, on the power in a wet state. It is then allowed to dry, when it becomes stiff, solid, and utterly impervious to lear. All the other different kinds of felt are made by smalganiating the materials by the agency of heat, moisture, and pressure. Table-cloths of this material are either embossed, having a raised pattern in one colour on a ground of another hue, or printed in a colour. In addition to being inexpensive, they have the merit of being inexpensive they have the merit of the merit of all Germany, and inspired with saltary terror those whom nothing allow would keep in check. These tribunals soon active would keep in check. These tribunals soon active

833

Though originally established amounted to 100,000. for the support of right and justice, there can be little doubt that they afterwards were frequently made use of doubt that they atterwards were frequently made use of to sarry out party feelings. Any one who had a complaint against his neighbour, which could not be sustained before the ordinary judges, betook himself to the Femgerichte. From the secrecy in which they were involved, little is known regarding their internal organization. The members were called the Wissende, or the knowing ones; and, before being admitted, they must be of blameless life, of the Christian religion, and take a terrible outh "to support the holy Eam and to conceal terrible oath "to support the holy Fem, and to conceal it from wife and child, from father and mother, from sister and brother, from free and wind, from all that the sun shines upon or the rain wets, from all that is between heaven and earth." From smong the Wis-sendes the Freischöffen (free justices) were elected, who were the assessors of the court and executors of its The president of the court was called the sentences. sentences. The president of the court was careful the freignaf (free count). The general superintendence of the whole of the tribunals was in the hands of the lord of the land, who, in Westphalia, was the archield prof Cologne. The chief superintendence, however, was in the hands of the emperor, who was usually, on his coronation at Air-la-Chapelle, admitted a member of the society. The court of a Freigraf was called a Freiding, and the place where it was held a Freiding, the members had certain signs and watchwords, by which they were able to recognize each other, and which were concealed from the uninitiated. Their courts were either open or secret; the former were held by day in the open air, the latter by night in a forest, or in concealed and subterranean places. The process of trial, and the circumstances of judgment, were different in the two cases; the former decided in all civil causes, the latter took cognizance of such as had been unable to defend themselves sufficiently before the open courts, as well as such as were accused of heresy, sorery, rape, theft, robbery, or murder. The accusation was made by one of the Freischöffen, without further proof, declared upon cath that the accused had been guilty of the crime. The accused was then thrice summoned to appear before the secret tribunal, and the citation was secretly affixed to the door of his dwelling, or some neighbouring place, the name of the accuser being concealed. The citation mentioned that the accused was to meet the Wissende at a certain hour and place, and to be conducted by them before the tribunal. Here by an oath the accused might clear himself; but the accuser might also oppose it with his oath and the oaths of witnesses. If the it with his oath and the oaths of witnesses. If the acoused could now bring forward six witnesses in his farour, the accuser might strengthen his oath with fourteen witnesses; and sentence of acquittal did not necessarily follow until the accused had supported his case with the oaths of twenty-one witnesses. The judges were all armed, and dressed in black gowns, with a cowl that covered their faces like a mask. The condemned, as well as those who did not obey the summons, were then given over to the Freischöffen. The first Freischöffe who met him was bound to hang him first Freischöffle who met him was bound to hang him on a tree; and, if he made any resistance, it was lawful to put him to death in any other way; and a knife was left by the corpse, to indicate that it was a punishment indicated by one of the Freischöffen. The punishment, however, was rarely indicated on those who readily appeared, the judges being satisfied with cautioning the defender to redress the wrong he had been guilty of the leadth or grad nutter was raised against these of. At length a great outery was raised against these courts, and in 1461 various princes and cities of Germany, as well as the Swiss Confederates, united in a league to enable all persons to obtain justice by

minations proper to express females in any given

FEMORAL, fem'-o-rdl (Lat. femur, the thigh), in Annata, is applied to parts of or connected with the abigh; as, the femoral bone, or os femoris; the femoral artery, &c. (See TRIGH.)

rough; as, the temoral one, or or perform; the temoral artery, &c. (See Thion.)

Fan, fen (Sax. fen or fenn), is used to signify low land which is wholly or partially covered with water to some depth. The subsoil is always saturated, and the land itself is apt to be overflowed with the discharges of rivers and lakes. The soil of these lands is generally of a deep black colour, and is unusually rich and light to the depth of some three or four feet. As the water often filters down to the subsoil, fen lands produce crops of grass and corn in far greater abundance than lands better situated. Until of late, windmills were used to drain the English fens, as is the case in Holland; but now steam is nearly the sole agent employed for this purpose. The feus in Lincolnshire, Keut, and Cambridgeshire, are the principal instances

Acut, and Cambridgeshire, are the principal matances of this species of land in England.

Fence, fens (from Nor. defender, to prohibit, defended, a term used in Gardening and Husbandry to signify a hedge, wall, ditch, bank, or other inclosure, made around gardens, fields, woods, and other agrarian property, for the purpose of protection or separation. Fences are usually made of paining or split planks, although there are other and various methods in which have an econstructed. In the wild and wountsinous they are constructed. In the wild and mountainous regions of Ireland and Scotland, where wood is very scarce, it is usual to make fences of rough stone walls, put together without any mortar, in order to separate the property of different individuals. In parts of Galthe property of different individuals. It parts of Gat-way, in Ireland, some of these fences, or stone walls, are built in a very efficient and workmanlike mauner, and are very durable, as the stone in many instances is of a soft nature, which is liable to split with a flat surface; in such cases there are many dry walls which present in such cases there are many dry wans which present the usual appearance of those constructed with mortar. A high bank of earth, faced with turf sods, is often sub-stituted for a stone wall when stones cannot be had, and a hedge is then planted on the top of this embankment; thus completing a formidable leap to lovers of ment; thus completing a formidable leap to lovers of the chase in hunting counties. Of all fences, the best which can be constructed is, undoubtedly, a live hedge, when it is properly planted and carefully cut and trimmed when arrived atfull growth; for further infor-mation on which subject, see separate article HEDGE, A sunk fence is one which is planted in a broad, deep ditch, and is not above the level of the ground; so that it is concealed from the risw. A light fource of solit it is concealed from the view. A light fence of split rails or iron, which is erected to keep off cattle from a lawn, and which does not conceal the riew, is termed a "ha ha." When fouces are constructed of branches of thorns and bushes, without stakes, they are called foot hedges; when the branches are interwoven, and rods wattled in at the top, they are termed stake-andedder hedges.

FENCING, fen'sing (from the same root as defence and fence), the art of using skilfully, in attack or self-defence, a sword, rapier, or bayonet; but usually taken to mean address in the use of the second of these weapons. In actual personal combat the rapier is, or more pons. In actual personal combat the rapier 1s, or more correctly was, used, for its employment has gone out with the practice of duelling. In the school of sence the foil is wielded. The foil is a circular or quadrangular rod or blade of pliable highly-tempered steel, blunted and covered with leather at the point, so as to prevent accidents in its practice. In length it varies between thirty-one and thirty-eight inches, and, for the purposes of the art, it is divided into two parts,—the forte, which occupies the half of the blade ending with the hilt, and the faible, which occupies the other half a league to enable all persons to obtain justice by forte, which occupies the half of the blade ending with their means, and to prevent them from seeking it from the secret tribunals. Their influence, however, was not entirely destroyed until the public peace was established in Germany, and an amended form of trial and penal judicature introduced. Goethe, in his "Goetz construction of the mass given an account of the workings of these secret tribunals; but the best historical account of them is by Paul Wigand, "Das Folmgesicht Westfalene," Harmm., 1825.

FERINTIER, fem'-e-mia (Lat. femina, a woman), is the opposite of masculine, and masns pertaining to a woman or women. Words are said to be feminine in grammar when they denote females, or have the termosting the micro denote the half of the blade ending with the hilt, and the faible, which occupies the half of the blade ending with the hilt, and the faible, which occupies the half of the blade ending with the hilt, and the faible, which occupies the half of the blade ending with the hilt, and the faible, which occupies the half of the blade ending with the hilt, and the faible, which occupies the half of the blade ending with the hilt, and the faible, which occupies the other half the hilt, and the faible, which occupies the other half the hilt, and the faible, which occupies the half the hilt, and the faible, which occupies the other half the hilt, and the faible, which occupies the other half the hilt, and the faible, which occupies the other half the hilt, and the faible, which occupies the other half the hilt, and the faible, which occupies the half the hilt, and the faible, which occupies the half the hilt, and the faible, which occupies the other half the hilt, and the faible, which occupies the other half the hilt, and the faible, which occupies the other half the hilt, and the faible, which occupies the other half the hilt, and the faible, which occupies the half the hilt, and the faible terminating with the button. During the patient, and the faible te

#### Fennec

ment in the armour worn by knights in battle; from which circumstance battle-axes and other ponderous weapons of offence were substituted for the sword. When metal casing became somewhat, if not altogether disused, fencing came once more into vogue; and, as all disused, fencing came once more into vogue; and, as all gentlemen wore swords, and quarrels were matters easily got up, it was absolutely necessary that all should have some knowledge of the "fence." The peculiar state of society in Italy made this even more needed than in any other country, and it followed that the Italians became the best fencers in Europe. Spain next found the art necessary, and soon France, in which latter country it created such a favourable impression that a school was astablished for its necessor. pression that a school was established for its prosecunon, and new improvements were found out every day in the science. The early Italian and Spanish schools laught the management of the sword, aided, generally, by the dagger or the mantlet; the shifting of the position of the fencer was also necessary to avoid attack. But since the habit of wearing the dagger and manulet has been abandoned, and the velocity of attack and defence become so great, instruc-tion in fencing has been strictly limited to the foil, and shifting position would be fatal to one engaged. The Italian foil is some thirty-eight or forty inches long, which the French is shorter, being only thirty-four inches, generally, in length. In fencing there are three openings or entrances,—the inside, comprising the whole breast from shoulder to shoulder; the outside, which can be attacked by all the thrusts made above the wrist on the outside of the word; and, finally, the low ports, which embraces the armpits to the hips. In a work of this description it would be impossible to give all the different attacks and defences; the following, however, are the principal:—First, the carte is a guard which is shown by turning the wrist with the nails upwards, and the hand in a line with the lower part of your breast, the arm somewhat bent, the elbow inclining a little to the outside, and the point of your foil directed towards the upper part of your adversary's breast at an angle of about 15°. The thrust, bunge, or longe, is an attack. When at the guard in carte (as just shown), straighton the arm, raising your wrist above your head, keeping the point of your foil still pointing to your adversary's breast, and then thrust out first the wrist and then the whole body by a "lunge" of the right foot some two feet from the of the right foot some two feet from the lunge guard; your left foot remaining firm all the time. The purado is formed by moving your sword over from your guard, when received, obliquely downward to the right about six inches, and opposing the inside of your foil to your adversary's blade. The seconde is shown by holding your nails and wrist downwards, hand opposed outwards; and the blade should form an angle of \$5° with the ground, pointed low. Feints consist in threatening an attack on one side of your foil and executing it on the other. There are many varieties of these, and the best defence is the half-circle parade, which is done by straightening your arm with your wrist on a line with your shoulder, and by a quick motion of your wrist, sweeping the point of your foil from right to left; thus covering your body from head to knee, and obliging your adversary once more to come to position. The calvary sword-exercise is but another instance of fencing applied on horse-back, and the bayonet exercise, in point of fact, may be regarded in the same light.

Fennic, fon'-nek (Vulpes zaarensis; Canis Zerdu

of Zimmermann), belonging to the carnivora, and chiefly found in Nubis and Egypt. This suimal, which has given rise to much controversy, is generally placed by the French zoologists among the foxes; but the observations of Mr. Yarrell led him to pronounce decidedly that the feunec appears to him to belong to the genus Canis, the osteological part of its structure closely resembling that of the dug, and the pupil of the eye being circular. The fennee is of slight build, and seldom measures more than a foot in length, exand seidom nessures more than a foot in length, exiduence of a small portion of organized matter when clusive of the tail, which is fox-like and husby, and is in itself in an actient state of alteration. This active pale fawn, with a slight touch of jetty black at the base and extremity of the tail. Although without though the carnivorous animal, the fennee is especially fond of the fruit of the date-palm, and is especially fond of the fruit of the date-palm, and is are necessary; for instance, the presence of water and said to be able, and frequently to exercise his ability, to

# Fermentation

olimb the lofty trees, and gather the dates. Bruse, who claims the honour of introducing the fennec to zoological science, asserts that it builds its next in trees. In latter times, however, it has been certainly ascertained that it burrows like the foxes. It is of nocturnal habit.

FENNEL. (See FORNICULUM.)

FROFFILE (Over TENIOULUM:)
FROFFILENINI, felf-ment (Lat. feoffamentum, from the verb feoffare or infeudare, to enfeoff, or give one a feud), in Law, is applied to the most audient and solemn method of conveyance. It is defined to be "the conveyance of any corporeal hereditaments from "the conveyance of any corporeal hereditaments from one person to another by delivery of the possession of the hereditaments conveyed, and evidenced by an instrument in writing;" for since the Statute of Frauds, 29 Car. II. c. 3, no valid feediment can be made without a written instrument. The person that so gives or enfectfs is called the feetfor, and the person so enfeoffed is termed the feetfor. And the person so enfeoffed is termed the feetfor, and the person is enfectfied is termed the feetfore feetform, called livery of seisin, without which the feetfee had but an estate at will. This was the actual delivery of a portion of the land or real hereditaments conveyed, as a estate at will. This was the actual delivery of a portion of the land or real hereditaments conveyed, as a twig or a turf, to testify to the reality of the act; or, the parties being within view of the land, the feoffor, referring to it, gave it to the feoffee. This latter mode of delivery was ineffectual unless the feoffee entered into possession during the life of the feoffor. This mode of conveyance may be traced up to the earliest antiquity, and has been common among most rude nations. Livery of seisin was anciently performed before the freeholders of the neighbourhood, who might afterwards bear witness, in the event of any dispute. Afterwards, however, the livery was made in pre-Alterwards, nowever, the livery was made in presence of any witnesses, who attested such delivery in the body or on the back of the deed. Feofiments are now little used, and actual or symbolical livery of seisin is rendered unnecessary by 8 & 9 Vict. c. 106, by which corporeal hereditaments are made to be in corporate and the best of the second of th grant as well as in livery, and which declares that a feoffment shall not have a tortuous or wrongful effect.

Ferm, fe'-re (Lat. ferus, wild), a term employed by Linneus to distinguish the order of mammalia which subsist more or less exclusively upon the flesh of other animals. They have three rows of teeth,—incisors, canines, and molars; unguiculate extremities, without an opposable thumb on the fore foot, but with the power of rotation in the fore-arm. The order of Force

prover of rotation in the fore-arm. Into order of rever-corresponds with the insectivors, and the plantigrade, digitigrade, and pinnigrade carnivors of Cuvier's Car-nassiers. (See Carrivors.) FERE NATURE, fe'-re natu'-re (Lat., of a wild nature), a term applied in Law to wild animals, or such as retain their natural disposition of freedom, as distinguished from such as are tame or domestic. The law holds that a man can have no absolute property in animals feræ nafuræ. There may be, however, a qualified property in these animals, either per industriam, propter impotentiam, or propter privilegium. Per industriam, by a man's reclaiming and making them tame by art, industry, and education, or by so confining them within his own immediate power that they cannot them within his own immediate power that they cannot escape and use their natural liberty. These are a man's property only so long as they remain in his keeping; and if they should regain their natural liberty, his property ceases, unless they have animum reverlend, or are in the habit of returning. Propter impotentiam arises from the inability of the animals; as where such animals burrow or nestle on my land and have young them. I have a unified are written there. there, I have a qualified property in these young ones till they can run or fly away. Propter privilegium; as where a man has the privilege of hunting, taking. and killing them, to the exclusion of others, as in the case of game. (See Game Laws.)

FREMENTATION, fer'-men-tail-shan (Lat. fermentatio),

in Chem.-Fermentation may be defined as a decomposition undergone by organic matter, through the influence of a small portion of organized matter which is in itself in an active state of alteration. This active

#### Ferment Oils

principal kinds of feamentation,—alcoholic or vinous, lactic or batyric, and viscous alcoholic farmentation. When the juices of plants or fruits containing sugar are kept at a temperature of 70° for several hours, the liquor becomes turbid, and small bubbles of gas make their appearance; in common language, it has begun to work or ferment. Under the combined influence of warmth, moisture, and oxygen, the albumi-nous matter has become decomposed, and a change is commenced, which, after it has once begun, continues until the whole of the gas has been eliminated. If the gas is collected, it will be found to consist of carbonic acid only, and on distilling the fermented liquor, a spirit lighter than water passes over, which is readily recognized as dilute alcohol. If the liquor be further examined with a microscope, it will be found to contain a number of oval organized bodies in the form of tain a number of oval organized soules in the form of cells, a full description of which will be found under the head of Ykasr. This yeast is the ferment in this instance, and if dried at a low temperature, it will preserve its power of exciting fermentation for a great length of time. Its power is stopped by several chemical agents; such as the strong mineral acids, the alkalies, excess of sugar, certain corrosive metallic salts, kreesote, carbolic acid, and the essential oils. The change taking place in the sugar may be rendered plain by the following :-

Fruit-sugar. Carb. Acid. Alcohol. = 4CO<sub>2</sub> 2(C,H,O,) C, H, O,

It was considered at one time that the change that bread undergoes during panification was a distinct kind of fermentation. It has now been ascertained that it is only a modification of the alcoholic fermentation produced by the action of the yeast upon the starch and sugar contained in the flour. Luctic fermentation. -Milk may, by being kept at a warm temperature, be converted into a spirituous liquor, by the change of the sugar of milk first into fruit-sugar and then into alcohol by the action of the azotised constituents contained The change which more commonly takes place, when milk is allowed to ferment, is the transformation of sugar of milk into lactic acid. Other animal bodies are capable of effecting the same change in a shorter time; the use of rennet being a familiar example. time; the use of rennet being a lamiliar cample. Caseine, in like manner, is used for a similar purpose; butyric acid being easily made by fermenting sugar, cheese, and chalk together in certain proportions. Viscous fermentation.—Liquore containing sugar often pass into a ropy or thick condition, from the transfor-mation of that body in a mucilaginous substance. No escape of gas takes place, but the liquid loses its sweet The mucilaginous substance has not yet been tasta. thoroughly examined, but its formation is evidently connected with the electrical conditions of the air; examples of which are familiar in the instances of and beers turning thick and sour during a thunderstorm. The change of alcohol into vinegar is not a true fermentation, but a simple absorption of oxveen.

FERMENT OILS .- By submitting certain plants to fermentation, volatile oils are obtained. These products were termed quintessences by the alchemista. Ordinarily they are obtained by the simple process of ordinarily they are obtained by the aimple process of steeping the plant's in water and allowing them to ferment. In Watts's "Dictionary of Chemistry" the following ferment oils are described:—Chemophyllum; sylvestre, wild chervil, common paraley; Chelidonium; augius, the larger celandine; Conium muculatum, common hamlock: Emblosa Centumium; little control of the common hamlock of the common hamlock. mon hemlock; Erythrea Centaurium, little centaury; mon hemlock; Erythrea Centaurium, little centaury; Echium vulgare, viper's bugloss; Erica vulgaris, common heath; Marrulaum vulgare, white horehound; Achillea Millefolium, common yarrow; Plantago, the plantain; Quercus Robur, oak; Sulia pentantra, the willow; Salvia pratensis, meadow-suge; Trifolium fibrinum, the clover; Tussilago Farfara, colt's-foot; Vilis vinifera, the vine; Urtica ureas, the nettle; and diseased amles.

diseased apples. (See FILIORS.) FERN.

FERN. 2007. (See LASTERA.)
FERNIZA, fe-ro'-ni-a, in Bot., a gen. of the nat. ord.
Aurantiacea. The species F. elephantum is a large
tree, growing in India. A kind of gum, closely resembling gam-Arabic, exudes from its stem, and it is very probable that this constitutes part of the East-India

## Ferrocyanogen

gum imported into this country. The young leaves have an anise-like odour, and are used by the native doctors of India for their stomachic and carminative effects. The fruit is known as the elephant or woodapple.

FERRER, fer'-ret (Dp. vret, Fr. furet), Mustela Furo, Linn.).—This well-known animal is a native of Africa, but domesticated in Europe. Its habits are similar to those of the weasel, but more bloodthirsty. Its length is about fourteen inches, exclusive of the tail, which measures about five and a half inches; amout sharp; eyes red and fiery; colour commonly pale yellow, but sometimes partaking of all the colours usual in the weasel kind. In slightness of body and shortness of leg it likewise resembles the weasels. Ferrets are chiefly used to hunt rabbits. Courageous, however, as is the ferret, there is not more than one in ten who is a really good "ratter," or, indeed, that can be induced to enter a rat-burrow. The same timid animal, how-ever, will, without invitation, scamper into a rabbit burrow; and for this very good reason, that whereas, especially if there be many litters of young rats in the colony, the old animals will show desperate fight with the intruder, the rabbits will never, on any chance, turn on it, but rush headlong away. In the pursuit of this latter sport, it was the custom in olden time to see the lips of the ferret together before it was turned into the rabbit burrow, and so prevent it doing anything but sears them out of the hole and into the hands of the watcher at the mouth of it. In old books of "sport," there at the mouth of it. In old books of "sport," there are elaborate instructions as to how the ferret should be held while his lips are being sewn, together with the acrt of needle to be used. The modern system, how-ever, is to muzzle or "cope" the ferret. This is accomplished by the use of two pieces of soft string, one of which is passed round the neck, and the other under the jaws, the four ends meeting at the back of the week, and being there tied. Cold is fatal to the domesticated ferret. It breeds twice a year, the production rauging from six to nine young ones at a litter. Sometimes the female will eat up her young, and in that case she is likely to litter three times in the year. The period of gestation is six weeks. The young are born and continue blind during an entire month, and at three months old are considered fit for "work."

FREEIC ACID, fer-rik (Lat. ferrum, iron), FeO, in Chem.—If one part of scaquioxide of iron and four of Onem.—If one part or sequencine or from an loar or intre be fused together for seme time, a brown mass is obtained, giving a violet-coloured solution, containing ferrate of potash. Ferric acid has never been obtained in a free state, but solutions of the ferrates of the earths may be formed readily by mixing ferrate of potash with these salts.

FREEDOMANGER, fer'-rid-si-dn'-o-jon (Lat. ferrum, iron, and cyanogen), C<sub>12</sub>N<sub>c</sub>Fe<sub>2</sub>, or Fdcy, in Chem., a hypothetical radicle derived from cyanogen, giving rise to salts known as ferridcyanides, a good example of which is met with in the ferrideyanide of potassium, or red prussiate of potash of commerce, which is formed by passing chlorine through a solution of yellow prussafe of potash. Ferridoyanide of potassium is pre-pared in large quantities for the use of the calico-printer. When added to solutions of the persalts of iron, it gives no precipitate; but a very splendid dye, known as Turnbull's blue, is formed by mixing it with a solution of protosulphate of iron. The other ferridcyanides are unimportant.

FERECTANGER, fer'ro-si-dn'-o-jen (Lat. ferrum, iron, and cyanogen), C.N. Fe, or Fey, in Chem., a hypothetical radicle derived from cyanogen, giving rise to salta known as ferrocyanides, of which the ferrocyanide of potassium, or yellow prussiate of potash, may be taken as an example. The salt of commerce is nearly in a state of purity, and is manufactured on an enormous scale for the use of colour-makers and an enormous scale for the use of colour-makers and calico-printers, by heating dried blood, bones, parings of hides, and other nitrogenous animal matter, with an equal weight of carbonate of potash and one-third of fron filings. The carbon, nitrogen, and fron units with the potassium to form a yellow sait, crystallizing in large tabular crystals, containing three equivalents of water. It is very soluble in water, but insoluble in alcohol. Althougu it contains the elements of prussic acid when in solution, yet it is not poisonous. Distilled with sulphuric soid, it furnishes prussic acid

999

# Ferry

in large quantities. It is much used in calico-printing in large quantities. It is much used in calico-printing and solour-making for the production of a fine blue colour, known as Prossian blue, with the persaits of iron. When protosalts of iron are used, a dirty greenish-white precipitate falls down, which constitutes one of the distinguishing tests between the per and proto-satts of iron. It is also largely employed in the manufacture of cyanide of potassium; in fact, it is the only commercial source of that salt. With copper, it forms a characteristic purple-brown precipi-tate, and is used as a confirming test for saits of that metal. With the saits of cobalt it gives a yellowish-

green precipitate.

FERRY, fer'-re (Lat. ferre, to carry), in Law, is a right, arising from royal grant or prescription, to ogry men and horses across a river or arm of the sea for a reasonable toll. The owner of a ferry is bound to keep a boat always in repair and readiness for the use of her Majesty's subjects, for neglect of which he is liable to be indicted. On the other hand, if a ferry be erected so near to an ancient ferry as to draw away its custom, it is a nuisance to the owner of the old one, for which the law will give him remedy. No public ferry can be established without a license from the crown. Bridges have taken the place of ferries to a great extent, and they are only found in the present day over streams running through flat districts, or in places where the traffic is not sufficient to warrant the outlay which would be incurred in erecting a bridge. They are also found at the mouths of tidal rivers, where a bridge would interfere with the passage of where a bridge would interier with the passage of vessels, or its construction would be attended with considerable engineering difficulties. A ferry formerly existed where London Bridge now stands, the profits of which formed part of the endowment of a nannery, which stood on the Southwark side of the water, on, or near, the site of St. Saviour's Church.

FERRY-BRIDGE, a boat or barge of great size and peculiar construction, adapted for the transportation of horses and carriages, as well as foot-passengers, across a stream from one bank to another. The ferry-bridge or floating bridge, as it may be indifferently termed, consists of a level platform laid like a deek on a strongly-built flat-bottomed vessel, square at both ends. This deck or platform is furnished with railings on either side, or bulwarks boarded over, and it has a on either side, or bulwarss boarded over, and it has a lap of timber attached to each end by hinges, which can be raised or lowered by chains. These laps are allowed to rest on the land when the ferry-bridge touches the shore, to afford a safe and easy means of entrance and exit for carriages and horses. Bridges of this description are worked from side to side by means of a chain tion are worked from side to side by means of a chain fastened at either end to posts placed for the purpose in the landing-places. If the distance across he short, the chain is passed round a wheel, which is turned by the ferryman; but in floating bridges placed at the entrance of tidal rivers, where the distance from hank to bank is often considerable, the chain is passed round a barrel or capstan, which is worked by horses or steam power. Ferry-bridges of this description are used to convey vehicles across the river Tamar at Saltash, in Cornwall, and across the Dart at Dartmouth, Devon.

FERULA, fer-a-lá (Lat.), is the classical appellation

mouth, Devon.

FREULA, fer'-u-lā (Lat.), is the classical appellation of a wand or rod. In the time of the Eastern empire, the ferula was the name given to the emperor's sceptre. It consisted of a long stem with a flat head, and it is often to be seen depicted on old medals.

FREULE, fer'-uis (Lat. ferio, I strike), is used to signify a little flat wooden slice or pallet for punishing children at school, by striking them with it on the palms of their hands. It is often applied, too, to a species of cane which is used for the same purpose of castiration.

oustigation.

osstigation.

Fiscennime Verses, fest-sen-nine, were a kind of rude, licentious poetry, common in ancient Italy, and said to have derived their name from the Etrurian city of Fescennium. They were in the form of dialogues between two persons, who satirized and ridiculed each other's follies and vices. They were sung on festive occasions, particularly at weddings, but were distinct from the epithalamia, which were more refined and ragular compositions. The emgeror Augustus prohibited them, as tending to corrupt the public morals.

Firstivals. (See Feasts.)

833

# Feudal System

FESTOON, fes-toon' (Fr. feston).—Htricity speaking, this word means a garland or wreath; but in architecture, sculpture, &c., it is applied to designate an ornament composed of flowers, fruits, and leaves interwoven or twisted together, suspended at each end. Fartcurst, fet-sh-trm, is the worshipping of a fetich. The word fetich is said to be derived from the

Portuguese word frieso, bewitched or possessed by fairies, and was applied by them to the objects worshipped by the negroes of Africa. Hence the term has come to be generally received, and is applied to the ascription of life and intelligence to insminute objects, as stones, carved images, &c. Fetichism, then, is the worship of material substances, a form of idolatry that prevails very extensively among barbarous nations, and especially those of the negro race.

and especially those of the negro race.

Frilox, fet'lok (Ang.-Sax., from footlook), a tuft of hair which grows behind the pastern-joint of most horses; horses of diminutive size, however, have hardly any tuft. The term is now more generally applied to the joint on which the tuft in question grows.

Frud., fude (Ang.-Sax.), denotes a deadly quarrel or enmity subsisting between one tribe or family and another. They formerly prevailed extensively among the northern nations of Europe, and were a combination of kindred to revenge the death of any of their blood against the player and all his race, and were frequently against the slayer and all his race, and were frequently

against the mayer and as his race, and were frequency kept up for many generations.

FRUDAL SYSTEM, fu'-dail sis'-tem, is that constitutional system which was introduced into Europe by the northern nations after the fall of the Roman power, and which has left important traces of its existence in most European countries. The constitutional fall had be a first and the military relies of tion of feuds had its origin in the military policy of the Goths, Huns, Vandals, and other norther nations, who overran Europe at the declension of the Roman empire. The term fend is of very doubtful derivation, but most probably it is formed from the Teutonic Jes or feh, wages or pay for service, and odh or od, property or possession; a feud then being the property or possession given as wages for service. In order to or possession given as wages for service. In order to secure their newly-acquired possessions, and at the same time to reward their deserving followers, the conquering generals were wont to allot large districts, or parcels of land, to the superior officers of the army, and these were by them dealt out again in smaller allotments, or parcels, to the inferior officers and soldiers. The condition annexed to these holdings allotments, or parameter and the second to these holdings soldiers. The condition annexed to these holdings was that the possessor should do service faithfully, both at home and in the wars, to him by whom they were given; for which purpose he took the oath of fealty (paramentum fidelitatis), and in case of the breach of this condition and oath, by not performing the stipulated service, or by deserting the lord in battle, the lands were again to revert to him who maked them. The ownership of the land, therefore, battle, the lands were again to revers to man granted them. The ownership of the land, therefore, properly remained in the hands of the superior, and the superior of the superior of the superior of the superior was resumable by him at pleasure, probably at first was resumable by him at pleasure, or at least on the death of the holder; but, in most countries, lands soon came to assume an hereditary character, the rights of the superior, on the death of a vassal, being confined to the exaction of certain dues from his son and successor, as a consideration for confirming to him the feud which his father had held Where the land descended to a female, the superior was entitled to control her marriage for the purpose of procuring a trustworthy vassal, a privilege which, of procuring a trustworthy vassal, a privilege which, like the other, was afterwards converted into a pecuniary payment. According to this system, every receiver of land, or feudatory, was bound, when called upon, to serve his immediate lord or superior, and to do all in his power to defend him. Such lord or superior was likewise subordinate to; and under the command of, a higher superior or lord; and so on upwards to the prince or general himself. The several lords were also reciprocally bound in their respective gradations to protect the possessions they had given. Thus the coanection between lord and vassal was made to wear all the appearance of a mutual inter-Thus the connection between lord and vasual was made to wear all the appearance of a mutual interchange of benefits,—of bounty and protection on the one hand, and of gratitude and service on the other. In this way the feudal connection was established, and an army was always at command, ready to fight in defence of the whole, or of any part, of the newly-acquired country. The wisdom of these measures

became evident to the other princes of Europe, and many of them who were independent adopted this system as a means of strengthening their power, parcelling out their royal territories, or persuading their subjects to surrender up and retake their own isnded property under the like feudal obligations of military featly. Thus the foudal constitution, or doctrine of them the strength of the Western world; and tenure, extended itself over all the Western world; and tenure, extended itself over all the Western world; and the feudal laws drove out the Roman, which had hitherto universally prevailed. This system was adopted in most countries of Europe from the 9th to the end of the 13th century; but it differed in various particulars in the different countries. Though there can be no doubt that feudal principles prevailed to a considerable extent in the polity of the Saxons in England, yet it was only when that country was conquered by the Normans that it was regularly established. in some respects, however, the system of feudalism established in England differed from that of France, from which it was taken. One of these was that the king was the universal lord and original proprietor of all the lands in his kingdom, and that no man could possess, or hold, any part of it, but what was mediately or immediately derived from him, to be held mediately or immediately of him upon feudal service. Hence the Conqueror introduced the practice of compelling those holding mediately as well as immediately of himself to swear fealty to him; and thus the inferior vassals were under two oaths,—the one of fealty to the king, the other of fealty to their immediate superior. It has been remarked, however, that when the two interests came into collision, the vassal rarely failed to obey his lord rather than his king. The wardship, or guardianship of the tenant during minority, which implied both the custody of his person and the appropriation of the profits of his estate, was another feature of English feudalism which did not exist in the French. In England, the whole country was divided into about 60,000 knights' fees, the tenant of each of which appears to have been obliged to keep the field at his own expense for forty days, whenever his lord chose to call upon him. For smaller portions of land, emaller periods of services were due. Every great smaller periods of services were due. Every great tenant exercised a jurisdiction, civil and criminal, over his immediate tenants, and held courts, and adminis-tered the laws within his lordship, like a sovereign prince. The existence of manor-courts and other small jurisdictions within the kingdom is one of the sman jurisdictions within the kingdom is one occurs features of the feudal system. The land eschested to the lord when the tenant left no beir, and it was for-feited to him when he was found guilty either of a breach of his oath of featty or of felony. There were breach of his oath of fealty or of felony. There were also fines payable to the lord on certain occasion, as well as aids, reliefs, &c. The vassal had also to attend the lord's courts, sometimes to witness, and sometimes to take part in, the administration of justice; in battle, he was bound to lend his horse to his lord if dismounted, to keep to his side while fighting, and go into captivity as a lostage for him when taken. It was a breach of faith to divulge his (the lord's) counsel, to conceal from him the machinations of others, to injure his person or fortune, or to violate the sanctity of his roof.

FEU DB JOIR fulde(r)-zhwan a term derived from

sencity of his root.

FEU DE JOIE, fu'-de(r)-zhwaw, a term derived from
the French, and applied to bonfires lighted in public
places and in villages, to celebrate any important event
or feative season. These feux ds jois were known
amongst the Romans, as Romulus instituted a species of
them, particularly in honour of the building of the city
of Rome. The term feu de jois is also often applied to
a salute fired on any particular occasion, in celebration
of festivals, &c.

of festivals, &c.

Fruillars, five'-yöns, in Ecol. Hist., is the name of a reformed branch of the Cistercian order of monks. It was founded by Jean de la Barrière, abbot of the Cistercian monastery of Feuillans near abbot of the Cistercian monastery of Feuillans near laxivy of discipline that then prevailed, introduced a much more austere mode of life. He soon found many followers, and they were declared independent by Sixtus V. in 1696. They were afterwards divided, in 1690, into two congregations by Pope Urban VIII., who separated the French from the Italians, and gave them increased heat and 1630, into two congregations by Pope Urban VIII., who separated the French from the Italians, and gave them without the payent is said to be without fever; two generals. They practised great austerities, going barefoot, and living only on heads. The cloister of the seven course as a particular disease of itself, barefoot, and living only on heads. The cloister of the cister of the vascular system and the condition of the blood itself. When, indeed, the term fever is used in a general sense to denote a general disorder consequent upon or symptomatic of come local disease, then increased heat and losso, into two congregations by Pope Urban VIII., who seems the french from the Italians, and gave them

this order at Paris gave name to the celebrated political club which, during the French revolution of 1789, held its meetings there. It was founded in 1790, by Lafayette, Sièves, Larochefoucauld, and others, and was intended to support the constitution against the ultra party. When Count Clermont Tonnerre was elected president of this club, a popular insurrection broke out against it; and on the 28th of March, 1791, the Assembly in the cloister was dispersed by the mob.

FRUILLERON, fully-we ton(q) (Fr.), is properly a small

The Liketon, full-lye ton(g) (Fr.), is properly a small leaf, but is generally applied to that part of a political newspaper which is devoted to news of a non-political newspaper which is devoted to news of a non-political newspapers which is commonly, in continental newspapers, to be found at the bottom of the page. The feuilleton is an invention of the Journal des Débats, which, in 1800, introduced the system of giving literary criticisms in this form. Afterwards the bolles-lettres element began to prevail in the feuilleton, and Jules Janin became the acknowledged king in this class of literature. In the years immediately preceding the revolution of February, whole romances were spun out in the feuilleton; and in particular, the Constitutionnel made large sums from the social romances of Engene Sue, which it first published in this way. The French system has been imitated in England and Germany, though not to the same extent, and with less marked success. In fact, the feuilleton propers seems only to be in its natural element in France. The language and the character of the people are peculiarly fitted for imparting that grace, point, neatness, and vivacity that give a peculiar charm to the higher productions of this class of literature, and which draw additional power from their many-sidedness and frequent changes.

Faver, fe'-ner (Lat. febris, from ferres, I am hot), in Med., is the name given to a very numerous and important class of maladies, which, however diversified in their several characteristics, still present something in common in their general features. It is impossible to give a general definition that will apply to all the different varieties and forms of this class of diseases; but, among the features that are almost always present are spontaneous and painful lassitude, weakness of the corporeal and mental faculties, alterations of the secretions, altered animal heat, quickened circulation, and increased thirst. One of the earliest and most constant symptoms of fever is lassitude, and is usually attended by a painful or irksome sensation in the back and limbs. It is manifestly referable to a depressed and limbs. state of the nervous energy, more particularly as regards the organic nervous system. To this depressed state of the nervous energy that weakness of the corporeal and mental powers which often precedes the evolution of the disease, and always in some degree attends it, is to be attributed. It is usually manifested more in the corporeal than in the mental faculties, particularly at first. Some of the mental powers are more affected than others; as attention and the reasoning faculties, than the imagination. Alterations of the secreting and excreting functions are among the earliest and most constant, and most important phenomena of fever. The exhalations from the lungs and skin are the earliest and most affected; but, besides these, the salivary, gastric, hepatic, intestinal, and urinary secre-tions, are more or less altered as respects either tions, are more or less altered as respects either quantity or quality; the alterations being somewhat different in different types and states of fever. The temperature of the body is also variously affected in the different stages. At first it is usually below, but it soon after rises above the normal condition, and is generally accompanied with a certain morbid accompanion which it is difficult to describe. Onickned sensation which it is difficult to describe. Quickened circulation has generally been regarded as one of the most essential symptoms of fever; but this feature is not constantly present, at least in some stages of the disease, and it is often of less importance than other states of the vascular system and the condition of the blood itself. When, indeed, the term fever is used in a general sense to denote a general disorder consequent upon or symptomatic of some local disease, and not a primary or idiopathic disease, then increased heat and and are always associated with others which are usually more important. Thirst is seldom wanting in fever, except occasionally in its advanced state; and the appetite for food is also diminished or entirely shoulshed. Medical men distinguish various stages or periods in the course of fever which are characterized by features more or less marked; sa, (1) the formative or precursory stage, the earliest stage of the disease, being sory stage, the earliest stage of the disease, being characterized by those early changes which are productive of those which constitute the developed disease; (2) the stage of invasion, when the earlier symptoms of the disease itself manifest themselves; (3) the period of excitement or reaction, when fever in its more literal sense begins, and manifests its specific more hteral sense begins, and maniests its specime form; (4) the period of orisis, when a sudden change takes place in the course of the disease, known as the crisis; (5) the period of decline which succeeds the crisis, and which passes into the (6) last stage,—that of convalescence. Fever presents itself in a great variety of forms, the simplest of which is what is termed ephemers, or one day's fever, because it seldom lasts above twenty-four hours. It begins with chilliness or rigor, paleness, weariness, and a frequent small pulse, withindifference to food. These symptoms are followed. in half an hour or a little more, by heat of skin, a flushed face, frequent hard pulse, occasionally headache, and a peculiar sense of fatigue, restlessness, and slight sore-ness of the muscles. After this state has continued for peculiar sense of fatigue, rectiessness, and sugar sorress of the muscles. After this state has continued for twelve or eighteen hours, or at most twenty-four, gentle perspiration breaks out, under which, in the course of little more than an hour, every essential symptom vanishes, leaving only a feeling of exhaustion and muscular debility. This is the simplest and slightest form of fever; and though, on account of its sugness form of rever; and though, of seconds of its shortness, it seldom attracts much notice, yet it is by no means uncommon in this country, particularly during the spring months. If such an affection be supposed to recur several times every other day, with an interval of comparative health in the intervening days, a clear notion will be formed of intermittent fever in its meet frequent and characteristic form,—the tertian; and from the tertian may be derived all the other forms of intermittent fever. If, in the next place, the febrile state be conceived to be reinforced twice a day, or oftener, by a fresh attack of rigor or chilliness, with subsequent reaction before the pre-existing pyrexis had materially subsided, a distinct conception may be formed of remittent fever. From the remittent fever most nosologists deduce the only remaining primary type,—continued fever, by supposing the remissions to become gradually less and less distinct; but others, with perhaps more reason, regard them as ephemers, merely prolonged to such a duration as that its several stages occupy between four and nine or eleven days. In accordance with these remarks, what are known as primary fevers may be divided into three classes. continued, intermittent, and remittent fevers. continued, intermittent, and remittent fevers. The first class comprises synocha, or inflammatory fever; synochus, mixed, or nervous fever; and typhus, or adynamic fever. Intermittent fevers are divided into tertian, quotidian, and quartan; while remittent fevers comprise the marsh remittents, and probably also the comprise the marsh remittenes, and probably also the veillow fever. Besides primary fevers, there are the irruptive class of fevers, comprising the small-pox, measles, and searlet fever; and the irritative fevers, comprising gastrio fever and gastro-intestinal, remittent, and hectic fever.—Ref. Copland's Dictionary of Medicine.

Fians, fe'-are, in Scotland, are the annual average prices of grain, determined in each county so as to regulate crown duties, ministers' stipends, and the rents of agricultural subjects, where these are made to de-pend upon the price of grain. The derivation of the word is uncertain, and, according to Dr. Jamieson, it is of Gothic origin. They were originally instituted in Scotland for the purpose of ascertaining the value of the victual or grain-rents payable to the crown, and were at first determined annually by the exchequer, upon returns made of the prices of grain by the sheriffs of the different counties. Afterwards it was left to the sheriffs themselves to determine the flars prices in their several counties, who summoned a jury for that purpose. Fiars appear to have been struck in Scotland as early as the middle of the 18th century; and the form of procedure is regulated by an act of

sederunt, dated 21st December, 1733, and renewed 29th February, 1728. This act requires I the sheriffs of Scotland and their deputies yearly, between the and 20th of February (O. S.), to summon before them a competent number of persons living within the sheriffdom who have knowledge and experience of the prices and trade of victual in these bounds, and from them to choose fifteen men, whereof not fewer than them to choose fifteen men, whereof not fewer than eight shall be heritors, to pass upon the inquest, and return their verdict on the evidence underwritten, or their own proper knowledge, concerning the flare of the preceding crops of every kind of vintual of the product of that sheriffeum; and the said sheriffs and their deputies shall to the same time and place unto which the jury is called, also summon the properest witnesses, and adduce them and all other good evidence, before the said jury, concerning the price at which the several sorts of victual have been bought and add cenedially since the lat of November immed. and sold, especially since the 1st of November immediately preceding until that day;" "and any persons then present may in open court and no otherwise, and observing due order and respect, offer information to the jury concerning the premises and concerning the evidence adduced or that might be adduced before them." In Scotland a great many contracts are regulated by the flars prices. In letting farms on lease, it is often arranged that the whole, or a certain portion it is often arranged that the whole, or a certain portion of the rent, be paid in grain, or according to the value of so many boils of wheat or barley, as fixed by the flars; so that in the event of a greatfall of prices during the currency of the lease, the tenant should not suffer; and, on the other hand, that the landlord should resp a fair share of the advantage of a rise of prices. like manner many foundations, the stipends of the es-tablished church clergy, the salaries of parochial schoolmasters, &c., are made to depend more or less upon the flars prices. It is the interest, therefore, of those who have to pay, that the flars be struck as low as possible, and of those that are to receive, that they be as high as possible; and hence they are determined with a considerable degree of accuracy, generalized. rally, it is believed, rather under than over the mark. It is thought, however, that the period fixed for taking the averages is too early, there not being much of the grain of the previous crop brought into the market by that time.

Firs, f'-dt (lat., let it be done), in Law, denotes a deree, a short order or warrant of some judge for making out and allowing certain veccasion.

Filt, in Bankruptcy, denoted the authority of the lord chancellor to a commissioner of bankrupts to proceed in the bankruptcy of the trader therein men-tioned. It was abolished by 12 & 13 Vict. c. 106, and

a petition for adjudication substituted.

a pectaon for adjudication substituted.

Fiber, \$f^\* br (Lat. fbru), a term applied to animal, vegetable, or mineral substances which have a stringy or thread-like structure. In a general sense, it includes the hair and wool of quadrupeds, the threads enwrapping the ocooons of silkworms, &c., the fibres of the leaves of plants and of their inner bark, the elongated cells or hairs connected with the seeds of plants, and the ordinary materials used in making cordage and textile fabrics. Mineral substances are called fibrous in structure, even when it is impossible to detach the apparent fibres. The only fibrous minerai which has been used for textile fabrics is Amianthus, a variety of asbestus; but that only to a very limited extent. The animal substances used are divided into extent. The animal substances used are divided into two classes; the first including hair and wool, and the second the silk of occoms. Nearly all textile fabrics are made from the first, and the wool of the sheep is the most important division of the class. The hair of the goat, alpaca, camel, bison, and other animals, is also used. The hair of most animals is, however, in general, too short to allow of its being used for textile manufacture. The vegetable kingdom yields the largest number of useful fibres, which are obtained trom natural orders very different from each other. The serogeneous or cryptogamous plants do not, however, afford any. From erogeneous plants, fibres are obtained from the inner bark, as in the case of flax, hemp, &c., and from the hairs of the fruit, as in cotton. In endogeneous plants, the fibre is sometimes obtained from the fruit, as in cocca-mt fibre. The spathe of some palms is also used.

Some of the slander palms called from natural orders very different from each other.

## Fibrin

rattans, and the bulrush, &c., are much used, on account of their fibrous nature, for wicker-work, chair-bottoms, and similar purposes. The most valuable fibres obtained from endogenous plants come from the leaf or leaf-stalk. The fibres of the bark of exogens are readily separated, usually by steeping or continually moistening with water. As this process injures the colour of endogenous substances, the fibres are generally separated by beating or passing between rollers. Fibres obtained from fruits, as cotton fibre, like the wool and hair of animals, exist naturally in a separate state, and only require to be collected and cleaned. Amongst the useful vegetable fibres, those of flax, hemp, and cotton have long held the first place. The writing ladditions of late warm have heaven have long held the state of the warm have heaven have been New Zerosen and the state of the state principal additions, of late years, have been New Zealand flax, jute, Sunn or Sunn hemp, coir, Pits flax, Abacs or Manilla bemp, China grass, and some others. One of the most important uses of vegetable fibre is in the most important uses of vegetable fibre is in the manufacture of paper. Among exogenous plants whose fibres are used for economical purposes, are a species of gossypium which produces cotton; the Bombar villoam, which produces silk-cotton, or vegetable silk; and the Asclepias syriaca, producing the silk-like down of Virginian silk. These three substances are obtained from the fibres of the fruit. Those obtained from the inner bark include the following:—several species of Hibiagus, producing Deckapes hemp: the species of Hibisous, producing Deckanes hemp; the Corchorus olitorius, from which jute is obtained; the Linum usitatissimum, producing flax; several species of the Crotolaria; together with other leguminous plants, producing Sunn, Jubbulpore hemp, &c.; several species of Bohmeria, one of which produces China grass fibre; the Cannabis satica, producing hemp; and the inner bark and roots of some species of pine and fir. Among the endogenous plants from which fibres are obtained, are the Phormium tenax, yielding New Zealand flax; Agave americana, yielding Pita flax; some species of Musa, from the leaves of which are obtained Abaca or Masil, the men and alphabetic fibre are all the contractions. Manilla hemp, and plantain fibre; several species of Bromelia, from which are obtained pine-apple fibre, &c.; the husk of the cocos-nut and the fibre of the stem yield coir; and mata, chair-bottoms, and other important articles in general use, are obtained from the libre yielded by the leaves of the cotton-grass and other species of the nat. ord. Cyperaceæ (which see).

Figure, fi-brin (from Lat. fibra, a thread), one of the constituents of the blood, and of muscular tissue. It

contains, according to Mulder,—carbon 52.7, hydrogen 69, nitrogen 15.4, oxygen 23.5, sulphur 1.2, phosphorus 03. It occurs in two states,—liquid in the animal organism, and solid by spontaneous coagulation, as soon as it is removed from the living body. It is consome as the removed from the name body. It is contained in blood in a liquid state, in the proportion of 25 parts to 1,000, and coagulates in a very short time after the exposure of blood to the sir. It constitutes a large portion of muscle, arranged in bundles of fibres; whence its name. According to Liebig, it is found in the juices of plants and in the gluten of wheat. Mulder looks upon fibrin as a compound con-

wheat. Mulder looks upon fibrin as a compound containing protein. (See also PROTEIN COMPOUNDS.)
FIBULA. (See LEG.)
FICOIDER, fi-loi-de-e (Lat. ficus, a fig), in Bot., a synonyme for Mesembryacca (which see).
FICTION, fik-shun (Lat. fictio, from finge, I feign), in Lit. (See NOVEL, ROMANCES.)
FICTION OF LAW (Lat. fictio juris), is a supposition of law that a thing is true, without inquiring whether it be so or not, that it may have the effect of truth so far as is consistent with equity. They are common in the Roman law, and are not unknown in that of England. The fictions of the Roman law apparently had their origin in the edictal power, and they were devised for the purpose of providing for cases where vised for the purpose of providing for cases where there were no legal provisions. Fictions are resorted to in order to avoid a special hardship, or to remove some unexpected difficulty not provided for by the law. Their existence supposes a defect, which it is the business of legislation to remedy; and of late years many of them have been removed from our laws; years many of them have been removed from our laws; as in the proceedings in ejectment (which see). Fictions must be framed according to the rules of law, and not what is merely imaginable; and there ought to be equity and possibility in every legal fiction. "These fictions of law," says Blackstone, "though at first they may startle the student, he will find, upon 830

#### Fidei Commissum

further consideration, to be highly beneficial and useful; especially as this maxim is ever invariably observed, that no flotion shall extend to work an injury; its proper operation being to prevent a mischief, or remedy an inconvenience that might result from the general rule of law."

Flous, N-kee (Lat., a fig), in Bot., a gen. of the nat. ord. Moraceæ, consisting of trees and shrubs abounding in a milky juice. The most important species is P. Carica, the fig-tree, supposed to be a native of Asia Minor, but now found in all the southern countries in National Conference. minor, but now yound in all the southern countries in Europe. The fruit is termed a syconus (which sea), and is eaten green, and dried as a luxury in some countries, and as a common article of food in others. The finest dried figs are imported from Turkey, and are sold in bulk at prices varying from 20s. to 50s. per cwt. In consequence of their nutritive, emollient, damplearly and luxeling properties they are frequently. demulent, and laxative properties, they are frequently employed in medicine. The fig-tree is cultivated in Britain, but not extensively. It is only in very warm situations that it will ripen its fruit in the open air, even though trained against a wall. When grown in houses built on purpose for it, the fig-tree is remarka-bly prolific. This fruit-tree is the jeenah of the Bible.

BANYAN-TREE.

by the Hindoos. Its branches produce long shoots, or acrial roots, which descend to the ground and pene-trate the soil; so that, in course of time, a single tree becomes a vast umbrageous tent, supported by nu-merous columns. No fewer than 350 stems, each equaling in bulk the trunk of a large oak, and more than 3,000 smaller ones, have been counted in one example. The poet has thus described this marvel of the vegetable kingdom:—

" Branching so broad along, that in the ground The bending twigs take root; and daughters grow About the mother-tree; a pillar'd shade High over-arch'd, with echoing walks between. There oft the Indian berdsman, sbunning heat, Shelters in cool, and tends his pasturing herds At loopholes cut through thickest shade."

The fruit of the banyan is of a rich scarlet colour, and about the size of a cherry; it is eaten by the monkeys, which live with birds and enormous bats in the thick forest of branches. The bark is a powerful tonic, and is much used by the Hindoo physicians. The white glutinous juice of the tree is used to relieve toothache, as an application to the soles of the feet when inflamed, and for making birdlime. F. elastica, also a native of India, yields an inferior kind of caoutchouc, F. Sycamorus, the sycamore fig. is said to have yielded the wood from which mummy-cases were made.

FIDDLE. (See Violin.)

Fidnic Commissus, flate's kom-wis'-swis (Lat., committed to the trust), in the Roman law, denotes something given (usually by will) to one, in confidence that he will convey it or dispose of it for the good of another, The obligation was not created by words legally binding, but by words of request; as volo (I wish), peto The fruit of the banyan is of a rich scarlet colour, and

(I ask); and hence, originally, there was no legal means of enforcing its fulfilment till the time of Augustus, when a prestor was appointed whose sole business it was to see to the fide commissa. The person intrusted with the property was called fiducturing, and the person to whom it was intended to be conveyed, fidei commissarius. Fidei commissa were either particular or universal, the former being the bequest of a particular subject, the latter of the whole estate. They seem to have been introduced in order to evade some legal restriction, and to give the inheritance or a legacy. legal restriction, and to give the inheritance or a legacy to a person who was either incapacitated from taking it directly or who could not take as much as the donor the directly or who could not take as much as the donor wished to give. In some parts of the continent, as Germany and Holland, the fidei commissa form an important feature in the conveyance of heritable property, resembling our laws of entail (which see);—a person receiving the use of certain lands during his life, upon condition of transmitting them unimpaired, in a certain line, after his death.

Fig. (See Feudal Syrenm.)

FIELD, feeld (Ger. feld), in Agr., a portion of land inclosed by a fence, or rendered distinct by some line of separation, and set apart either for tillage or pas-ture. The term "field" was, in ancient times, applied ture. The term "field" was, in ancient since, approach in Britain to the lands under culture by the plough; its signification was consequently very comprehensive, as, until within the last two centuries, all land cultivated with the plough was suninclosed. Afterwards, when farmers portioned off and subdivided a part of the lands when farmers the inclosed nortions were called near the farmyard, the inclosed portions were called fields; the more distant portion, which remained open, was called open field or common field; while grass ands uninclosed were called commons. At the present day, in the improved state of agriculture, every farm is divided into fields, either by simple lines of de-marcation, which are sufficient when no animals are to be grazed on the farm, or by lines of separation which will act as fences; such as walls, hedges, ditches, &c. In all farms, every field has a distinguishing name. Without a regular fixed division of arable lands into fields, it would be next to impossible to conduct a rotation or succession of crops. When space is an object, and the grass lands of a farm are used for the grazing of them; of sheep, it is generally the custom to separate the fields by light netting, or hurdles, scarcely visible at a short distance. If this plan were more generally adopted with regard to the dividing-lines of fields, from a tenth to a fifth would be added to the contents of the greater number of corn farms. The same arrangement also saves considerably the first cost and the annual expense incurred, in order to plant hedges or build

expense incurred, in order to plant hedges or build walls, and in keeping them afterwards in repair.

FIELD ALLOWANCE, a daily amount of additional pay given to officers in the British army in consideration of the extra expenses entailed on them by reason of their service in the field. There are two different sorts of field allowances,—ordinary and extraordinary. The ordinary allowance ranges from £1. 10s. for a field officer to 1s. per diem for a subaltern: this is given for service when in camp at home and when on service in the colonies. Extraordinary allowance is only vice in the colonies. Extraordinary allowance is only allowed when troops are really in the field of action in actual warfare. No officer receives this unless present with the army in the field.

with the army in the field.

FILDFARE, feeld-fair (field and fare, from Sax.
faran, to go), (furdus piralis, Linn.), a migratory
bird, appearing among us about the beginning of
November and departing at the end of April. They
seldom breed in this country. It is about ten inches
in length, and of the following colours:—head, hind
neck, and wings, grey; fore part of the back, clestimit;
space before the eyes, brownish black; fore-neck and
breast, reddish yellow; over each eye a whitish line;
feathers tipped with a brownish triangular spot; those
of the sides with large dusky spots, and margined with of the sides with large dusky spots, and margined with white; lower wing-coverts and axillary feathers, pure white. In Poland, Russia, and Austria, it is found throughout the year. It builds its nest in lofty trees, and feeds on worms and various berries.

FIELD-GLASS, a species of telescope, used for the purpose of observing the movements of armies and operations during a military campaign. Further information respecting this instrument will be seen under the separate head of TRLESCOPE.

FIELD-MARSHAL, feeld-mer-shall (Ger. feld-merechall) the highest military rank that can be bestowed in the British army, and which is occasionally conferred on general officers for distinguished services in the field, and on princes of the blood royal in virtue of their position and connection with the sovereign. It is rather a title of honour in the British service than one rather a title of honour in the British service than one which implies any particular duty to be discharged by the holder, like those of commander-in-chief, general of division, general of brigade, &c. The title, in its present form, is copied from that of feld-mareshall in the Prussian and Austrian services, which was derived from the French term mareshal de camp, given to officers who performed, in former times, duties that were similar to some of those now discharged by the heads of the commissariat department and military train. The rank itself is of old standing. The supreme command of the English army was originally intrusted to a nobleman styled the lord marshal or each marshal of England; but when this office was made an hereditary appendage to the dukedom of Norfolk, it had sed to convey military rank, and marshals of the ceased to convey military rank, and marsnas of the army were appointed when occasion required. There arer at present (1862) seven officers of this rank in the British army: his majesty the king of the Belgians, Viscount Combermere, and Lord Seaton, who are field-marshals of some standing; and H.R.H. the duke of Cambridge, commander-in-chief; General Blake-ney, Lord Gough, and Lord Clyde, who were made field-marshals on Nov. 9th, 1862, when the Prince of Wales attained his majority. Wales attained his majority.

FIELD OFFICERS, in Mil., are such as are competent to command battalions,—as majors, colonels, and lieutenant-colonels; and the term is applied in contrast to those who can only take company duties, such as captains and lieutenants.

FIELD OF VIEW, in a telescope or microscope, means the space within which objects are visible when the focus of the instrument has been properly adjusted to

locus of the instrument has been properly adjusted to suit the sight of the person using it.

Field Spaniel.—This class of dog has very long hair in some parts; it is generally white, with large brown, liver-coloured, or black spots of irregular size and shape. The noze is sometimes cleft, and the ears

FIRLD SPANIEL.

are very long and pendulous, and covered with long hair like its body. The race of spaniel dogs was im-ported originally from Spain; whence their name. The field spaniel is used for shooting in field sports, like its congener, the setter.

FIRLD SPORTS are diversions in the field in pursuit of FIRLD SPORTS are diversions in the field in pursuit of game, &c.; as hunting, shooting, fishing, and coursing.
FIRLD TRAIN, a department of the Royal Artillery somewhat resembling the commissariat of an army. On it devolves the duty of the safe-custody of stores and ammunition, and the forwarding of the same to the base of operations in the field. A regular staff of men and commissariat is kept up in the field train for the purpose of these duties being satisfactorily performed. FIRID-WORES, military works thrown up by an army when hesisging a fortress or town; also those works erected by the besieged for the purposes of defence. Trenches, rife-pits, &c., like those constructed by our army in the Orimea, are instances of one class of field-works.

of field-works.

FIREDING COURTS, feet-ding, were certain petty courts established among early Gothic nations for the purpose of rendering speedy justice in small matters. They were so called because there were four of them established in each superior district or hundred.

FIREL FACIAS, field in fisiched dis (Lat., that you cause to be made; samally contracted fife), in Law, is a judicial writ of execution that lies where judgment is had for dish or damages recovered in the queen's courts. It is a command to the sheriff to levy the data and depresses on the goods and chattels of the debt and damages on the goods and chattels of the defendants, and takes its name from the words of the writ, quad fleri facius de bonis et catallis. This writ is to be sued out within a year and a day after judgment, or the judgment must be revived by a scire facias. This writ lies as well against privileged persons, peers, &c., as other common persons; and against executors and administrators with regard to the goods of a deeased person. The sheriff may not break open any outer doors to execute this writ, but must enter peaceably, and may then break open any inner doors to take the goods. And he may sell the goods and chattels of the party against whom the writ is issued, including agan his actuar for warm as the goods and considers of the party against whom are with it issued, including even his estate for years or his growing crops, until he has raised enough to satisfy the judgment. The sheriff, however, cannot lawfully sell off goods lying upon any premises demised to a tenant, unless the landlord be first paid his rent due before the execution, to the extent of one year's arrears, neither car he carry off, or sell for the purpose of being carried off any straw, hay, manure, or the like, from any lands let to farm, in any case where, by the covenants or agree prohibited between landlord and tenant. By 14 & 15 Vict. growing crops seized and sold in execution by Vict. growing crops seized and sold in execution by the sheriff are, nevertheless, liable for rent becoming due after such seisure and sale, so long as they remain on the lands. By 1 & 2 Vict. c. 110, money, bank-notes, bills of exchange, and other securities, may be taken under a writ of  $\beta_1 \rho_2$ . Under 8 & 9 Vict. c. 127, all personal goods and chattels can be taken, excepting wearing apparel to the value of £5. If the sheriff seize the goods of a stranger, he will be liable in damages. A  $\beta_1 \rho_2$  may be issued in chancery suits for the purpose of obtaining satisfaction of any neumany demand, under a decree or order of the suits for the purpose of obtaining satisfaction of any pecuniary demand, under a decree or order of the court. A flori fucias de bonis ecclesiasticis is a writiesned when the defendant is a beneficed clerk having a lay fee, and addressed to the bishop of the diocese, requiring him to attach the ecclesiastical goods and chattels of the defendant in satisfaction of the

FIRRY CROSS. (See CRANTABA.)
FIRA. (See FIRRI FACIAS.)
FIFA. (See FIRRI FACIAS.)
FIFE. fife (Fr. fifre), a wind instrument of music resembling a small flute in its form and method of performance, seldom having any keys, and never more than one. Fifes are of three kinds, called respectively A. B. and C. They are made from ten to sixteen inches in length, with or without a joint. The B files are the longer and lowest in tone, while those tuned to the key of C are the shortest and highest, and are to the key of the used: they have a compass of two octaves. When employed for military purposes, or open-air performance, the life is a very pretty as well as useful instrument; but its tone is too harsh and acute to be pleasant in chamber music.

acute to be pleasant in chamber music.

Fiftenery, ff-teenth' (Sax. fffyntha), was the name of a tribute, or imposition of money, anciently laid upon cities, boroughs, &c., throughout the realm. It was so called because it amounted to a fifteenth part of that which each city or town was valued at, or a fifteenth part of every man's personal estate, according to a reasonable valuation. This sum was first reduced to a certainty in the reign of Edward III., and long after, when the value of money had much changed, the amount to be paid by each town or parish as its fifteenth remained as then fixed.

Fifth (Sax. fifth), in Mus, a distance com-

prising four distonic intervals, that is, three tones and a half. It is the second of the consonences in the a half. It is the second of the consonances in the order of their generation. As consecutive fifths de not produce a good effect, they are not allowable in harmony. There are three kinds of fifths; viz., the perfect lifth (C—G), consisting of three whole tones and a semitone; the flat, diminished, or imperfect lifth (H—F), consisting of two whole tones and two semitones; and

the extreme sharp, or superfluous fifth (C—G sharp), composed of four whole tones.

FITTH-MONARHY MEN, fifth, the name of a sect of religious fanatios who appeared in England during the Protectorate of Oliver Cromwell, and whose distinguishing tenet was a belief in the speedy advent of a fifth monarchy (succeeding the four mentioned by Daniel,—the Assyrian, Persian, Grecian, and Roman), of which Christ was to be the head. In 1860, a few mouths after the Restoration, they broke out into a serious insurrection in London, under the leadership of one of the name of Venner, on which occasion many of them loat their lives, and others were afterwards executed. The sect noon afterwards became extinct. Fig. (See Ficus.)

Figaro, fig-a-ro, is a dramatic character, brought by Beaumarchais on the stage at Paris about 1785, in by Destinarchas on the stage at Taxis avoid 1755, in his two dramas, the Barbière de Seville and Mariage de-Figare. Since that time Mozart, Paesicilo, and Ros-sini have made the name celebrated in classic operas; and now the term is frequently used to denote an

adroit and cunning accomplice.

Figure, fig-ger (Fr. figure, Lat. figura), expressive of the form, shape, or distinguishing characteristics of anything as expressed by the outline or terminating extremities. In Arith, the term is applied to certain characters, by which any number which can be expressed by a combination of the nine digits and the cipher is denoted; as, 1, 2, 3, 4, 5, 6, 7, 8, 8, 0. These figures are called Arabio, on account, as it is surmised, of their being introduced into Europe by the Arabiaus. In Theol., the term figure is used to denote a type or symbol. In Geom., it is used in two different senses. symbol. In Geom., it is used in two different senses. In the first instance, it denotes, generally, a space-bounded an all sides, whether by lines or by planes; in the second sense, it signifies the representation (by drawing on paper or otherwise) of the object, or subject of a theorem or problem, in order to render the demonstration or solution to be more easily under-stood and followed: in this last sense, the word figure stood and followed: in this last sense, the word figure is analogous to diugram. All bodies are necessarily inclosed by one or more boundaries, and therefore possess figure; hence, figurability, or the quality of possessing figure, is termed one of the first essentials of matter. In painting, and art generally, figure is applied to the representation of living objects, as a statue or the form of man.

Figure in Rhat is defined to be in a contraction.

FIGURE, in Rhet., is defined to be, in general, "that income which is prompted either by the imagination or by the passions." Rhetoricians commonly divide them into two great classes,—figures of words and figures of thought; the words in the former case being employed in a sense different from their original and primitive meaning; in the latter the words are used in their proper and literal meaning, the figure consisting in the turn of thought; but the distinction is of no great use. One is apt to imagine, that as figures of speech always denote some departure from sim-plicity of expression, they are therefore artificial, are-of late growth. This, however, is by no means the case; for the earliest and least cultivated languages are generally those that abound most in figures. the very pancity of his language, and the want of proper expressions to convey his meaning, man, in his untutored state, is led to exercise his fancy, and express his ideas in image and metaphor. Hence, then, what is a necessity in the language of the savages is that which also gives beauty and grace to the polished languages of civilized life. Figures serve to enrich a language and render it more copious; and they also bestow a dignity upon style, by enabling us to avoid. the frequent use of common expressions to which the ear has been accustomed. More particularly, figures give us the pleasure of enjoying two objects presented together to our view without confusion,—the one signified by the figurative sense, which may be termed the principal object, and the one signified by the pro-

#### Figure-head

per sense, which may be termed accessory; the principal making a part of the thought, the accessory being merely ornamental. Lastly, figures possess a signal power of aggrandizing an object, giving frequently a much clearer and more striking view of the principal object than could have been the case if it had been expressed in simple terms and divested of its accessors idea.

sory ides.

RIGURE-HEAD, an ornamental figure or bast, emblematical of war, navigation, or commerce, &c., fixed on the top of the projecting portion of a ship's stem or

FIGURE OF THE EARTH. (See EARTH, GEODESY.)
FILARIA, fe-lai-re-ā (last. filum, a thread), a gen. of
parasitic entozos, common to large and small animals,
and infesting even certain of the mollusca. Of this family the most inimical to the comfort of man is the Guinea-worm (Filaria medinensis), which, in hot climates, insinuates itself under the skin of the lower members, causing excruciating pain. It has a slender and thread-like body, and sometimes attains a length of six feet. It is met only in certain portions of the torrid and temperate zones in Africa and Asia, and is

especially frequent on the African coast.

FILBERT. (See CONTLUS.)

FILB. 7ile (Sar. Feel), an implement used in many trades to produce a smooth surface on hard substances, as metals, ivory, or wood, &c. They are made of bars of steel rendered doubly hard by a process called *double* conversion, drawn the required size at the tilt-hammer, conversion, drawn the required size at the tilt-hammer, and then shaped, the square and flat ones by the hammer and common anvil only, but those of round, half-round, and three-angled forms, by means of bosses or dies made in the above shapes, which fit into a groove left for them in the anvil. The steel blanks having been thus formed, are next annealed, or softened, to render them capable of being cut, by placing a number of them together in a brick oven rendered air-tight by filling nu all the interstices with placing a number of them together in a brick oven rendered air-tight by filling up all the interstices with sand (to prevent oxidation of the steel, to which it is very liable if the air be admitted), and then making a fire play as equally as possible all round until they are red hot, when the heat is discontinued and the steel allowed to cool gradually before it is uncovered. The surface to contain the teeth is now rendered as smooth as possible by grinding or filing; the teeth are then cut with a carefully ground chisel, each incision being made separately. The next and last process,—that of made separately. The next and last process,—that of hardening, is performed in various ways by different makers; the ordinary method, however, is to cover the files with a kind of composition or protecting varnish, to prevent oridation and scalding of the steel when heated; they are then heated uniformly throughout, and lastly are plunged in cold fresh water to cool them as quickly as possible. A great number of extremely ingenious machines have been invented at various times to facilitate the process of file-making, but they have all proved more or less defective; however, notwithstanding this, it is very probable that many of the commoner kinds are out by machinery. Film (Lat. Alum, a thread), in Mil., the term applied to two soldiers standing one before the other,

or conjointly to any soldier in the front rank and the man who stands immediately behind him in the rear rank, when the company or regiment is drawn up in line. A body of soldiers is often spoken of as consisting of so many rank-and-file, which includes the corporals, lance-corporals, and privates, who stand in the ranks, the officers and sergeants having different posts ranks, the others and expense aring interest possessioned to them in front, on the flanks, or in the rear of the company, as occasion requires; thus, a company of 80 men, exclusive of officers and sergeants, would be spoken of as consisting of 80 rank-and-file, or 40 files.

FILE-MARCHING, in Mil., when a company is drawn up in line, and the order is given to face to the right or left and march in that direction. This method of marching is called file-marching. man and his rear rank man on his right or left, according to the direction in which the company has faced atill composes a file. (See File.) File-marching is a difficult movement for recruits, unless the leading file marches steadily, and takes the proper length of pace, and each file behind takes can to "look up," or keep closely in the rear of the file immediately before it, and those of others are mucilsginous. The rhisomes Men may be taught, the necessity of doing this when of marching is called file-marching. Each front rank man and his rear rank man on his right or left, accord-

### **Filices**

marching in file, by frequently viving the order "Front turn," and immediately halting the company, when the loss of distance between some of the files will become apparent. Men marching singly in a line, one after another, are said to be marching in single or Indian

FILIBUSTERS, fil-le-bus'-ters, is the name given to certain adventurers in America, and is derived from the French filbustiers, a corruption of the English freebooters or buccaneers. (See Buccaneers.) The filibusters have come into notice since the termination of the late war between the United States and Mexico, and exerted themselves with setting on foot, within the United States, military expeditions designed to operate in the Spanish-American countries to the south. The pretended object of these expeditions was the emancipation of those countries from tyranny, foreign or domestic, and the introduction of democratic institutions after the model of the United States; but their real object undoubtedly was their own aggrandizement, by re-enacting the part of the original Spanish con-querors. Though the setting on foot of such expedi-tions is contrary to the laws of the United States, jet, as they enjoyed a considerable degree of popular favour, no strenuous legal measures were adopted against them. The most noted expedition of this sort against them. The most noted expedition of this sort was that led by William Walker against Nicaragus in 1855, who succeeded in maintaining himself in that country for nearly two years; but was at length expelled by the union against him of the other Central American states. Walker was subsequently taken and shot at Truxillo, in Central America, in 1860, when engaged on another piratical expedition. ing is also a cant term much used of late years in the legislative assemblies of the United States to designate the employment of parliamentary taotics to defeat a measure, by raising frivolous questions of order, calls to the house, motions to adjourn, &c., in order to weary out the opposite party and to gain time.

Filices, file-seez, in Bot., the Fern fam., a nat. ord. of Acotyledones, sub-class Acrogenæ, consisting of

herbs with rhizomatous stems, and of arborescent pla The leaves, or fronds, as they are generally called, arise irregularly from the rhizome, or are placed in tufts upon the aper of the stem; they are almost always circinate in vernation, and are simple or compound. The fructification consists of little somewhat rounded cases inclosing spores. These cases are called sporangia, and are collected in heaps, usually on the under surface or at the margin of the fronds, or rarely on the upper surface, or occasionally in a spiked manner upon a simple or branched ruchis. The order rarely on the upper surface, or occasionally in a spiked manner upon a simple or branched rachis. The order is commonly divided into three sub-orders; namely, Polypodiece, Dancee. and Ophioglosece. Ferns are found in greater or less abundance in every part of the globe. In the northern hemisphere, they are herbaceous plants, but in the southern hemisphere, and in the tropics, they are sometimes arborescent, having stems occasionally fifty feet or more in height, and with the general habit of palms. There are about 210 genera and upwards of 2,000 species. Ferns are much cultivated in greenhouses

cultivated in greenhouses and closed glass cases (see WARDIAN CASE), and their graceful and tender green fronds now adorn thousands of English homes. The annexed[jllustration represents species of the two genera most commonly culti-vated; a being the Scolopendrium vulgare, or hart's tongue, and b a species of Polypodium, or polypody. Several ferns have farinsceous rhizomes or stems,

## Filigree

possess well-marked unthelmintic properties. The silky hairs found on the rhizomes and stalks of some species have been used for stuffing cushions and as mechanical styptics.

FILIGRER, OF FILLAGREE, fill-e-gre, fill-lit-gre FILIGERE, or FILLAGERE, Mu-spre, Mi-li-re (Lat. films, a thread, and graums, a grain), a delicate species of ornamental work in gold or allyer, wrought in little threads of the metal intertwisted in excentric forms and patterns. It is of eastern origin, and was first introduced into Europe by the Italians. In the East, India, Sumatra, and Java have been celebrated for the high excellence to which they have arrived in the prosecution of this art. When the gold or silver has arrived at a molten state, it is drawn into wire on an anyl, and then twisted. After twisting, it is hammered down again into a flat state, and formed into the shape of flowers and leaves. When the flignee is finished, it is cleaned by boiling in arrived in the prosecution of this art. When the gold water with common salt and alum, or occasionally limejuice. The Chinese often manufacture filigree jewelry, but which is not so elegant as that produced by the Malays. Filigree-work has an extensive sale on board the Peninsular and Oriental Steam-packet Company's vessels at Ceylon, where it is eagerly sought after by

vessels at Ceylon, where it is eagerly sought after by the European passengers.

FILLIBEC. (See KILT.)

FILLER, Mi-let (Lat. Mum, a thread), in Arch., the name given to a nurrow band, or flat ribbon-moulding, frequently used to divide mouldings of a curved form. It is a common feature in architectural designs, especially in entablatures. It is distinguished from the hand by being of narrow width and always flat. (See BAND.)

FILLY, fil'-le (Ang.-Nor.), a name applied to a young mare before it has reached its third year. For further information see article HORSE.

FILTER, fil'-ter (Fr. filtre), an apparatus by which fluids are separated from any solid matter held in suspension. They may be divided into four classes: those pension. They may be divided into four classes: those used in straining chemical liquids; those used for purifying water for household uses; those employed on a large scale by water-companies; and those used on shiphoard for changing salt water into fresh. Chemical filters are either used for rendering fluids transparent, or for the purpose of separating and washmical litters are either used for rendering fluids transparent, or for the purpose of separating and washing precipitates. They are usually made of unsized or blotting paper. (See Filtratrox.) Household filters for purifying water, either for drinking or culinary parposes, are made in various forms. In Paris, a large quantity of the river water is purified by passing it through boxes, at the bottom of which is a layer of charcoal between two layers of sand. Filtered river water, atthough not so agreeable to drink as spring water, is still well suited for other purposes. When water is filtered on a large scale by water-companies, the process is usually accomplished by means of filtering-beds. (See Waterworks.) The conversion of salt water into fresh is very important, and depends mainly upon distillation. There are many forms of apparatus for this purpose, and they are of great service on board ship, where the absence of fresh water often causes great misery. Dr. Normandy's method of converting salt water into fresh is largely adopted by the Admiralty and the large steamboat companies.

verting salt water into fresh is largely suppose by an Admiralty and the large steamboat companies.

FILTRATION, fl.trat.shun, in Chem., the separation of a liquid from any solid matter contained in it. It is generally effected by means of a filter formed of the corner of a round or square piece of filtering paper, shaded into four and placed on a funnel. When the folded into four and placed on a funnel. When the liquid to be filtered is corrosive, sand, powdered glass,

liquid to be flitered is corrosive, sand, powdered glass, or wisps of sabestos, are generally used. A piece of cotton wood, loosely plagged into the neck of a funnel, forms a very good extempore filter for ordinary purposes, and may be applied to culinary as well as to themical operations.

Fin, fin (Bax, fins), in Ichth., a flat expanded organ, projecting from the bodies of flahes, and used as an instrument of locomotion in the water. The fins of fishes are supported by elongated filsmentary bones or rays, by the number and nature of which the naturalist is able to distinguish the various groups. Many species of the whale tribe possess an immovable fin upon the back, composed merely of a reflexion of integument is anic to distinguish the same structure, but is derived. The great works of art now extant may be supposed to painting, soulpture, back, composed merely of a reflexion of integument engineering, and architecture, all of which appeal to over a mass of dense and ligamentous cellular mem—the eye, as the medium and interpreter of the pleasure brane. The tail in has the same structure, but is derived. The great works of art now extant may 040

#### Fine Arts

moved by the action of muscles upon the caudal vertebree, which are continued through the middle part. In works in ichthyology, a system of notation, founded upon the number of fin-rays, is employed. founded upon the number of fin-rays, is employed. Thus the number of fin-rays in the perch is expressed in the following manner:—D. 15, 1+13; P. 14; V. 1+5; A. 2+8; C. 17. This denotes that D., the dorsal fin, has in the first fin 15 rays, all spinous or bony; in the second fin, 1 spinous and 13 soft; P., the pectoral fin, has 14, all soft; V., the ventral fin, has 1 spinous and 5 soft; and C., the oaudal fin, 17 rays.

Finall, fin-a-le (Lat. finalis), the last portion of any act of an opera, or part of a concert. Finales are of different kinds. In instrumental music, they are commonly of a lively character and performance, combined with a quick movement; while in operas, they generally consist of a series of compositions for many voices, and are various in character, time, and move-

voices, and are various in character, time, and movement.

FINANCE, fe-nans' (Fr.), in Polit. Econ., is employed to denote the revenues of a king or state. (See Taxa-

TION, REVENUE, CUSTOMS, EXCISE, &c.) FINCHES, fin'-takes (SEX. finc), a fam. of birds belonging to the ord. Passeres, and the dir. Controstres, and known by the general name of finckes. According to known by the general name of finckes. According to Mr. Vigors, this family embraces, in addition the Alaudina, or larks, to which the buntings, or Embericina, seem nearly allied, the greater part of the Linnman Fringillida, with the Linnman Tanagrina (tanagers), which approach these in their external characters and in their habits. As far as has bitherto been ascertuined, none of the tinches are of large size, and in their habits and general appearance there is a strong likeness. For the most part they are hardy birds. Their food chiefly the most part they are hardy birds. Their food chiefly consists of grain, worms, and insects. The characteristics of this family of birds are,—beak straight, longer than deep, conic and pointed; mandibles nearly equal, cutting adges entire, forming a straight commissure; nostrils basal, lateral, oval, partly hidden by the frontal plumes; wings with the first quill-feather longer than the fifth, but a little shorter than the second or third, which are equal, and the longest in the wing; legs with the tarsi of moderate length; toes divided, and adapted for hopping and perching; claws curved and abarb.

FINDER OF GOODS, find or (Sax. findan, to find).—
The law on this subject is, that the finder of goods is to use all due means to discover the rightful owner; and if he keep and appropriate the articles to his own use, knowing the rightful owner, or without having made due exertion to find him out, he is held guilty of larceny. Fading the rightful owner, the goods become the property of him who finds them.

First, fine, in Law, is a pecuniary mulct or punishment imposed by a competent jurisdiction, and was so called because it was said finem facere de transgression.—to make an end of the transgression. The statute law has seldom determined the amount of fines to be inflicted for particular offences, and the common law never. They vary according to the aggravation or otherwise of the offence, the quality and condition of the parties, and numerous other circumstances. This the parties, and numerous other circumstances. This power, however, which is in the hands of the court, is far from being wholly arbitrary; for the Bill of Rights has particularly declared that excessive fines ought not to be imposed, nor cruel and unusual punishments inflicted; and the Magua Charta determines that no man shall have a larger smercement imposed upon him than his circumstances or personal estate will bear; saving to the landholder his contentment, or land; to the trader his merchandias, and to the country man. the trader his merchandise; and to the countryman his wainage, or toam and implements of husbandry. Hence it is never usual to inflict a larger fine than a man is able to pay without touching the implements of his livelihood; but instead thereof to inflict corporal

punishment or a limited imprisonment.

Five Aurs.—This term may be viewed as embracing all works which are executed by the mind and ingenuity of man. The phrase has of late, however, been restricted to a narrower and more technical significa-

## Fine of Lands

really be looked upon as models in their various lights of perfection, and they are chiefly composed of the relics of the ancient masters and classic art, consistrelice of the ancient missters and classic art, coesisting chiefly, as they do, of sculpture, the pictures of the old Italian school, the German, Dutch, and Flemish masters, and, it may be added, the works of Hogarth and Reynolds; all of which may be looked upon as different types of high art excellence. The schools of art which, in the present day, elevate the taste of the public, cannot be said to number more than three,—the English the Franch, and the latter lish, the French, and the German; and the latter, perhaps, for pre-eminence in correct and classic drawing, ought to bear away the palm. The school of Germany is not older than the present century, and yet, in purity and elevation of style, it holds a rank far auperior to that of France. This, perhaps, is owing to the fact of its being strictly guided by the old Italian rules of art in light and shade. This pre-eminence of Germany is not generally admitted, of course, by either the English or French schools; but there is no doubt as to the fact, and some of the best pictures of the French artist Ary Scheffer may be said to owe their excellence to the German schooling which that artist underwent. With regard to fine arts generally, England bears away the palm, as her excellence in painting (apart from classic rules), engraving, and architecture, can hardly be rivalled by other nations, although in the latter arranch she may be perhaps, a lish, the French, and the German; and the latter, architecture, can nardy be rivaled by other nations, although in the latter dranch ale may be, perhaps, a little weak. To sum up these remarks. The purity of design of the German school, and the variety and dexterity displayed in that of France, are qualities which the artists of this country would never like to deny; while, on the other hand, the Germans and French give praise to, and condescend to copy, the brilliant colouring and truth to nature which is always displayed by the English artists. To conclude in the displayed by the English artists. To conclude in the elegant language of Brando's Dictionary, "the fine arts are the offspring of genius,—their model na-ture, and their master tasto. Characterized by simplicity, they should never wander into luxury, nor degenerate into extravagance." (See Exhibitions, AŭT.)

Fine of Lands, in Law, is a name given to certain judicial proceedings which were formerly in common use in the conveyance of lands and hereditaments, but which have been abolished by 3 & 4 Will. IV. c. 73. Questions, however, regarding them will still occur, and the subject is thus one of present interest. It is defined to be "an amicable composition or agreement of a suit, either actual or fictitious, by leave of the king or his justices, whereby the lands in question became or were acknowledged to be the right of one of the parties." The party to whom the land was to be conor were acknowledged to be the right of one or one parties." The party to whom the land was to be conveyed or assured commenced an action or suit at law against the other, by suing out a writ of practice, called a writ of covenant, founded upon the breach of a supposed agreement or covenant that the one should convey the lands to the other. On this writ there was due to the lands to the other. posed agreement or covenant that the one should convey the lands to the other. On this writ there was due to the king, by ancient prerogative, a primer fine, amounting to about one-tenth of the annual value of the land. The suit being thus commenced, there followed the licentia concordand, or leave to compromise the suit, for which there was another fine due to the king, called the king's silver, or sometimes the post fine, equal to about three-twentieths of the annual value of the land. Then came the concord, or agreement itself, after leave obtained from the court, which was usually an acknowledgment from the deforciants (or those who kept the other out of possession) that the lands in question were the right of the complainant. From this acknowledgment, or recognition of right, the party levying the fine was called the cognizer, and he to whom it was levied the cognizer. The acknowledgment had to be made either openly in the court of Common Pleas, or before the lord chief justice of that court, or else before one of the judges of that court, or two or more commissioners in the country, empowered by a special authority, all of whom were bound, by stat. 18 Edward I. st. 4, to take care that the cognizors were of full age, sound memory, and out of the party levying the fine was called the cognizor, and he to whom it was levied the cognizor. The acknow-ledgment had to be made either openly in the court of Common Pleas, or before the lord chief justice of that court, or else before one of the judges of that court, or else before one of the judges of that court, or two or more commissioners in the country, empowered by a special authority, all of whom were bound, by stat. 18 Edward I, st. 4, to take care that the conjustors were of full age, sound memory, and out of prison. If there was a married woman among the cognizors, she was privately examined whether she captions, she was privately examined whether she captions, she was privately examined whether she that of substanties, while the comparative ends in sold freely and willingly, or by compulsion of her husband. By these acts all the essential parts of a fine genders, the seems being indicated either by distinct words or by epithets. The verbs have only two simple

## Finnish Language and Literature

of the writ of covenant and the concord, naming the parties, the parcels of land, and the agreement, and which had to be enrolled in the proper office. The foot of the fine, or conclusion of it, included the whole matter, reciting the parties, day, year, and place, and before whom it was acknowledged or levied. In order that the fine might have full effect, it required to be openly read and proclaimed in court. This mode of conveyance was so effective that it bound not only conveyance was so effective that it bound not only those who were parties to the fine, but all other persons whatsoever, unless they brought their action or sons whatsoever, unless they brought their action or made lawful entry within five years after proclamation made, except in the case of married women, infants, prisoners, persons beyond the seas, and such as were not of whole mind, to whom, or their heirs, five years were allowed after they recovered their legal powers.

FINGER-BOARD, fix'-ger-bord (Ang.-Sax.).—The whole of the keys, both black and white, of a pisnoforte or organ, are so called. That thin black board which extends over the necks of instruments of the violin hind on which during performance the atrings are

kind, on which, during performance, the strings are pressed by the fingers of the left hand, is also deno-

minated by this term.

FINGREING, fin'-ger-ing (Ang.-Sax.), the art of so disposing the fingers on any musical instrument, more especially on the pianoforte and organ, as to produce the required notes in an easy and graceful manner. A good method of fingering is of the utmost importance to the student, as without it the easiest passages will often appear difficult, and the difficult ones almost impracticable.

impracticable.

Finial, fin's-all (Lat. finis, end, termination), in Goth. Arch, the term by which the carred ornament which surmounts the top of pinnacles, canopies, mouldings, &c., is designated. It is generally in the form of foliage clustering round a knob or boss. The ornament called a poppy-head, frequently used to finish the upright sides of open pews in churches, is a finial.

Finings, fi-nings (Fr. raffiner, to purify), a term applied to those substances which are used for clarify-

ing or clearing, in brewing and other manufacturing operations. Some of these are made by the persons using them, and others are purchased by them from the manufacturers. Isinglass is made into finings by manuscurers. Isingless is made into finings by mixing it with beer or cider, which is then stirred till the isingless dissolves, when the mixture is strained through a sieve; it is then mixed with some of thesame beverage as that which is to be fined, until it is brought to a liquid state. Finings of this kind are much used by browners. A sieve and the liquid state is the liquid state. brewers. A mixture of alum with carbonate of

by brewers. A mixture of aium with earbonate of sods, or salts of tartar, dissolved in hot water, forms a fining much used by distillers and rectiflers.

FIFITE, fi-nite (Lat. finis, end), signifies having a limit, bounded. It is the opposite of infinite.

FINNISH LANGUAGE AND LITERATURE, fin-nich.—The language of Finland forms one of the chief branches of the Uralo-Altaic family, being, with the Esthonic and Lappish collaterals, kindred to the languages of the Urriane on Eastern Turks Ormani Turks Semoyalt. and Lappish collaterals, kindred to the languages of the Ugrians, or Kastern Turks, Osmanli Turks, Samoyeds, and other Tartars, Magyars, Mongols, and Tunguses, whose chief branch are the Mantchoos. All these constitute the so-called Scythic, or Turanian, or Allophylic family. The Finnish comprises a number of dialects, of which the principal are the lower, which is used along the coasts, its Abo variety being that which is used in books; and the upper, which is spoken in the inland regions, divided into the sub-dislects of Ulea and Viborg. It is written by Latin or German characters; but the letters b, c, d, f, g, occur only in a few foreign words, and g is now obsolete. It is, however, rich in vowel-sounds, having no fewer than eight, d and ö standing at the end of the alphabet. It has also many diphthongs, and, according to Rask, it is

#### Finnish Language and Literature

tenses,—the present and the past, the others being periphrastic. Their conjugation is complicated, their voices, moods, and other nice shades of meaning, being expressed by cartain syllables inserted between neing expressed by certain symmes inserted setween the root and the personal suffixes. There are no separate particles, and all their prepositions are placed at the end of the words to which they are re-lated. From the number of syllables thus brought lated. From the number of syllables thus brought together, some of the words are of great length (from eight to ten, and sometimes even as many as eighteen syllables); but in this way the most complicated ideas may often be expressed in one word, which would require several in most other languages. The construction is extremely free, without endangering the clearness of the sense. There can be little doubt, from the character and construction of the language, that this character and construction of the language, that this is not only one of the most ancient but one of the purest of the whole Asiatic-European family, being less mixed with foreign elements than the Hungarian, Turkish, or Mongolian. The literature of Finland is Turkish, or Mongolian. The intersture of Finland is particularly rich in popular songs or renses, which are sung by the runolainen, or song-men, to the sound of the favourite national instrument, the keatele, a species of harp with five wire strings. They may be divided into mythical and lyrical songs. These songs were handed down by oral tradition from generation to were handed down by oral fradition from generation to generation for many centuries, until at length, about the close of the 18th century, Professor Porthan, the Bishop Persy of Finland, made a collection of them, which was published at Abo. With the death of Porthan the subject went to sleep, until Dr. Topelins entered upon the same field, and published five volumes of ancient and modern popular songs, the last of which appeared in 1831, at Helsingfors. Topelins prepared the way for Dr. Rlias Lönnrot, the most enthusiastic and successful of all the collectors most enthusiastic and successful of all the collectors of old Finnish poetry. He was fortunate enough, in 1832 and the following year, to discover among the peasants of Karelen, and still farther on in Russia, a series of valuable poems, preserved by tradition, and comprising a mythical epic on the subject of the Finlandic Orpheus, the God of Song, Weinemöinen, his journeyings and adventures. He endeavoured, as far as possible, to present this eyele of songs in a connected of the present this eyele of songs in a connected of the connec epic form, and published them under the name of "Kilevala" (from Käleva, the great ancestor of all Finnish herces), at Helsingfors, in 1835. Alexander von Hum. bolds, in his Cosmos, in speaking of this work, says:
"Among the Finnish tribes who have settled far to the
west in the lowlands of Europe, Elias Lönnrot has
collected from the lips of the Karelians, and the country people of Olonets, a large number of Finnish songs, in which 'there breathes,' according to an expression of Jacob Grimm, 'an animated love of nature, rarely to be met with in any poetry but that of India An ancient egos, containing nearly three thousand verses, treats of a fight between the Fins and Laps, and the fate of a demigod named Vaino. It gives an interesting account of Finnish country life, especially in that portion of the work where Ilmarine, the wife of the smith, sends her flocks into the woods, and offers up prayers for their safety. Few races exhibit greater more remarkable differences in mental cultivation, and in the direction of their feelings, according as they e been determined by the degeneration of servitude have been determined by the degeneration of servitude, warlike fenocity, or a continual striving for political freedom, then the Fins, who have been so variously subdivided, although retaining kindred languages. In 1834, the Findlandie Society of Literature was established at Helsingfore, and has done much to spread a kinowledge of, and develop a taste for, this language. In 1841, it sent out Dr. Löunrot to travel. ahroughout the country, in order to collect ancient songs, and he was again very successful. The result of his labours he published the same year, under the name of Kantelstar, or Songs for the Harp, in three name of Kantelstar, or Songs for the Harp, in three volumes, containing no fewer than 652 ancient popular songs. In 1842, he published a collection of about 2,000 charades. In 1854, Radbäk published a collection of Finnish legends and tales. These published have given a great simulus to the study of the Finnish language; and while the upper classes still sling to the use of the Swedish, the peasantry welcome with avaidity every addition to the limited stock of their 842

# Fire-Brigade

printed literature. Newspapers and periodicals in their native tongue now circulate among them, and are eagerly read. The number of newspapers and periodicals published in Finland in 1858 was eighteen, of which cals published in Finland in 1858 was eighteen, of which eight were in Finnish and ten in Swedish. An interesting and valuable work is published annually, under the title of "Onr Country's Album;" and, though written in Swedish, contains translations of oppular songs, legends, sagus, &c., together with literary, philologic, and authetic papers, all bearing mpon the language, poetry, and history of Finland. The proces literature of the people is devoted almost exclusively to religious and moral subjects. A Finnish translation of the New Tastament anneared in 1548 translation of the New Testament appeared in 1548, and a portion of the Old Testament in 1552; but the whole Bible was not translated into Finnish till 1642. whole Bible was not translated into Finnish till 1642. The greatest living poet of Finland, and, indeed, the greatest among all that that country, in modern times, has produced, is Euneberg, who, though he writes in the Swedish language, is truly national and patriotic in spirit, and the genius of his country is the only muse that he acknowledges. The best grammar of the language is that of Jacob Juden, in Swedish (Viberg, 1818), and the best dictionary that of Lönarot, Helmington 1822. singfors, 1853.

Bingiors, 1893.

Fiord, or Fiord (fe'-ord), the Norwegian and Danish name applied to any bay, creek, or arm of the sea which extends inland. It is somewhat analogous to the Celtic long or lock.

Firs, fire (Sax. fyr), heat and light emanating visibly, perceptibly, and simultaneously, from any body. The terrific energy of fire, the most important agent of civilization, the similarity of its effects with that of the sun, its intimate connection with light, its terrible and yet genial power, and the beauty of its changeful fiame, easily account for the reverence in which it was held in easily account for the reverence in which it was not in ancient times. At a period when cause and effect, form and essence, were not distinctly separated, fire became an object of religious veneration, a distinguished element in mythology, an expressive symbol in poetry, and an important agent in the systems of cosmogony. It gained a place among the elements, and for a long time was believed to be a constituent part in the composition of all bodies, and to require only the concurrence of favourable circumstances to develop its activity. At a later period, fire, under the name of phlogiston, was considered to be the source of all chemical action. At the present day, the phenomena which were formerly ascribed to fire are attributed to the affects of heat.

the effects of heat. (See COMBUSTION, HEAT.)

FIRE AND SWORD, LETTERS OF, in the early law of
Scotland, were letters granted by the Scotch privy counoil against any one who refused to obey the decrees of a court, and were principally employed to disloge refractory tenants who refused to give up possession as re-quired by order of the judge. These letters authorized the sheriff to call for the assistance of the county, and dispossess him by all methods of force. The practice uspossess mu by an memous of force. The practice now is, where one opposes by violence the execution of a decree or any lawful diligence, which the civil magistrate is not able by himself or his officers to make good, to make application to the military for assistance, who enforce the execution manu military.

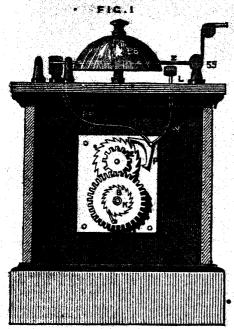

Fire-Annihilator. (See Annihilator, Fire.) Fire-Arms. (See Arms, Abrillery, &c.) Fire-dalls. (See Mutrors.)

(See Muthors.) FIRE-BALLE. (See DARROLE.)

FIRE AND BURGLAR ALARUM.—The fact that losses of both life and property from fire have of late been on the increase, serves to draw special attention to any practical contrivance for mitigating the evil by giving timely notice of any outbreak. Of such a nature is the self-acting fire-alarum and thief-detector which has been invented and patented by Mr. W. Gilbert, of Enfield. The apparatus is very simple in construction; it is self-acting, and does not involve the presence of an electric battery or other extraneous agent to insure its correct working. The invention refers to a peculiar application of a fusible wire or cord connected with the several rooms of a house, parts of a ship, or other place, and attached to an alarum in such a manner as piace, and attached to an alarma in such a maner as that, when acted upon by heat, it will be dissolved or melted, by which the train of wheels connected with the hammer and bell is liberated, and the alarm given. The following is one way in which the fusible wire or cord is prepared:—When a material is required,

## Fire and Burglar Alayum

capable of being fused at a low temperature, the proportions are—gutta-percha 18 parts, chloride of sulphur 2 parts, sulphures of antimony 8 parts, and copper bronne. I part, dissolved in chlorotom, naphtha, oil of tarpentine, or other solvent by gentle heat, afterwages submitted to a temperature of from 250° to 300° Fahr, for from two to seven hours, in a closed wessel, which compound will melt at from 96° to 120° Fahr, according to the tem-

F1C.2

THE AND BURGLES ALARUM.

men was placed under the command of a superintendent, each company paying so much towards the support of the whole. Mr. Braidwood, at that time the director of the fire-engines of Edinburgh, was invited to take the command of this new force, possiplate of lead 2 parts, esteined magnesis from 2 to 5 parts, gutta-percha 10 parts, escoutchood 10 parts, suphases of autmony 2 parts, and chloride of support of the strength of the protectives from fire depositions will fuse at from 130° to 200° Fahr., and is a conductor of feet, and not highle to be affected by moisture, gases, or time. It is made into the form of a cord or vives by passing it between the form of a cord or vives by passing it between the form of a cord or vives by passing it between the form of a cord or vives by passing it between the form of a cord or vives by passing it between the form of a cord or vives by passing it between the form of a cord or vives by passing it between the form of a cord or vives by passing it between the form of a cord or vives by passing it between the form of a cord or vives by passing it between the form of a cord or vives by passing it between the form of a cord or vives by passing it between the form of a cord or vives by passing it between of the Linuidos Fire-brigade. The force of this latter consisted of between 30 and 40 large engines capable of throwing 88° gallons a minute to a height of from 885.

# Fire-Brigade

2 parts, bin 2 parts, and affirmary 1 part, melted together, is used. This will fuse at from 215° to 500° Pahr., by the omission of the mercury and bismuth. Fahr, by the omission of the mercury and binmath, more or less. In the accompanying engraving, fig. 1 is a front elevation of the apparatus, and fig. 2 is a plain or top riew. A (fig. 1) is an outer wood case placed in front, inclosing the alaram movement. At the centre of the apparatus two plates contain be-tween each other a pin (B), on which is attached a

ween each other a pin (B), on which is attached a spring, which is the prime mover of the wheel-gear, on which is fixed a ratchet-wheel (E), to enable the spring to be wound up similar to a chock spring, and a toothed wheel (S) having thirty-two divisions, which drives a parion, whose spindle passes through both holding-pastes, and carries the escapement-wheel (E) containing twenty-six divisions. P is a palate which regulates the motion of the escapement-wheel E, the introduces an excitation of which produces an excitation produce. the escapement-wheel E, the introvement of which produces an oscillating motion, which communicates movement to the wire W, furnished with a hammer, L. When the machine is in motion, the hammer L plays on the bell B. A wire (P) is fixed on the same spindle as the wire W at P, by which the hammer is held at rest by the lever H, which is held in a position to prevent the motion of the wire P, by a fusible wire or cord (Z) attached to the end of the lever H at a. The fusible wire or cord (Z) passes through the puller E where it is the end of the lever H as a. The lassible wire or cord (Z) passes through the pulley S, where it is carried forward through a unusber of rooms or spartments, being fixed in the same way as bell-wires are usually fixed, a constant strain being maintained on the fusible wire or cord by a string attached to the lever H at N; so that should the fusible wire or cord Z be acted upon by heat sufficient to melt it, a separation will take place and liberate the lever H, and the spring N will move it back as indicated at e.e. so as to allow the wire P P to oscillate, and the hammer L to play on the bell B until the spring is spant. By a simple arrangement, the apparatus is connected with doors or windows; and thus not only an outbreak of fire, but also any attempt at foreible entry, is at once indicated.—Ref. Mechanic's Mag., vol. iiv., New Series.

First-Bergars, an institution of men and fire-engines, fire-escapes, and so forth, under the com-mand of assperimendent, and supported principally by the fire insurance offices in London and else-where, for the purpose of being in a constant state of readings to warms. where, for the purpose of being in a constant state of readiness to preserve property and life from destruction by fire. This was the plan of organization until, in consequence of the London Firshrigade Bill, which come into operation on the lat of January, 1866, the brigade passed into the management of the Metropolitan Board of Works. Until the year 1825, all the fire insurance companies of London had distinct and separate establishments of fire-engines, &c.; but in that year the Union, the Sun, the Royal Exchange, the Atias, and the Phoniz companies joined their establishments of fire-engines together, and formed one association of fire-brigade. This association lested association or fire brigade. This association lasted until the year 1838, when it was found that it was not sufficient to conquer the devastating element which was constantly making raids on London. It was therefore determined, in 1833, to incorporate all the detached forces of engines belonging to the remaining fire-offices which had not joined the association; and this complete band of argines and men was placed under the command of a superin-

by hand, and on In the year 1961 tended to several other streets and war contests, and continued froming for these says. The famous far. Breshwood, the intended superintends of the London Fern-breught subdishment, but his life by the falling of stine at the buildings, and the loss of property by this filestnesses occurrence was estimated at more this one million and a half of money. This is considered as the most serious fire since the Great Free of 1896, and Mr. Towns states in his work on "Fires and Fire-again." that the cost to the insurance sompanies for extra isbour in assisting to featurable progress of the flames amounted to 41,100. Besides fire-angular, all the offices are supplied with fire-assapes, ladders, and all norts of spare gear. On the ularm of free, by sjudicious code of rules, which the late fire Braidwood framed, each man knows the part he has to perform, and in about five minutes the generality of angines one be got ready and are tearing off to the scane of action. The complement of men to each engine is one angineer, four firement, and a driver; but these are generally increased in number. (See First-Braines.) The Kirs-brigade Bill of 1966 empowered the associated functureur offices to turn over their establishment to the Metropolitan Board of Works. The new system was to be maintained by a restriction of 210,000 ner anum from the governdriver; but these are senerally increased in anuber. (See Firs. Engars.) The Firs-brigade Bill of 1866 empowered the associated fusurance offices to turn over their establishment to the Mctopolitan Board of Works. The new system was to be maintained by a contribution of \$10,000 per assum from the government, a tax on the ratepayers of the metropolis, and a contribution from the insurance offices. It was also established under this act that the force of firemen should be under the command of an officer, to be called the whief officer of the metropolitan Firebrighde. The chief officer at the present time (Oct. 20, 1871) is Captain Eyre Massey Shaw, whose headquarters are in Washing Street. The whole of London is divided into four large districts, distinguished by the latters A, B, D, and D. The A district includes engine-catablishments in Westminster, Brompton, Fullam, Ecusington, St. John's Wood, Hampstand, Baker Street, Regent Street, and Highgate. In the B district fire-brigade establishments are formed in Farringdon Street, Edington, St. Lucks, Wathing Street, Chandes Street, E. Giler's, Holborn, and St. Pancras. The third, or C district, has firshinged establishments in Wellolous Square, Bethna Green, Heeliney, South Hackney, Stoke Newington, Mas End. Row, Retailff, Bishopagate, Shoreditch, De Beatroin Town, and Whitechapel. In the fourth, or D district, fire-brigade establishments in Wellouse Square, Bethna Green, Heeliney, South Hackney, Stoke Newington, Wandsworth, and Waterloo. The whole of this latter force is distributed on the scripts of the fourth, or D district, fire-brigade men stablishment in the Captar of the Part of the Street Rose, the day of the France In addition to the above district states that, taking waterly Review on this subject states that, taking waterly Review on the sure Thames at Millbank, of Southeast Review of Captain Shaw. That good effects have followed the establishment of the London Firebrights arm with the part of the propen years from Lee and the state of the subject of the

whole plant of the Royal Society for Protection of Life from Fire. In the same wear also a salvage corps, also makes the dissection of the Metacopolitan Roard of Torke, was reasonal. The England Science. A recent writer in the Paul Pleasant Science. A recent writer in the Paul Pleasant Science. The present Metropolitan Rise brigade had it, origin in 1833, by the union of ten insurance companies, emplanting the lengthcome spanish squirt', and the baselite obtained were so manifest, that before Blife the number of dre-offices subminising the Brigade and reached a total of thirty. In 1866 the Board of Works took over the plant and countral of the establishment; the offices giving up their apparatus and admignation grantificately, and also agreeding to pay, ander the new set, 256 annually upon every million of their manuscess. It is this reconstituted body, guided by the sable leadership of Captain Shaw, which day and angle, heavy watch on our behalf against the devouring alemant'; and a serious, unremitting, and gallant war they wage. In the vary interesting statistics of some thirty-three years which Captain Shaw has published, we been that the men of the Brigade were tenanoged to 20,000 conflagrations, of which nearly ten thousand resulted in serious damage; yet the remainder, sincteen thousand colours and odd, were kept by skill and courage within the limits of 'elight loss.' During that period, out of this defensive army twelve men were killed, but, considering the number of years covered by the report, that would seem a light list, if the amplementance of over-exertion or exposure that resulted shally in disablement. Thus it may be concluded that from forty to fifty London firemen annually ander death or injury of sell and including which they so constantly show, from their chief down to every member of the rank-and file, it must be confessed that the Metropolitan Fire-brigade is actually one of the most chivalrons bodies of modern times. British acception for remove the firm appears of the rank-and file, it is the quality chiefly wanted to make gold Remest, for, ironical as the maxim may appear, at a great conflagration the chief thing required is codessat. Your Parisian sapeur-pompier is apt to fine and gesticulate, and your New-Yorker to waste his utility in eaths and noise; but any one who has witnessed Captain Shaw and his "merry usen' getting to work must have admired the imperturbable insular style in which the 'enemy' is surveyed, comprehended, tackled, and subdised."

France Engine, a machine used for first artinguishing purposes, by means of which water is projected with more or less force, and from varying distances, apon the premises on firs. The applications of water is so evidently the readient and best method of neutroning the destructive agency of first, that from the carliest times the method of applying its the best advantage has been a matter of great importance. These methods vary greatly in detail, extending from the simple bucket or other reseal capable of containing water, to the completely equipped steam first-signs of the present day. The surfaces record of what would now be termed a first-sighted a found in the "Spiritalia" of Hern, she flowershed in Egypt in the second contury before Christ, and allows a machine with two sylinders provided with an air-reseal and worked by alternating lesses, input the principle of the modern manual engith. From headants incides in the work of Virenteen. Againstices, and Pliny we glean that ancient Bosse, as well as some of the pro-

vincial cities, was provided with the messes of preventing and extinguishing fires, including statements and extinguishing fires, including statements regularly trained firesies, engines, bushes, and other implements; but we have no information as to the design of these angines. Where reiners sells at fires are known to have been more at angioung in the beginning of the sixteenth century, and in 1857 Solutius gives a description of a fire-engine made by John Haussch, which he saw infed at Muremberg in the previous year, throwing a jet of water an inch in diameter to a binght of 30 feet. Flexible hore, without which the use of fire-engines is extremely limited, own first practically applied by the brothers Van der Heide in Amsterdam in 1872. This was made of lestber, in lengths of 80 feet, joined at the ends with metal couplings, said suchled the joined at the ends with metal couplings, said suchled the six of the fire. Plexible suction-less by which the pumpe draw water direct from the supply, instead of its being carried to the engine in beakets, was added by them a few years later. Previous to the fire of 1866, London was provided with hand syringes or squirts, each holding about three quarts, worked by three men, two of whom held the heatrument, raising and lowering it for alternate defining an argue and replenishment, while the third worked the piston backwards and forwards. These, with similar machines placed in reservoirs owness, and worked by a lever, were the only firethird worked the piston backwards and forwards. These, with similar machines placed in reservoirs on wheels, and worked by a lever, were the only freengines available fore arreating the progress of the great fire. The date of the first application of the air-vessel to the modern freengine, is uncertain, the previous to the use of which the water was propelled in broken streams, occurs in the "Journal des Strans" for the year 1875. The principles to be employed in the constructed for the fire-engine heigh now each inhed, subsequent improvements consisted eliefy in perfecting the various details in the best application of manual abour, to more the pistons, and in the arrangement of the carriage, whesis, and axis.

Improvements were carried out in Prawes, Leopold in Germany and the caption of the sightested castnywham in England; the last free-engine have been chiefy in the arrangement of the whole machine, so that the hose, suction-pipes, and necessary implement are, with the firement, carried in or upon the engine, the horse properties and the successful of the engines are constructed with a great water through the successful. These pumps draw water through a families of the successful of the surface, and which forms the framework of the sugine. The sirvessel is placed between the pumps and the outlets, one on each side, to which the leasther delivery-hose is attached. The pumps draw water through a families of the sugine. The sirvessel is placed between the pumps and the outlets, one on each side, to which the leasther delivery-hose is attached. Merryweather & Gons, and Shand, Mason, & Go, both of London. The judges concluded their report by stating that, "whilst both sugines are good specimens of engineering, we are inclined, in accordance with the results indicated in the former part of this report, to give, after due consideration, our decided preference to Shand, Mason, & Co.'s engine. Capisia Shaw's report for 1869 shows that the Metropolitan Firsbriggle had then in use 2 floating and Mason, & Go. From this it will be seen that the external characteristics of the steam and manual fire-engines in its most approved form, as constructed by Shand, Maso

## Firefly

ation supported by public subscriptions, styled the Royal Society for the Preservation of Life from Fire. The following description of the Reseases employed by the society has been published by them: "The main ladder reaches from 30 to 35 feet, and can instantly be applied to meet second floor windows by means of the carriage lever. The upper hadder folds over the main ladder, and is reased easily into position by a rope attached to its lever-irons on either side of the main ladder; or, as recently adopted in one or two of the easipus, by as arrangement of pulleys in lisu of the lever-irons. The shore ladder for first floors fits in under the earnings, and is of the greatest service. Under the whole length of the main ladder is a canvas trough or bagging, made of stout sailcoth, protected by an outer trough of copper wire not leaving sufficient room between for the yielding of the canvas in a person's descent. The addition of the copper wire is a great improvement, as, although not tee canyles in a person's essecut. In a stantion of the copper wise in a great improvement, as, although not affording an entire protection against the canwas failing, it in most cases avails, and prevents the possibility of any one falling through. The soaking of the canves in alum and other solutions it also attended to; but this, while preventing its flaming, sannot remove the risk of secident from the fire charring the canvas. The available height of these escapes is about 45 feet, but some of them carry a short supplementary ledder which can be readily fixed at the top, and which in-creases the length to 50 teet." Although this form of ereases the length to 50 feet." Although this form of fire-escape has long been regarded as the best that could be used in a general way, the recent (Oct., 1871) disastrous occurrence, by which an heroic irreman lost his life through the burning of the canvas, whilst endeavouring to save the lives of others, proves that some improved and fire-proof form of material for the canvas shoot must be devised.

France, a name valgarly applied to those insects which have the power of emitting a luminous appearance from their bodies. (See GLOWWORK, &c.)

Figs., Grank.—The users of a composition of a highly combustible nature, said to have been invented about 670, by Callindon of Heliopolia, in the reign of Constantine III., emperor of the Rast, and used by the generals of that monarch with terrible effect against the files of the Saracens. The secret of its manufacture is now lost; but its chief ingredients are supposed to have been naphtha, pitch, and sulphur. It possessed the property of bursting into a raging flame on exposure to the sir, and could not be quenched by water. The only thing that would in any way counteract its destructive power was a mixture of vinegar, urine, and sand. It was attended with a disagreeable odour, and was hurled against the enemy from cross-bows, man-FIRE, GEREK. - The name of a composition of a highly

sand. It was attended with a disagreeable odour, and was hurled against the enemy from cross-bows, manonels, and other engines of was. The Greek fire was thrown thrice a day into the camp of the Crusaders when Aone was besieged by Richard L., casting the greatest amongance and injury to the Christian host.

FIRE CHARL BY. (See CROMAL.)

FIRE PLACE, in Build, the name given to the square opening that is left in the wall of a house for the reception of a stove or grate. It is formed in a shallow pier or abutment of masonry, which generally projects from the face of the wall into the apartment, having recesses on either side of it. The upright sides of the opening are called the jambs, and the head, which is usually in the form of a cambered arch, is termed the manutel. A broad flat stone is fixed immediately under the jambs, which, with another stone of distely under the jambs, which, with another stone of a similar kind, that is set directly in front of it, and on which the funder rests, is called the hearth; someon which the funder rests, is called the hearth; sometimes, however, the stone under the jambs is called the them, however, the stone under the jambs is called the think he had been as the subject of the stone under the jambs is called the sink, while the term hearth is applied to that which lies immediately in front of them. The wide square cavity inside the wall, and just above the fireplace, is gradually contracted in size half it becomes a small passage, which is termed the chimney, or flue. (See principle of the strength of the fireplace depends on the passage, which is termed the chimney, or flue. (See partments, to prevent the inconvenience likely to Flux.) This contraction is generally selled the size of the grate that its inches. In the will should be exposed to any great heat, gathering. The width of the fireplace depends on the inches. In the will should be exposed to any great heat, and wood as a non-conductor. No building eas remain in ordinary apartments, from 18 inches to 3 feet to interior, however well adopted it may be to resist fire aurroundable, the chimney-piece, consisting of pieces, or which great quantities of goods are stored, often frame. The vertical pieces are the state in the form of a frame. The vertical pieces are the state in the interior. This might be the firm the interior. This might be

## Fire-proof Buildings

support, is called the lintel. The lintel is surmounted by a broad shelf in the same material, called the manual-piece. The chimney-piece, whether in wood or marble, it frequently careed, and may be made a very bandsome and effective architectural feature in an instrile, it irrequency curves, and may be made a very handsome and effective architectural feature in an apartment. When chimneys were first introduced, the fire was kindled on the hearth, the fire! being supported on andirons, or fire-dogs, made of metal, and often chaborately ornamented. (See ANDIRON.) The opening above the hearth was long without say chimney-piece or ornamental dressing round it; while a projection, somewhat resembling a penthouse, or porch over a door, was brought forward from the wall of the spartment, directly over the fireplace, to act as a funnel, and to prevent the escape of the smoke into the apartment, to the discomfort of the inmakes. But when greater attention was paid to demestic architecture, the chimney-piece was introduced as an embellishment; and in massions built in the Elizabethan atyle, it consisted of a mass of carving and panels, which was generally carried up as far as the ceiling. The mantel-piece was introduced at a subsequent period, when the practice of adorning the wall shove the fireplace with carving was discontinued. It was at the fireplace with carving was discontinued. It was at first fixed at the height of five or six feet above the floor of the apartment, and was extremely narrow; in the present day it assumes the form of a broad thick slab. and projects considerably beyond the chimney-piece, being about 3 feet 9 inches, of four feet, above the surface of the hearth.—Ref. Nicholson's Architectural Dictionary.

FIRE POLICY. (See INSURANCE.)
FIRE-PROOF. (See FIRE-PROOFERG.)
FIRE-PROOF BUILDINGS.—To make a building entirely proof against the destructive action of five is manifestly impracticable; but the danger arising from fire may be obviated to a considerable extent by select-ing materials for building that are either incombustible ing materials for building that are etter incompositible or suffer less than others from the action of heat, and by paying proper attention to the construction of the building and the arrangement of the materials of which it is composed; that no wood-work, if timber be used in it, may be placed near enough to gas-pipes, or pipes communicating with heating apparatus, to be liable to ignition from explosion, or any other cause. All materials may be broadly classified as combustible All materials may be broadly classified as combustible and incombustible; including, under the former term, all kinds of wood, which fire will entirely consume; and under the latter, building stone, brick, cement, and though the action of heat may exert considerable influence upon them. Of the different kinds of wood in common use, oak, teak, and makogany, or any sort of hard wood, will not burn as rapidly and freely as deal. Of stones, some are more liable to injury from beat than others. Impactions and asset or remits will beat than others. heat than others; limestone, and even grante, will crack and fly to pieces if cold water be suddenly poured on them when in a heated state; but sandstone seems capable of offering more effectual resistance to the action of fire than limestone, and therefore better suited for fire-proof buildings. When iron is used for joists or girders, it must be remembered that it is liable to contraction and expansion under the influence of heat and cold, and that cast-iron beams will break if enddenly cooled by a jet of cold water when red-hot, if enddenly cooled by a jet of cold water when rad-hot, and that wrought-iron girders, in the same condition, are apt to give way under my endesive superincumbent weight. In constructing a fire-proof building, that is to say, a building in which an outbreak of fire will be attended with less destructive consequences to the building itself and the goods contained in it, than in one erected in the ordinary way, it is manifest that the use of combustible materials must be abandoned as much as possible, except for interior fittings, and to form himself and the superscript for interior fittings, and to form himself and the superscript for interior fittings, and to

#### Fire-proofing

counteracted, to a certain extent, by storing inflammable goods and materials liable to spontaneous combustion in small separate buildings, or in isolated compartments; care being taken, in their construction, to prevent the communication of the, breaking out in one part, to any other part of the building; for a large mass of fire in a building of great extent will do far more damage, in proportion to the building itself, than the heat arising from the burning of a small quantity of goods stored in a building of moderate size for reasons that are evident. To render an ordinary for reasons that are evident. To render an ordinary building, for commercial purposes, tolerably fire-proof, a stone staircase should be constructed, instead of one of wood, as the wooden staircase is too often the means of communicating the fire from floor to floor: the walls, also, should be of brick or stone of good quality; the joists, rafters, and roof of iron; and the floors composed of stone, slate, tiles, or bricks. In building rows of houses, at least nine inches of brick or stone should intervene between the ends of the joists let into the preserve of the side and considerate. into the party wall on either side, and openings for threplaces should always be arched with brick, as wooden bressummers in this position, and the ends of beams projecting into chimneys, have frequently proved the means of causing the destruction of many an old-

The means of causing the destruction or many an oldfishioned country mansion by fire.

Fire-proofing, the means of protecting plate,
money, papers, and documents of value, from the
action of fire, by the use of safes or fire-proof chambers,
and also of rendering woodwork and textile fabrics
capable of resisting its ravages. Iron boxes for the reception and safe-keeping of coin and papers have long been used; but when these were exposed to great heat, there was nothing to prevent the contents from becoming injured or consumed, if they consisted of books or parchment deeds. In 1834, a patent was taken out by a manufacturer of the name of Marr, for making safes capable of preserving anything placed within them from being damaged when the safe was surrounded by a fierce fire; and of late years the con struction of these iron repositories has been brought to great perfection by Chubb, Milner, Hobbs, and other makers. The general principle of making a fire-proof safe appears to consist in placing an inner case of iron inside an exterior framing of the same material, the intermediate space being filled with a composition that tends to prevent the heat from acting on the interior. The fire-resisting composition that is used consists of a variety of materials; such as powdered charcoal, sand bone-dust, gypsum, &c., used singly or in various com binations; and glass ressels containing some peculiar fluid ere sometimes added to the composition. The heat of a fire causes these glass vessels to crack; and the liquid contained in them is liberated and dispersed throughout the absorbent matter inserted between the inner and outer cases, and increases its capability of resisting fire. The iron of the exterior should be case-hardened, to guard against any attempt that may be made to force the safe open by drilling holes in it; and the lock should be so constructed as to be incapable of being blown open by the introduction of gunpowder. Every part should be made to fit closely and tightly together, especially the door, that no instrument may be inserted between its edge and the frame in which it fits, in order to force it open. The interior of the inner case should also be lined with some non-conducting matorial, such as the felt used for coating the interior of steam boilers. Since the introduction of fire-proof safes, they have been extensively used for the preservation of mercantile books and other documents; and testimonials have repeatedly appeared in the news and testimonials have repeatedly appeared in somewhat papers with reference to the effectiveness of their fire-resisting qualities, and the failure of every attempt made by burglars to force them open. An excellent method of rendering timber impervious to fire, is to over its surface with a solution of silicate of sods. When wood treated in this way is exposed to a figure to the solution of the solution of the solution. When wood treated in this way is exposed to a fierce flame, the heat draws the salt contained in the solution to the exterior of the timber, on which if forms a glazed coating, after having been nielted by the action of the fire. Muslins and all lines and cotton fabrics may be rendered fire-proof by dipping them in a solution of tungstate of sods. The greatsmert of this preparation is that the material which has been dipped in it may be washed and ironed repeatedly without deteriorating the

#### Firman

indestructible properties conferred on it by the tung indestructible properties conterged on It by the nung-state of soda; and it does not render the warp and woof brittle and rough to the touch, as tertile fabrics are which have been dipped in a solution of aitm or common satt, both of which substances possess quali-ties that will preserve linen and cotton goods from destruction by fire to a certain extent, but not so effectively. destruction by ure to a certain extent, but not so energitually as the tungstate of soda. It is cheap and easily applied, and its universal use would prevent many of the fatal accidents that so frequently happen from the ignition of light and inflammable fabrics. The solution of silicate of soda, mentioned above, should also be generally adopted as a wash for woodwork in houses, as generally adopted as a wash for woodwork in houses, as it effectually retards the action of the flames, which the resinous nature of the deal commonly used in build-ing is too liable to promote. The use of this prepara-tion would certainly prevent much of the destruction of life and property that arises from the rapidity with which fires invariably gain ground before effective them. First-Raising. (For Assow)

FIRE-BAISING. (See ARSON.)
FIRE-SHIPS, vessels filled with combustible matter to be sent against the shipping of an enemy lying at anchor in rivers or roadsteads, after having been set on fire in several places. They were frequently used during the wars of the last two centuries and the commencement of the present one, and often proved formidable engines of destruction. They are not so dangerous now, as one or two well-directed shots from one of the heavy guns now carried by ships of war would soon shatter to atoms any of the small craft that are generally used for the purpose. An attack with fire-ships was always made on a dark foggy night, which would allow of their being brought into close the state of the st proximity to the vessels it was desired to destroy. The wind and current being favourable, the helm of each was set in such a manner as to cause them to drift right against the enemy's ships when at anchor. When they had been brought as closely as possible to the doomed shipping, the crew lighted the fuses attached to the combustible matter on board, and took attached to the combustible matter on board, and took to their boats to get clear of the approaching explosion and conflagration. Formerly, ships were especially kept for this purpose in the British navy, but now it is a part of every gunner's duty to know how to fit out a fire-ship, if such a method of attack be contemplated. The fire-ships of the English did considerable damage to the Spanish Armada in 1888; and among other notable exploits with these destructive among other notable exploits with these destructive vessels may be mentioned the daring stack of the earl of Dundonald, then Lord Cochrane, on the French fleet lying at anchor in the Basque Roads, in 1809, which met with complete success, and that made by Sir Sidney Smith on the flotilla collected by Bonaparte for the invasion of England, off Boulogne, in 1804, which unfortunately proved a failure.

FIRE, ST. ANTHONY'S. (See ERYSIPRIAS.) FIRE-WORKS. (See PYROTECHNY.) FIRE-WORSHIPPERS. (See GUEBERS.)

FIRKIN, fir'-kin, a measure of capacity, which is equal to 9 ale-gallons, 7½ imperial gallons, or to 2,539 cubic inches.

FIRMAMENT, fir-mu-ment (Lat. firmamentum), was a term used in Ancient Astron. to signify the eighth heaven, or sphere in which the fixed stars were placed. It was called the eighth heaven because of the seven spheres of the planets which it surrounds. The firmument was supposed to have had two motions; one from east to west, round about the poles of the ecliptic, and east to west, round about the poles of the scliptic, and another and opposite motion from west to east. These revolutions it is said to complete in 25,412 years, or, according to Copernicus, in 268,600 years; at the end of which time the fixed stars return to the exact points that they occupied prior to their revolution. In the classies, the period was denominated the Platonic or great year. The word firmaneat usually designates the expansive arch over our heads, in which all the various phenomena of the stars and planets, appear to take uses. take place.

TREMAN, FERMAN, or FIRMAUN, fir-min' (Per., an order), is a word employed in Turkey to designate any decree issued by the Porte and authenticated by the sultan's own cipher or signet. Each of the ministers and members of the divan has the right of signing il mans relative to the business of his own department,

but only the grand vizier is authorised to place at their head the cipher containing the interlaced letters of the sultan's name, which alone gives them force. A decree signed by the sultan's own hand is called acti sherif. The name firman is also applied to a pasaport issued either by the Ports or a packs, enjoining the subordinate authorities to grant protection and sasistance to the traveller in whose favour it is granted. In

ance to the traveller in whose layour it is granted. In India, a written permission to trace is called a firman. FIRST-PRUITS (Lat. primitia) were the profits of every spiritual living for one year, claimed by the pope from all clerks appointed to benefices. In England this claim was first asserted in the reign of King John, and then only with regard to such clerks as the pope himself appointed to benefices; but subsequently they were demanded and taken by him from all clerks, by whomsoever appointed. By 26 Henry VIII. c. 3, the payment of first-fruits was transferred from the pope to the king, and their value fixed, as it is called, "in the king's books." Finally, Queen Anne gave up this branch of the royal revenue to the Church to form a perpetual fund for the augmentation of small livings. This is usually called Queen Anne's Bounty. and then only with regard to such clerks as the pope Bounty.

Fisc, or Fiscus, fisk, fis'-kus (Lat.), was the name given among the Romans to the private treasury of the sovereign, in opposition to the aversium, or public treasury; but afterwards, when the sovereign power became absolute, the two terms came to be synonymous. became absolute, the two terms came to be synonymous, and fiscus was applied generally to the property of the state. In Modern Law, on the continent of Europe, fiscus is applied to the public treasury, which is entitled to all fines, forfeited goods, goods without an owner, &c.; whence our term confiscation. The fiscus was entitled to many extensive privileges in civil as well as in criminal matters, and the term has come by degrees to be applied generally to the rights of the crown. In most of the German states there is an officer termed fiscal, who represents the government officer termed fiscal, who represents the government before the courts of justice, corresponding to the solicitor and attorney-general in Eugland.

Essal, fis-fell. pertaining to the public treasury or

(See Fiscus.) revenue.

Figs., fish (Sax. fisc), (Pisces), a name applied to animals exclusively aquatic, and occupying the fourth and lowest station of the section Vertebrata. The head is large, and set upon the neck without the intervention of any distinct neck; the body is usually of a spindle shape, tapering gradually towards the extremity; and the surface is usually smooth, without any irregularities which might impede the motion of the creature in its native element. In its general form, the body is usually rounded, or slightly compressed at the sides; sometimes this flattening proceeds to a much greater extent, so that the animal presents the appearance of a broad band, or oval disc, of which the edges correspond with the dorsal and ventral surfaces; in other cases, the flattening takes place from above downwards, producing a disc-like body, of which the upper and lower surfaces are dorsal and ventral. A fish may be shortly defined as an animal breathing through the medium of water, by means of gills; and in giving it our consideration, this latter apparatus is the most im-portant feature presented. It is situated on each side of the neck, and consists of numerous lamius fixed on arches. These lamine are covered with innumerable arches. These laming are covered with innumerable blood-vessels, and are so constructed as to present a considerable surface to the water, so that the blood may receive a sufficient portion of the exygen contained in that element. As the water in contact with the gills becomes deteriorated, it is necessary that a constant current be caused to flow over them. In most fishes this is effected by their taking water in at the mouth and expelling it at the gill-covers. The blood nance this is effected by their taking water in at the mouth and expelling it at the gill-covers. The blood, which is constantly sent from the gills to the heart, is distributed by means of the arteries to every part of the body, whence it returns to the heart by means of the veins. Animals of this order are for the most part furnished with an air-bladder in the interior of the body, which, as it is often connected with the oscillation of the property of the

and returns it into the veins, and the air which it incloses is probably derived from this fluid. By the dilation or compression of this sac, the specific gravity dilation or compression of this sac, the specific gravity of the fish is governed, and, acted on by a curious muscular apparatus, renders its possessor lighter or heavier than the surrounding element. The limbs of the fish are formed into fins; the fore-legs constituting what are termed the pectoral fins, and the posterior extremities, the ventral. Besides these, ordinary fishes are furnished with one or two dorsal fins, an anal fin, and a caudal fin, or tail. In some fishes, the dorsal or median fine are continuous round the whole posterior portion of the body; and this is the condition in which these organs first make their appearance, during the developor the body; and this is the condition in which these organs first make their appearance, during the development of the embryo in all fishes, the subsequent changes which fake piace in the arrangement of the parts being due to the unequal development of the bony rays, which support and stretch the membrane of which the fins are composed. The pectoral fin in all fishes consists of the same parts as the anterior limbs of any other vertebrated animal. Concealed within the skin, immediately helping the branchial companies is found a bright the branchial companies. distely behind the branchial openings, is found a bony circle, composed of several pieces, representing the shoulder-blade, with the coracoid bone and clavicle. This supports the bones of the arm, which are usually very short, and bear a series of carpal bones at their very snort, and pear a series of certai nones at their extremity; thellatter supporting a number of short cylindrical joints, whence the rays of the fin take their rise. The internal supports of the ventral fins never present such a close resemblance to the pelvis of the higher vertebrata as do those of the pectorals to the scapular arch. When situated in their normal position in the abdomen, they always consist of cartila-ginous or bony pieces, lying freely in the muscles, and quite unconnected with the vertebral column; but when the flus are advanced from this position to the neighbourhood of the pectorals, their internal supports are attached to the scapular arch of the latter members. The principal organ of motion is the caudal flu, or tail: by this it is propelled. The dorsal and rentral flus serve to balance it, and the pectorals to arrest its progress when required. The bones of fishes are of a less dense and compact nature than in the higher orders of animals, and always remain in an isolated state, similar to that of the embryo of the mammalia. The skeleton may be divided into four chief parts,the vertebral column, the head, the respiratory apparatus, and the limbs. The vertebral column consists of vertebre which are conose at each end and pierced in the middle; and, when joined together, the hollow space between each two is occupied by a gelatinous substance, which passes from one space to the next, through the hole in each bone. This hole is usually very small; but in some of the chondropterygians it is so large that the bodies of the vertebrae are mere To the vertebres are attached the ribs: in fact the ribs are the main support of all the other bones. The head varies more in form than in any other class of vertebrate animals. The same bones as those found in other oviparous animals are almost always traceable. other oviparous animals are almost always traceable. The upper jaw consists of maxillary and intermaxillary bones. In the greater number of fishes, the internaxillary bones constitute the chief portion of the upper jaw, the maxillary bones being placed behind and parallel to them. The lower jaw is composed, generally, of two bones on each side, the dental portion in front and the articular portion behind. The form of the body is for the most part such as mechanical printhe body is for the most part such as mechanical principles teach to be best adapted for moving with least resistance through a liquid medium. The surface of the body is either smooth and lubricous, or is covered by closely-imbricated scales, rarely defended by bony plates or roughened by hard tubercles, still more rarely armed with spines. The central axis of the nervous armed with spines. The central axis of the nervous system presents but one partial enlargement, and that of comparatively small size, at its interior extremity, forming the brain, which consists of a succession of ganglionic masses, most of them exclusively appropriated to the function of a nerve of special sense. The power of touch can be but feebly developed in fishes. The organ of taste is a very inconspicuous one; the which feeting the terms of the property of the terms of the state of the phagus by a tobe, must be regarded to secretain extent in the distribution of the framework supporting it, or the analogous to the lungs of the air-breathing vertebrats. This sac or air-bladder, however, has nothing to do lowing and breathing. Of the organ of hearing there is with respiration; it receives blood from the arteries, no ontward sign; but the essential part, the acoustic labyrinth, is present, and the semicircular canal, largely developed within the labyrinth, is without cochles, and is rarely provided with a special chamber, but is lodged, in common with the brain, in the cranial cavity. The eyes are usually large, but are seldom defended by eyelids, and never served by a lacrymal organ. The alimentary canal is commonly short and simple, with its divisions not always clearly marked, the short and wide quillet being hardly distinguishable from the stomach. The gancreas, for the most part, retains its primitive condition of separate caecal appendages to the duodenum. The heart consists essentially of one suricle and one ventricle, receiving the venous blood and propelling it to the gills; whence the circulation is continued over the entire body, in vessels only, which are aided by the contraction of the surrounding muscular fibres. The blood of fishes is red but cold, and is rarely elevated above the temperature of the surrounding element. The sexes of fishes, excepting the sharks and rays, offer no very decided external characters by which they may be distinguished. The respiratory organs, however, occupy more space in the males than in the females; and, on the other hand, the abdomen is larger in the females than in the males. The fecundity of fish is very wonderful, as the following table will show:—

Pisu.	Weight.		Weight of Spawn.	No. of Eggs.
Carp Codfish Flounders Herrings Mackerel Perch Pike Roach Smelt Sole Tench Lobster	oz. 25 24 5 19 8 56 10 2 14 40	dr. 5 4 10 0 9 4 64 0 8	2,571 12,540 2,200 480 1,223\(\frac{1}{2}\) 766\(\frac{1}{2}\) 5,1(0\(\frac{1}{2}\) 361 149\(\frac{1}{2}\) 642\(\frac{1}{2}\)	205,109 3,636,760 1,357,400 36,960 546,681 28,323 49,304 81,556 38,278 100,362 383,252 21,699

The salmon is far more productive than any of these; the ovarium of one female salmon will produce 20,000,000 eggs.—Ref. English Encyclopædia, Dallas, and the works of Jesse, Owen, Yarrell.

Fisheries, a term applied to various stations and

Fightheries, a term applied to various stations and localities around our own coasts and those of other nations, where the different shoals of fish used by man for food are to be found at certain seasons of the year; and where the business of catching or entrapping the selfsame fish is carried on by fishermen, an exclusive class devoted to the occupation. Fisheries or fishing-grounds have been often the subject of disputes and embroilments between different governments, and sometimes even treaties have been effected in their especial right; to instance which, it may be mentioned that a convention was signed at Paris on the 2nd of August, 1839, between France and England, to fit the limits of the oyster and other fisheries which approximated the coasts of the two nations. Fisheries are of the greatest importance to nations, and especially to England, whose extent is insular, and bounded on every side by the sea; because fish forms one of the articles of principal consumption as food, and is also an article of exchangeable nature with other nations in the path of commerce. The principal kinds of fish which have separate fisheries are whales, cod, ling, lake, herring, looksters, mackerel, oysters, pilchards, salmon, anchovies, sardines, sturgeons, and tunny. In this country our fishermen are in the habit of fishing for all thear, with the exception of the last four species; and each kind of fishery may be termed a separate instance of our national industry. The Br ish fisheries are carried on in various parts of our dominions. Whales are principally caught along the shores of Greenland, in Davis' Straits, and the South Seas, as well as near the southern portions of Australia and the Cape of Good Hope. With regard to those fisheries which are carried on infore closely to our own shores, that of the kerring, on the coasts of Scotland and along the British Channel, must be especially no-

ticed. The Caithness fishery is the most prosperous and remunerative of the Scotch fisheries, and the town of Wick may be said to be the centre of the therring fishery in that part. The average yield per boat engaged in fishing is about 100 crass, a cran measuring 45 gallons of ungutted herrings. The herring fishery commences in the month of May off the eastern side of Lewis, and continues into the month of June, or midsummer. It then spreads along the eastern or midsummer. It then spreads along the eastern and western shores of Scotland, reaching Caithness by August. During the autumn the shoals are off Yarmouth, and there continue during a portion of the winter, by which time they commence to work their way up to Lewis once more, where they reappear again in the spring. The herring is fished for by driftnets, which are composed of several lengths, and by trawl nets; the latter, however, are the most useful. The Irish herring fisheries are not so productive as the Scotch, but they are yearly stimulated by public grants of money for their furtherance; and the same may be said of all other species of fisheries in Ireland; this is owing not so much to their support. this is owing not so much to their unprofitableness as to lack of industry in their prosecution. The pilchard fishery is carried on along the coasts of Cornwall and Devon, and is of great importance in the trade. The pilchard is caught in the months of August, September, November, and December, and is salted and packed for exportation. The quantity of the pilchards exported by us to the Mediterranean and other foreign markets is about 30,000 hogsheads per annum. markets is about 30,000 hogsheads per annum. The salmon fishery is carried on chiefly on the rivers and estuaries of Scotland and Ireland. Aberdeen in Scotland, and Cork in Ireland, are the chief salmon stations, from whence the fish is sent to various parts of the kingdom. (For a description of the salmon, see article under that heading.) The cod, ling, and hake fisheries are carried on along Scotland and Ireland, and about the banks of Newfoundland. These fisheries themselves may be said to date their origin fisheries themselves may be said to date their origin from the discovery of the Portuguese, in the year 1500, and they are the sole support of the dwellers in that unproductive land. The quantity of cod, ling, and hake cured and exported from Scotland and the Isle of Man in the year 1854 was 109,684 cwt. cured dried, 6,166 cwt. cured in pickle, and 19,557 cwt. exported, which were of dry cure. The mackerel and other minor fisheries are carried on along our own coasts, and do not need separate mention. The shell-fish which are so much consumed by us are found in the Channel islands and about the English Channel. (For whalefishery, see descriptive article on the whale.) A rough estimate of the total value of the foreign and domestic fisheries of Great Britain would give a sum of about £6,000,000 per annum, although they have indeed been stated to be worth £8,300,000 annually. FISHING. (See ANGLING.)

FISHING. (See ANGLING.)
FISHINGS. (See ANGLING.)
FISHINGSTEES, fis-se-roy-treez (Lat. findo, I cleave;
rostrum, a beak), the name of a tribe of birds, consisting of the swallows, swifts, and gostsuckers. They
are distinguished by having the bill short, broad,
depressed, slightly curved, without any tooth, and so
deeply cleft as to give pecuhar wideness to the gape;
a structure of great use to birds which prey so exclusively on insects taken on the wing. On account of
the food on which they subsist, all the fissirostres migrate from northern countries towards the close of
autumn, and return again in spring. Like the raptorial order, or birds of prey properly so called, the
fissirostral tribe is capable of a binary division into
diurnal and nocturnal species.

Fistula, fis-tu-li (Lat., a pipe or reed), in Surg., is a long and sinuous ulcer, having a narrow opening, sometimes leading to a larger easity, and which has no disposition to beal. The most common form of this disease is the fistula in ano, the sinus extending into the cellular substance about the snue, or into the rectum itself. It is the result of abecesses formed in the cellular tissue around the rectum, and which having burst or been opened, are prevented from healing by the action and irritation of the sphincter ani. They are divided into two kinds,—complete and incomplete, or blind; the former having two openings or outlets, the one externally, the other into the rectum; the latter having only one, and being divided into blind external, according as the

opening is external or internal. This disease is commonly attended with intense pain, especially when passing the fæces, and there is an irregular discharge of purulent matter, which is sometimes mixed with blood. The treatment consists in making a complete cuoca. The treatment consists in making a complete division with the knife of the whole of the parts between the fistule and the bowel, and the edges of the wound are kept spart by lint, in order to allow the cavity to fill up by granulation. A fistule lacrymalis is a disease of the lacrymal sac, caused by an obstruction to the flow of tears along the nasal duct. The symptoms of this disease are a watering of the are with a dwyness. this disease are a watering of the eye, with a dryness of the corresponding nostril, a distension of the lacrymal sac, and a discharge of muco-purulent fluid mixed with tears, from the puncts lacrymalis, when the sac is compressed. In the earlier stage of this disease, when there is only a distended state of the lacrymal sac, a cure may be effected by the application of leeches and fomentations to the eye, with the use of astringent ointments to the edges of the lid. In the more advanced stages, however, where there is inflammation and suppuration of the sac, or where a fistulous opening has been formed in it, by the escape of purulent matter, an operation becomes necessary for its removal. is effected by making an incision with a sharp-pointed knife into the lacrymal sac, and then passing a probe downwards into the nasal duct; after which a silver instrument called a style is inserted, and allowed to remain until the inflammation, which produced or accompanied the abscess has subsided. Salivary fistula is a fistulous aperture in one of the salivary ducts, opening externally, and through which the salivary escapes. It is generally caused by a wound, which, if recent, a cure may be effected by merely bringing together and uniting the edges of the wound; but if of some standing, a free canal ought to be formed for the discharge of the saliva into the mouth. In fielula in peringo, which is almost always accompanied with a stricture of the urinary passage, the fluid passing out stricture of the urinsry pussage, are mine passage out of the external opening of the sinus, an operation is necessary, which will require the aid of a competent surgeon. Fistules generally require very skilful treatment, and are often extremely difficult to close; and though not in themselves dangerous, they are not unfrequently attended with fatal results, arising out of the constitutional depression, which they occasion by the long-continued wearing pains, and the drain upon the system, in consequence of the protracted discharge. Fistula in ano is often observed in consumptive patients.

Fixtula in ano acolten observed in consumptive patients.

Fitz, fits (old Nor.), signifying son, and evidently a corruption of the Latin filius. It is prefixed to proper names, like the Scotch Mac, the Irish O, and the oriental Ben, to signify descent; as in the names Fitzwaller, Fitzwilliam, Fitzherbert. It has also been employed in recent times to denote the natural sons of the property of the kings and princes; as in Fitzroy, Fitzjames, Fitzclarence.

FIVE POINTS, THE, in Theol., are the five principal points of controversy between the Calvinists and Arminians. (See CALVINISM.)

FIXED AIR, fiked (Fr. fixer, to fix), in Chem., an old term for carbonic acid gas.

FIXED OILS. (See OILS.)

FIXED STARS, the common name given to all stars in the heavens, with the exception of the planets. They are so called because they appear to us to be stationary in the broad field of the heavens, having no apparent motion, and always preserving the same relative position with regard to each other. They are supposed to be the centres or suns of other systems, similar to our n. Sirius, the dog-star, in the constellation Canis Major, which is the brightest of all the stars, is considered to be nearer the earth than any other; and the distance of this from our planet is computed to be not less than nineteen millions of millions of miles. The fixed stars have been grouped into separate clusters called constellations, and divided into six classes accance conscensions, and divided into six classes according to their respective apparent magnitudes, the largest and brightest being called stars of the first magnitude, those that are next in size and lustre stars of the sixth magnitude are the smallest that are visible without the aid of a telescope.

the light. The principal fixing agents are hyposulphite of sods, which may be used either for glass or paper pictures, and cyanide of potassium, which can only be used for the former. (See PHOTOGRAPHY.)

FIXTURES, fike tures, in Law, are things annexed to houses or lands, which become, immediately on annexasame laws as apply to heritable property. The question as to what are or are not fixtures is of some importance, as determining the rights of landlord and tenant, heir and executor, &c. Fixtures in general are personal chattels let into the earth, or cemented or otherwise fixed to some erection previously attached to the ground, and are thus legally immovable. If they the entirely clear of the soil, they are not fixtures, and may be carried off at pleasure. Hence a tenant may construct erections,—even barns, sheds, and the like, upon blocks, rollers, pillars, or plates, so that they shall not be deemed fixtures but remain movable charten. tels. The general rule is, that whenever a tenant has affixed anything to the premises during his term, he cannot again sever it without the landlord's consent. To this rule, however, various exceptions have been made in favour of what are termed trade fixtures. A tenant may safely remove such things as he has fixed to the freshold for purposes of trade or manufacture, provided the removal cause no material injury to the As regards agricultural fixtures, it is provided by 14 & 15 Vict. c. 25, that if any tenant of a farm or lands shall, with the consent in writing of the landlord for the time being, at his own cost erect any farm-buildings, either detached or otherwise, or put up any buildings, either detached or otherwise, or put up any other building, engine, or machinery, either for agricultural purposes or for the purposes of trade and agriculture (which shall not have been put up in pursuance of some obligation in that behalf), then all such building, engines, and machinery shall be the property of the tenant, and shall be removable by him, notwithstanding that the same, or any part thereof, may be built in or permanently fixed to the soil; so as the tenant, in making such removal, do not in anywise injure the land or buildings belonging to the landlord, or otherwise do put the same in like condition as they were in before the erection of anything so removed. But the tenant, before making any such removal, must give the landlord or his agent one month's previous notice in writing of his intention to do so; and if the landlord or his agent elect to purchase the things proposed to be removed, then the tenant's right to remove the same shall coase, and the value of the things shall be ascertained by two referees, one to be chosen by each party, or by an umpire to be named by such referees, and shall be paid or allowed in account by the laudlord who shall have so elected to purchase. Another exception to the general rule is in favour of such fixtures as are put up for ornament or domestic use, as hangings, stoves, &c.; but not such as have become part of the tenement, and constitute permanent improvements. The distinction, however, is often very nice, and it is difficult to define it in general terms.—Ref. Amos and Ferand On Fixtures.

FLACOURTIACEE, flá-koor-te-ni'-se-e, named after M. de Flacourt, a director of the French East-India Company, in Bot., a synonyme for Bixaceæ (which

see).

FLIG, Adg (Sax. fleegan, to wave in the air), the name given to pieces of cloth, or bunting, of various colours, and often bearing various devices, that are hoisted in conspicuous places on poles or at the masthead of vessels, and allowed to float on the breeze for different purposes. The primary object of a flag is to denote nationality, and it is more especially used for this purpose at sea, to allow commanders of vessels to this purpose at sea, to allow commanders of vessels to show others to what country their ship belongs. The use of fiags is probably of very early date, families and tribes, as well as nations, being distinguished, in the early ages of the world, by emblems embroidered on a small source banner. We are told in Numbers ii., small square banner. We are told in Numbers in that in the wanderings of the Israelites in the wilder nitude, those that are next in size and lustre stars of ness, they were ordered to pitch every man "by his own standard, with the ensign of his father's house;" magnitude are the smallest that are visible without the sid of a telescope.

Fixing, in Phot, a term applied to the cleaning of photographs from the sensitive layer not acted on by 850

Flake-white

adopted a green standard, which, with the addition of a creacent, is still the national flag of Turkey; and about the same period, the white horse of the Saxons, perpetuated in the armorial bearings of Hanover, and the black rayen of the Danes, were well-known ensigns that floated over many a battle-field on English soil. The ustional flags borne by the principal nations of the world at the present time will be found in the plate of "Flags of Ail Nations," in vol. I. of this work. Of the flags peculiar to Great Britain, the principal is the Royal standard, consisting of the armorial bearings of England, Scotland, and Ireland combined, which is England, Scotland, and Ireland combined, which is hoisted wherever her Majesty happens to be residing; or on vessels, when the queen or any of the royal family is on board. The Admiralty flag consists of a gold anchor borne on a red field; and the national flag, known as the Union Jack, consists of the red cross of St. George, and the red and white saltires of St. Patrick and St. Andrew, combined, on a blue field. The ship in which the admiral of the fleet happens to be always carries the union jack. When this flag is hoisted by a merchant ship, it is distinguished by having a white border round it, and is then called a merchant jack. There are also three other flags, which are used to distinguish admirals of different ranks in the navy, known as the red, white, and blue which are used to distinguish admirals of different ranks in the navy, known as the red, white, and blue ensigns. The red, or British ensign, is a red flag with the union jack in the upper corner of the end attached to the haulyards; the white ensign is a white flag with a red cross; and the blue ensign a blue flag, both having the union jack in the same position that it occupies in the red ensign. The grade of an admiral is further distinguished by the must at which be carries his there a full admiral of the rad white, or blue, hearing his flag; a full admiral of the red, white, or blue, bearing his flag at the main-mast, a vice-admiral at the fore-mast, and a rear-admiral at the mizen-mast. Flags of various shapes and colours are used as signals for various shapes and colours are used as signals for communication in the royal navy and British mer-chant service, a new code of signals having been lately introduced to superseile that invented by Captain Marryatt, the well-known novelist. Different signifi-cutions are also attached to plain flags of one simple colour; thus, a yellow flag indicates that there is sickness of a dangerous character on board the vessel which bears it, or that the ship is performing quarantine; a white flag is well known among all nations as a flag of truce, and betokens a desire for a temporary cessation of hostilities, for the purpose of communica-tion between hostile parties, or for burying the dead slain in battle; a black flag, on the other hand, is the emblem of piracy, or betokens a determination, on the part of those who hoist it, to resist to the last, and to give or taken no quarter. When a flag is hoisted half-mast high, it is a mark of mourning: when it is hoisted upside down, it forms a signal of distress. A blue flag, with a source white covers a signal of distress. with a square white centre, called the blue-Peter, is hoisted when a vessel is about to sail, and is the signal of departure. A short triangular flag is called a burgee; a longer flag, of the same shape, a signal pendant; a square flag, with a triangular piece cut out of the end furthest from the haulvards, with the point turned towards the centre, a cornet; and a very long narrow flag, resembling a strip of ribbon tapering to a point, which is borne at the mast-head, is called a pendant.

FLAG, in Bot., a general term for a number of endo-genous plants whose leaves are sword-shaped. (See Acores and Ints.)

FLAGELLANTS, füğ-el'-lânts (Lat. flagellare, to beat), the name of a sect of religious fanatics that sprang up in Italy about the year 1260. They were so called from the flagellations or whippings which they administered to themselves, the leading doctrine of their creed being that by mortifying the flesh in every conceivable manner they propitiated the wrath and gained the favour of the Deity. Sects or bodies of persons holding this doctrine, and practising whipping and other mortifications of the flesh, had appeared at various times in the earlier history of the Charch; but this was the first occasion on which they made a prominent figure. People were no longer satisfied to perform these acts in private, but took to practising them in public, by way of greater humiliation. They FLAGELLANTS, finj-el'-lants (Lat. flagellare, to beat), them in public, by way of greater humiliation. They formed themselves into large bands or companies, and went about from place to place, carrying banners and

crosses, singing penitential hymns and whipping themselves until the blood flowed. In 1201 they passed into Germany, and there made many converts; but on account of their irregularities and disorderly proceedsings, a general outory was raised against them, and they were at length put down. The second great out-break of this manis took place after 1343, when that terrible scourge the black death had swept over Europe and carried off so many persons. The imaginations terrible scourge the black death had swept over Europe and carried off so many persons. The imaginations of the people, already excited by the pestilence, were ready to seize upon this superstition, which spread rapidly through Germany, Switzerland, Holland, Sweden, and even England. The scenes of the previous century were re-enacted with even greater excesses than before. Men and women indiscriminately now armaged in public halfonked, and nuderwent these than before. Men and women indiscriminately now appeared in public helifonked, and underwent these self-indicted acorgings. They held that flagellation was of equal virtue with baptism and the Lord's Supper; that forgiveness of sins was to be procured by it without the blood of Christ; that the law of Christ was soon to be abolished; and that a new law, enjoining a baptism of blood, to be administered by whiting was to take its when. They were condemned whipping, was to take its place. They were condemned by a bull of Clement VI., and other severities were practised against them, until at length they disappear. Again, in the year 1414, a new troop of these fanatics make appearance in Germany, under the leadership of one Conrad Schmidt. They were even more with in their extravagances than their predecessors, rejecting all forms of worship, and holding that faith and flagellation were alone necessary to salvation. They were everywhere persecuted, and many of them were burnt as heretics; among whom was their leader Schmidt; but it was with difficulty that their system

was at length suppressed.

Fig. 2. Additional many content of the first system ment of the flute kind, played on by means of a mouth-piece at the upper end. It is generally made of box, ebony, or other hard wood; but sometimes of ivory, and has a clear and shrill tone. Its compass 

FLAG OFFICERS, a class of officers in the navy above the rank of captain, who have commands of fleets. Flag officers are divided into three ranks, and each of these three ranks into three different classes. The ranks are red, white, and blue, and the classes are admiral, vice-admiral, and rear-admiral. Flug officers may therefore be considered as numbering in all nine different ranks, which are as follows :- Admiral of the of the white, and of the blue; vice-admiral of the red, of the white, and of the blue; thirdly, rear-admiral of the red, of the white, and of the blue. The admiral of the red, of the white, and of the blue. The admiral wears his flog at the main; the vice-admiral at the fore; and the rear-admiral at the miren. There is also an admiral of the fleet, who, if in command of a squadron, would wear his flag-a union jack-at the main. commodore is occasionally a flag officer, and he is distinguished by wearing a broad pennant.

FLAG-SHIP, the nautical term applied to the line-of-battle ship, frigate, or other ressel, which carries the flag officers in command. FLAIL, flail (Ger. fleeel. Lat. flagellum). a wooden

flag officers in command.

Frail, flail (Ger. flagel, Lat. flagellum), a wooden implement employed for threshing ourn by hand; consisting of two parts yis; the handle or hand-staff, and the swiple, or part which strikes the corn; these two portions being joined together by thongs of untanned leather, called captines or coppins. It is now almost superseded by the threshing-machine. (See Theresh.

FLAKES, finite (Aug. Sax., a layer or stratum), in Hort., carnations with large stripes of colour. (See

FLARK-WHITE, a pigment, consisting of a preparation of carbonate of lead. It is much used in painting in body-colours, being a substance with which transparent colours derived from vegetable matter may be mixed and rendered opaque, so that they may be laid on veliuns or paper in the form of an even coating, possessing some degree of thickness and consistency. It is also used for putting in the high lights in drawings in water-colours, and crayon drawings in two or three tints; but it is apt to become brown and discoloured in course of time. Chinese-white, or marine-white, both of which are preparations of carbonate of zinc, are far better for this purpose and as a vehicle for preparing body-colours from simple water-colours, as they afford a white pigment of the purest nature, which will always retain its brilliancy unimpaired and untarnished by exposure to the atmosphere.

FLANBEAU, fdm'-bo (Fr.), a kind of torch made of thick wicks, covered with wax, and used at illuminations and processions in the streets at night. A flambeau

and processions in the streets at night. A flambeau usually consists of four wicks or branches, about an inch in thickness and three feet long, made of half-twisted hempen yarn. These are suspended, and white or yellow wax is poured over them from a ladle, until

or yellow wax is poured over them from a ladle, until a coating of the required thickness is obtained.

FLAMEDYANT, fläm-boy'-ant (Lat. flamma, a fisme), the name given to French ecclesiatical architecture of the 15th century, derived from the beautifully carved tracery of the windows, which appears to run in waving lines somewhat resembling the various directions taken by lambent flames of fire. This style of French Gothic architecture is also known as Opiud. Tertiare: it corresponds in a great measure with the Perpendicular English or third Pointed style; but it is characterized by far more elaborate ornamentation; characterized by far more elaborate ornamentation; and objects of rectilinear form and outline, which constitute such a marked feature of the latter style, are not so frequently introduced.

Flams, flams (Fr. flamme), in Chem.—Flame may be defined as a shell of incandescent matter surrounds.

ag a mass of combustible vapour. To produce flame it is therefore necessary that the burning body should be capable of volatilization just below the temperature at which it undergoes combustion. Charcoal or iron at which it undergoes combustion. Charcoal or iron will burn with a steady glow, more or less luminous according to the medium in which they are burnt, neither of these substances being susceptible of volatilization at the temperature at which combustion takes place. A piece of wood or paper, on the contrary, burns with a large luminous flame, in consequence of the combustible matter of which it is composed vising in vacour or becoming converted into posed rising in vapour or becoming converted into mixed gases at the temperature required for kindling the substance. Flame is, in fact, produced whenever a continuous supply of inflammable vapour or gas is made to combine with a supporter of combustion, such made to combine with a supporter of combustion, such as the atmosphere, at a sufficiently elevated temperature to cause ignition. That flame is hollow may be easily proved by several simple experiments. If a little spirits of wine or other inflammable liquid be ignited on a watch-glass, and a straw held across the flame, it will be found that the straw is charred only at the edges of the flame, the intermediate portion remaining uniquired. A still more instructive proof is afforded by placing a piece of class this or telesco-mine afforded by placing a piece of class this or telesco-mine. remaining uninjured. A still more instructive proof is afforded by placing a piece of glass tube or tobacco-ripe nearly upright in the middle of the flame of a candle, when the vapour and gaseous matter rising through the wick from the melted tallow will ascend through the pipe, passing out at the upper orifice of the tube, where they may be kindled. The heating power of a flame is in direct proportion to the energy of the chemical action that takes place, those flames being hottest and least luminous which proceed from gases containing no solid particles, as in the case of a mixcontaining no solid particles, as in the case of a mix-ture of oxygen and hydrogen in the proportion neces-sary to form water, which is one of the hottest flames we have at our command. The most luminous flames are from gases which contain just sufficient solid matter to give the maximum of incandescence without matter to give the maximum of incandescence without any of its particles passing away unburnt. Oleflant gas and the ordinary coal-gas are good examples of this as compared with the oxyhydrogen flame, which contains no solid matter on the one hand, and the contains no solid matter on the one hand, and the farm of pitch or turpentine on the other, which contains too much carbon, the excess passing off in the form of smoke. The flames used for illuminating purposes are all produced by the combustion of compounds containing carbon and hydrogen. Besides the proper proportions of gaseous and solid matter contained in illuminating substances, care must be taken to regulate the supply of air. By

paying proper attention to this, many substances are greatly improved in their illuminating properties, while others are made to give an intense light, which could not otherwise be burnt. The Argand burner and chimney, as applied to gas and camphine, are examples of this. (See Argand Burner.) The fiame of an ordinary candle is a good illustration of the phenomena of flame. At the lower, or blue portion, the hydrocarbon contained in the gases resulting from the decomposition of the tallow by heat, mixed with so much atmospheric air that the whole of the carbon unites with hydrogen none being left to sive incandescence. atmospheric air that the whole of the carpon unities with hydrogen, none being left to give incandescence. Passing higher up, we see a dark part, which consists entirely of the gaseous matter formed by the decomposed tallow. This, on being heated by the blue portion of the flame, rises in luminous vapour until it comes in contact with the oxygen of the atmosphere, when it is the second of the second or the second of the second or the second of the second or th when it unites with it, forming a bright but not luminous envelope to the incandescent carbon,—the products of the combustion being water and carbonic soid. The influence of solid matter in increasing the luminosity of a flame may be aptly illustrated by aprinkling a little powdered magnesia in the flame of a spirit-lamp, (See

GAS, ILLUMINATION.)

FLAMEN, Adi-men (Lat.), the name given to any Roman who was devoted to the service of one particular god. Each flamen received a distinguishing that the particular god that deity to whom he minisepithet from the name of the deity to whom he ministered. The most dignified were those of Jupiter, Mars, and Quirinus, and were called respectively Flamen Dialis, Flamen Martialis, and Flamen Quirinalis. The name is derived from the cap or fillet which they were on the head. When the emperors were deified, they also had flamens.

FLAMERGO, fla-min'-go (Sp. Port, flamenco), (Phonicopterus ruber, Linn.).—This bird inhabits the warm climates of Asia, Africa, and America, and is one of the climatee of Asia, Africa, and America, and is one of the most remarkable of aquatic birds. Its height is about four feet. In its first year it is of one colour,—greyish white; in its second year, the white is purer and the wings are tinted rose-colour; in the third year it attains its full plumage,—wings roseste, back deep soarlet, and quill-feathers jet black; and as the bird grows older, these colours increase in tone. The neck is slender and of great length, equalling that of the legs, which are about two feet. The head is small and round, and furnished with a hill nearly seren inches long, which is are about two feet. The head is small and round, and furnished with a bill nearly seven inches long, which is higher than it is wide, light, and hollow, having a membrane at the base, and suddenly curved downwards from the middle. as if broken. The lower mandible, which is the larger, is so adjusted as to fit the angle with its edges, its under surface being greatly arched downwards. The edges of both mandibles are serrated. In convention there would have at the archiver at least the same and the services at least the same and the same archive. uownwards. Ine euges of both mandibles are serrated. In operation, these mandibles act like a strainer, allowing the water to escape, but retaining any sort of prey the flamingo may capture. Its food consists of small fish and water insects, which it fishes up by means of its long neck, turning its head in such a manner as to take advantage of the crock in its head. take advantage of the crook in its beak. In searching among the mud at the bettom of the water for food, the upper, not the under, mandible is applied to the ground. In that situation the inferior mandible is uppermost, and by its motion works the disturbed water through the two. The tongue is large and fleshy, betokening an acute sense of taste. The flamingo's mode of incubation is peculiar. The great length of its legs, com-bined with the fact that the bird never sits down, but rests standing on one leg, renders a nest of the ordinary construction altogether unsuitable; so the flamingo constructs a tallish cone of mud, with a cavity at the top, and in this cavity the eggs are laid, and straddles across the whole, so that her feet rest on the ground

and the under part of her body on her eggs. The latter are white, and rather larger than those of the goose. Flance, flam (of doubtful derivation), the metal rim bent over in gas-pipes, water-pipes, &c., in order to join on other lengths of the same. The term is also

#### Flannel

from which a fire may be directed against the side or flank of an attacking party. Thus, the flanks of a bastion are those parts of the rampart and parapet which connect its faces with the extremities of the curtains of the enceinte on either side of it. On reference to the diegram of a front of fortification given in the article on that science (see FORTIFICATION), it will be seen that a fire from the flanks is effective in preventing an attacking party from effecting a lodgement at the foot of the curtain that lies between them, which might be done with comparative case and security if these portions of the work did not exist. A fire from the flanks of any bastion enfilades the ditch at the foot of the

FLANNEL and FLANNEL MANUFACTURE. (Sc WOOL MANUFACTURE.)

FLAT, flife (Du. plat), in Mus., a character employed to lower or depress any note or notes in the natural scale one half-tone. An accidental flat is one which, although not occurring at the commencement of the staff, is inserted in any other part of it, and only affects the har in which it is precal.

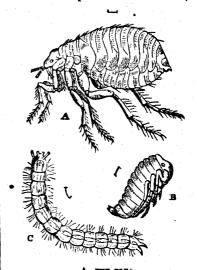

the bar in which it is placed.

Fiatulency, fat-u-lense (Lat. flatus, a blast), in Med., is a morbid collection of gases in the stomach and bowels, commonly arising from indigestion, or from indulgence in certain kinds of vegetable food. When, from any weakness in the digestive powers, food remains in the stomach in an undigested state, fermentation takes place, and gases are formed. Flatulency is ususily symptomatic of other diseases,—indigestion, colic, cholers, hysteria, or nervous debility. For its curre, carminatives, tonics, and aperients are resorted to; and strict attention to diet is necessary, taking only such food as is light and easy of digestion, and avoiding all oleraceous vegetables, peas, beans, and flatulent fruits. Weak brandy-and-water, as a beverage at dinner, is also very beneficial. When the pain is excessive, hot applications to the stomach and friction will frequently afford considerable relief.

FLAX, flaks (SAX. fleax, flex), the fibre of the Linum unitationum, separated from the woody portion of the plant, and ridded of any impurities, after which it is spun into thread, from which state it is woven into linen. (See Linum.) It is supposed to be the fruit of Eryptian discovery, as the coverings of the mummies found in the pyramids all attest to their being composed of what is generally termed flax. The flax-plant is of slender form and of annual growth. It reaches generally the height of from two to three feet, and has small lanceolate leaves, which terminate at the extremities in delicate blue flowers, which are afterwards replaced by seed-vessels, containing each ten seeds. The plant itself grows over the whole extent of Europe, Asia, and America. The time for gathering the flax is when the leaves begin to drop off, and when the stalk has a vellow appearance. The stalks are them stripped, and the seed-boils carefully gathered and stored up for the next year's supply. The first process in the preparation of the flax is to steep the stalks in water until decomposition and fermentation takes place; that causes the glutinous matter which binds the woody and fibrous parts together to become separated. The duration of this process is from six to twenty days, according to the quality of the water employed and the state of the flax plant. After the first process, the stalks are dried, and in this state they may be kept in sheaves for years. After the flax habeen "retted" (as the first operation is called) and dried, it is broken repeatedly, beaten with a flat piece of wood, and also "soutched," in order to remove all the woody particles from the fibre. The last operation is termed "heckling," which consists in combing the flax through and through, in order to remove all the spinner's hands. This process is required as much to straighten the fibre as to lessen any knots or irregularities in the flaments. The action of the heckles divides the scutched flax into two portions, the long termed "line," and the wo

#### Flea

FLBA, fie (Ang.-Sax.). — The proper position of this insect in entomological classification has been the subject of much dispute. By many authorities, including the distinguished names of Latreille, Kirtyg, and Spence, the fleas are considered to form a distinguished naturalist treating of them under the order Siphonaptera, and the latter, the order Aphamiptera. By others, they have been arranged with the order Diptera, but with little reason; for in certain important characteristics they widely differ from them. It has been truly remarked, that "it is highly probable, when this group is better known,—when the numerous insects allied to the fleas are more common in our cabinets, it will be found that they do not constitute an order by themselves, but are aberrant forms of the other well-established orders. In these, there is a certain degree of uniformity, as regards number, variety of habits, &c., which cannot but lead us to doubt the validity of the so-called orders, containing only one or two genera and but few species, such as the present orders." The curious structure of the flea has doubtless greatly contributed to perplex and hinder those who have sought to find its correct genera.

-PUPA OF DITTO. C-LARVA OF DITTO.

(All magnified.)

irritans), which is, unfortunately, very numerous in this country. The body of the files is protected by a horny covering, composed of segments, which are very well defined,—those of the thorax are always disunited. Its mouth is suctorial, formed of three pieces, inclosed by two articulated lamines, which, when united, form a cylindrical or conical proboscis, the base of which i protected by two seales. Although, to all appearance, apterous, the fice possesses the rudiments of wings, which are four in number, in the form of borny plates on the sides of the meso- and meta-thoracic segments, the hindmost pair being somewhat larger than the other. Its head is small and compressed, on each side of which is a small round eye. The most singular organs of the fice are the two fine-pointed mandibles of the mouth, which, in combination with another sharp organ (supposed to represent the lantum), constitute the powerful attacking instrument of the insect, which permits it to pierce the hard skin of its victim with remarkable facility. Situated on the anterior part of the head, are two four-pointed organs, which were formerly supposed to be the antenne, but now more correctly considered to be the maxillary

palpi. The antenna are very minute, and concealed beneath a rake-like plate on the sides of the head behind the eyes. The legs are very strong, more par-ticularly the hinder ones, which are used by the flea in its extraordinary leaps. This insect undergoes a complete metamorphosis; the larva is an elongated complete metamorphoeis; the larve is an elongated footless grub. On arriving at the pups state, which occupies about twelve days, it incloses itself in a silken cover, and in a few days assumes its mature condition. Besides Pulex irritans, there are several other species peculiar to different animals. The dog possesses such a parasite (P. Canis); also the martin (P. Hirsadinis); the mouse (P. Musculi); and the mole-flea, a large variety (P. Tulpa). A great pest of the West Indies and South America is the chegoe or ligens. (Res Chunga)

Figer. (See Chicoe.) fiche, an arrow), a small work, so called because its outline resembles the shape of a broad arrow. It consists of two faces meeting in a point, and forming a salient angle. This defensive nothers is sometimes thrown up during a siege, to enable the besieged to pour an enflading fire along some of the trenches of the enemy; or it is constructed in connection with the main works of any fortified place, to command any small valley or glen that might otherwise be made available by the enemy as a

means of approach to the fortifications.

means of approach to the fortifications.

Fibecs. (See Wool.)

Fibecs. (See Wool.)

Fibecs. OBDEOFFIBE GOLDEN, flees (Sax. flees).

This order, one of the most distinguished in Europe, was founded in the year 1430, by Philip III., duke of Burgundy. One of its privileges conferred on the successors of Philip the title of hereditary grand master of the order; and, in consequence of this, it passed over both to the environ of Autria (on account of the over both to the empire of Austria (on account of the inheritance of the dukedom of Burgundy) and to Spain, after the death of the celebrated Charles V. The order can be conferred both by the sovereigns of Austria and of Spain. The name evidently was derived from the classic legend of Jason and the Golden Fleece.

classic legend of Jason and the Golden Fleece.

FLRET, fleet (Sax. flota, fliet), the term applied to the different detachments, or squadrons, which form the navy of any country, which are stationed in various parts of the world, for defence, aggression, or intimidation. England has, for instance, her Channel fleet, her North-American fleet, and some others; as also liave the chief naval powers. In the more extended interpretation of the term, it is also applied to any company of vessels united together, and sniling with one object, either mercantile or warlike. (For further information, see separate article NAVY.)

FLEET MARNIAGES were certain irregular marriages which were very prevalent in England in the latter half of the 17th and the earlier half of the 18th centuries, and were so called from being celebrated in the Fleet prison. The persons who celebrated these marriages were clergymen of the Church of England, imprisoned for debt, who, having lost all sense of propriety, were willing thus to prosti-

lost all sense of propriety, were willing thus to prostitute their calling. Young ladies were compelled to tute their calling. I doing males were compened to marry against their wills, and young men were in-veigled into marriages with the most worthless characters,—while prolligates found it very convenient, as enabling them to enter into a union which they could dissolve at pleasure. The accounts of the number of dissolve at pleasure. The accounts of the number of marriages thus celebrated are almost incredible. Attempts were made to stop the practice by acts of parliament; but these were of no avail against persons who had nothing to lose. At length, however, this enormity was brought to a termination by 26 Geo. II. c. 33, which declared that marriages solemnized in o. 35, which declared that matriages sciennized in any piece other than a church or public chapel, and without due publication of the banns, or license obtained from a proper authority, were not only void, but subjected the person sciennizing them to felony, punishable by transportation for fourteen years. (See Marriage.)

First Passon, a celebrated London prison, pulled down in 1845, and so called from being situated on the down in 1920, and so called from being situated on the lime, and a small quantity of chloride of sodium.

There, is rapid stream which flowed into the fine the classification of the insect tribe, and the name by once at least as early as the 13th century, and to it which it is distinguished in this order is Mucca comistered from committed those who had incurred the displeasure of the Star Chamber. When that court domestica. The insect is termed fleat-fly, from the fact was abolished, it became a prison for debtors, and for

persons charged with contempt of the courts of Chancery, Exchequer, and Common Pleas. This prison was burned in the great fire of London, in 1686, and again during the Gordon riots, in 1780.

FLEMISH LANGUAGE AND LITERATURE, flem ish (Ger. Flämisch or Vlämisch).—The Flemish is the vernacular language of the Flemings, an ancient people vernacular language of the Flemings, an ancient people who inhabit certain parts of Belgium and Holland, and who number upwards of 2,000,000. It is a form of the low German, and the Dutch of the present day is a modern offshoot of it. It is more palastal and nasal than the language of Holland, which, on the other hand, is more guttural; but the differences are not essential. So little change has taken place in this language, that the earliest monuments of its literature, an ordinance of Duke Henry I. of Brabant (1229), is perfectly intelligible in the present day. Among the an ordinance of Duke Henry I. of Brabant (1229), is perfectly intelligible in the present day. Annon the more remarkable of the earliest works in this language are the Rymbybel, or Bible in rhyme; and the Spiegel autoricel, the Historical Mirror, of J. Van Meerlans (born in 1235); the Civic Laws of Antwerp (1300); the Chronicle of J. Van Clere, and many others; a translation of Boethius, by Jacob Velt, of Bruges, of the 15th century; and the "Hive of the Catholic Churck," by Philip Van Marnix (1569). Many French forms of speech were introduced during the Burgundian reign, and also many Dutch during the sway of the Hapsburge; so that the old Flemisk lost much of its purity and terseness. Hooft, Voudel, and Cats, are the three men whose names figure most prominently among the writers of the 17th century; but the 18th furnishes scarcely any name of note. Under Napoleon, every effort was made to suppress the use of this laneffort was made to suppress the use of this lan-guage and introduce the French; and it is only since the revolution of 1830 that the Flemish has again come to occupy its former position. Since that time numerous societies and unious have been formed, newsrous societies and unious have been formed, newspapers and periodicals published, and other means adopted, with a view to diffusing a knowledge and a taste for the cultivation of this language. Among the names of those who have most exerted themselves with this object, are Willems, Blommaert, Van Ryswyck, Conscience, Van de Voorde, Delecourt, Dantzenberg, Van Buyse, Snellaert, de Laet, Dedecker, David, and Bormann. The government was at first opposed to, or at least looked with coldness upon, this movement; but, latterly, it has come to recognize it and give it countenance. On the occasion of a linguistic concress at Ghent, in 1841, the members of a linguistic congress at Ghent, in 1841, the members of the government, for the first time, publicly addressed the people in the Flemish language. Besides the Flemish grammars of Van Beers and Heremans, and the dictionary of Sleecz, we may mention Vandenbossche, Nouvelle Grammaire raisonnée pour apprendre bossche, Nouvelle Grummaire raisonnée pour apprendre le Lannad et le hollandais, Lille, 1825; J. Desroches, Grummaire flamande, Antwerp, 1926; Vundenhoven, La Langue flamande, son passé et con avenir, Brussels, 1844; Lebrocquy, Analogies linguistiques; du flamand dans ses rapports avec les autres idiomes l'origine tentonique, Brussels, 1845; Desroches, Nouveau Dictionnaire français-flamand et flamand-français, Ghent, 1805; Olinger, Nouveau Dictionnaire françois-flamand, Malines, 1834.—See, also, Sleecx on the History and Relations of the Flemish to other Languages.

FLESS. Resh (Sax. flace). a commound aubstance.

FLESK, flesh (Sax. flee), a compound substance, constituting a large portion of every animal; consisting of the softer solids, as distinguished from the bones ing of the softer solids, as distinguished from the bones and finids. As a general appellation, it may be taken to include the blood-vessels, nerves, cellular tissue, &c. (See Muscha, Trissua.) Chemically considered, flesh consists of fibrin in a coagulated form, permeated by at least three times its weight of water and fluid, consisting partly of blood sad partly of substances secreted from it. The soluble matters consist obiefly also for the blood two animal of the blood two animals. secreted from it. The soluble matters consist onemy of albumen, the soluble saits of the blood, two animal principles, called kreatine and urorite, and phosphoric, lactic, butyric, acetic, and formic acids. The saits consist of the phosphate of potash, magnesis, and lime, and a small quantity of chloride of sodium.

FLESH-FLY belongs to the general order of Dipters in the land the name by

#### Fleta

larvæ are hatched. It is generally larger than the common house-fly, and its wings indeed are sometimes nearly three-quarters of an inch in expanse. It is dis tinguished by a proboscis, always very apparent, mem-branous, and bibliste, generally bearing two palpi, and capable of being withdrawn entirely within the ord cavity: it also has a stoker of two pieces; the antenna in a plate with lateral setm.

FLETA, flo'-tu, is the name of a valuable treatise, in FLETA, 160'-121 is the name of a variation creame, in Latin, on the law of England, and is so called from its having been written in the Fleet prison. Nothing is known of the author; but it must have been written about the thirteenth year of the reign of Edward I. It is one of the earliest authorities on English law, and gives a complete account of it as it stood at the

time the author wrote.

FLEUR-DE-LIS, flur-de-le' (Fr.), the heraldic term for the flower of the water-lily or yellow flag, which constituted the principal feature in the armorial bearconstituted the principal feature in the armorial bearings of the monarchs of France prior to the execution of Louis XVI. and the establishment of the first French republic. It was introduced into the arms of France about the year 1140, being first borne by Louis VII. This monarch, who had exercised regal power during the lifetime of his father, had probably adopted and worn it even prior to this date as his badge or cognizance, as the Plantagenets distinguished themselves by hearing a saving of brooms and from themselves by bearing a sprig of broom; and from this circumstance its present name may be derived, being a corruption of near de Loys, or flower of Louis. Some, however, believe it to be so called because it grew in great abundance on the banks of the Lys, a river rising in the north of France, and joining the Escaut near Ghent. It is used as an ornament of the crown of the English sovereign, and the regal insignia of many of the continental monarchs, and it forms, in Her., the mark of cadency for the sixth son.

FLEXIBILITY, fleks-e-bill-e-te (Lat. flectere, to bend), a property which all bodies possess to a greater or less degree, which is evinced in their disposition to yield or change their form in a direction at right augles to their length, through their own weight or by means of any pressure or strain applied to them. Pieces of the same material differ from each other in the degree of flexibility they exhibit, in proportion to their length and thickness. Thus it is evident that a cylindrical bar of iron an inch in diameter and twenty feet in length will exhibit a far greater degree of flexibility than another which is only half the length, and has a diameter of two inches. This may be seen by resting the extremities of each on supports of equal beight, when the long bar would become curved in form through its own weight, its centre being considerably below a chord drawn from one end of it to the other; while the thicker bar would be scarcely bent out of the straight line. Materials also exhibit a greater degree of flexibility in one condition than in another; metals, for instance, yielding far more readily another; metals, for instance, yielding far more readily to pressure when beated than when cold. A wroughtiron beam which would sustain a great weight without perceptible deflection when cold, would bend considerably under the same weight when red-hot. The great flexibility of ropes of hemp and metal renders it quite impossible to stretch them horizontally in a straight line, as may be seen in the case of a rope stretched for the performance of a tight-rope dancer. There is no material that will not exhibit flexibility in some degree, because there is no substance in nature that is perfectly rigid and inflexible; but the degree of flexibility possessed by any material is denoted by the extent to which it will bend, or by the weight which it will support without breaking. This property must not be confounded with that of elasticity; elastic bodies will return to their former shape when they have been bent or aftered by pressure in any way; but bodies which possess flexibility without elas-ticity do not return to their original form in all cases. A straight bar of iron, though bent by its own weight A straight bar of iron, though bent by its own weight, only, will not exactly resume its original shape, although a rope will do so. The consideration of the deflection or flexibility of beams of wood and iron bars and girders, as well as of ropes and chains, and other materials, is an important point in the construction of buildings, bridges, and engineering works of various kinds. (See MATRIALS, STRENGTH OF.)

## Floating Islands

FLEXOE, fick'-sor (Lat. fiecto, I bend), in Anat., is the name of certain muscles whose office it is to bend the parts into which they are inserted. The antago-nistic muscles are termed extensors.

FLINT, flint (Ang.-Sex.), in Min., the well-known silicious nodules and concretions occurring so abundantly in the chalk strata of England, and many other calcareous strats. Fints are composed almost entirely of silica, with traces of iron, clay, and lime. The formation of flint has long been a disputed question amongst geologists: the dialytic discoveries of Graham and Church throw great light on the matter. If a solution of silica be prepared by dialysis, and poured into a vessel containing a very minute quantity of carbonate of lime, the whole becomes rapidly pectised, assuming: the gelatinous form in a few minutes. From this it will be easily seen what would happen if a lake or river, containing a notable quantity of silica in solution, were to suddenly flood a chalk plateau. Flint is of great importance as an economic product, being largely used, when calcined and ground, in the manufacture of china. in the chalk strata of England, and many other calca when calcined and ground, in the manufacture of china, porcelain, and glass. In parts of the country where fints are plentiful, it is much used as a building material, with excellent artistic effect.

Film GLASS. (See GLASS.)

FLINT GLASS. (See GLASS.)

FLINT IMPLEMENTS AND WEAPONS are relies of the primitive inhabitants of Europe, which have been discovered from time to time, by being accidentally turned up whitst ploughing in fields, or by the sealous search of some indefatigable antiquarian. Those which have of some indefatigable antiquarian. Those which have already been discovered do not differ in the slightest respect from the rade weapons constructed of flint which are used even in the present day by the savages inhabiting portions of Asia, America, Africa, and the islands in the Indian Archipelago and the South Seas. Arrow-heads and hatchets are the forms in which the weapons are mostly discovered, and there is an nu-limited variety in the shape and construction of even these. Some capital specimens can be seen by the inquiring reader in the British Museum; and amongst them must be specially noted the flint implements which were found alongside the remains of an elephant in the year 1715, in Gray's-Inn Lane, London. Not long since geological students invested these flint implements and weapons with some considerable amount of interest, as they thought that by these means the date at which the larger classes of mammalia, such as elephants, &c., celled to exist in Europe, might be discovered. As yet (1862), however, their exertions have not met with nuch success, as it is nearly impossible to affix any assigned period at which these implements and weapons were commonly used. In the South of France, in Norway, and in England, these distant traces of our ancestors have been mostly discovered; and it is a fact that flint weapons were used by the Druids in England

long before the invasion of the Romans.

FLOATING. (See Swimming.)

FLOATING BATTERY, flote'ing bat'-te-re (Sax. flotan, to float), in nattical language, a term applied to a hulk which has been cut down and rendered as strong and shot-proof as possible, and in which are placed heavy cannon and mortars for the purpose of defending or attacking barbours and other maritime strongholds. This species of war-vessel was first used at the siege of Gibrsitar, in the years 1779—1783; and it was again brought into use during the Crimean war. On account of their clumsiness, and the difficulty of navigating them, floating batteries are, however, not much in

request at the present day.

FLOATING BRIDGE. (See FERRY-BRIDGE.)
FLOATING ISLANDS, GARDENS, AND HOUSES.—Gardens and islands, formed of patches of wood and weeds, covered with grass, flowers, and other vegetable productions, supported on the surface of the water. On the English lakes there are one or two of these natural eccentricities, and on the Ganges, in India, they natural eccentricities, and on the Gunges, in India, they are continually passing down the river, being detached from the banks by the force of the currents. On these latter, tall trees are often seen; and it presents a curious spectacle to observe these monarchs of the forest borne down by wind and tide on the bosom of the waters on some compact little island, which seems created for their especial sovereignty. In ancient mythology, the island of Delus, one of the Cyclades, was supposed to be endowed with floating powers, and to

955

#### Float-stone

be capable of sinking below the surface of the deep, and be capable of sinking below the surface of the deep, and rising again at various intervals, in some new spot. In northern India, and on the borders of Thibet and Persia, foating gardens are often erected by the natives, for the purpose of raising melons, encumbers, and other similar vegetables and plauts, which require a very equeous soil for their cultivation. These gardens, however, a property of the contraction of the contra ever, are of a very fragile nature, and rarely exceed a ever, are of a very fragile nature, and rarely exceed as foot in depth of soil, their prime structure being com-posed of wickerwork, interlaced with reeds and watlings, and severed with matting, over which the earth is placed. Floating houses are built by the inhabitants of Bangk'ck, the capital of Siam, from motives of comfort and safety. These houses form whole streets, being anchored in rows, and are capable of being moved from one position to another at pleasure. From the depth of water, large vessels of from 200 to 800 tons burden can sail up this picturesque town, and pass alongside the houses of the inhabitants. These floating houses are made of bamboo-stems, wickerwork, and palms, with a verandah in front; and they are built on large rafts. Sir John Bowring gives a capital account of them

in his sketch of Siam.

FLOAT-STONN, flote'-stone, in Min., a porous, soft, and frisble mineral, consisting of silica, alumins, and carbonate of lime. From containing numerous pores, it holds a large quantity of air, and swims on water until

holds a large quantity of air, and swims on water until it is saturated; hence its name.

FLOCOILATION, flok-sil-lai'-shun (Lat. floccitatio, from floccus, a lock of wool), in Med., is a term applied to the picking the bedelothes, which is sometimes observed in fever and other patients, and which is always regarded as a symptom of great danger.

FLODDEN FIELD, BATTLE OF, flod'-den, was for the Scots one of the most disastrous encounters that ever took place, between them and their southern focus

Scots one of the most disastrous encounters that ever took place between them and their southern foes. James IV. of Scotland, a warlike but rash king, crossed the Tweed at the head of a large army, on 22nd August, 1613. Henry VIII. was at the time in France; and the defence of the country fell to the earl of Surrey, who as quickly as possible assembled an armed force to meet the Scotch king. James, instead of at once taking decisive steps, lingered near the border, until, by desertion, his army was reduced to 30.000 men. On the 6th tion, his army was reduced to 30,000 men. On the 6th of September he encamped on Flodden, the last of the Cheviot hills, in Northumberland; and on the morning of the 9th, Surrey, by a skilful movement, took up a position between the Scotch and their own country. The battle commenced about 4 o'clock in the afternoon of the same day. The Scotch left wing, under the command of the earls of Huntly and Home, speedily put to flight the English right wing; but the High-landers on the right wing were unable to stand against the severe execution of the English archers; they rushed upon them in disorder, and were soon forced to flee. Meanwhile, the battle was raging with great fury nee. Meanwhile, the battle was raging with great tury between the two centres. James, surrounded by his nobles, charged upon Surrey with such force as to penetrate within a few yards of the royal standard, when he was at length cut down, and all his followers perished with their king. The loss of the Scots was about 10,000, including the flower of the nobility; while the loss of the English was only about 7,000, and mostly men of inferior note. "Scarce a family of eminence," men of inferior note. "Scarce a family of eminence," says Scott, "but had an ancestor killed at Flodden; and there is no province of Scotland, even at this day, where the battle is mentioned without a sensation of terror and sorrow." The last canto of Scott's "Marcontains an accurate and animated description of the battle of Flodden.

FLOGGING, flog-ging (Ang.-Sax.), a term generally used instead of the more correct appellation of corporal punishment. Flogging is a degrading system, which has exploded from our code of punishments (except in cases of boys or youths convicted of misde-(except in cases of boys or youths convicted in inde-meanor), and it is only kept up in the army and navy; in both of which services, however, it has but a very feeble footing. Until within the last few years, the punishment of flogging, usually administered with "a cat-o'-nine-tails," used to be one of the most horrible catto mine-tails, used to be one of the most norrhiel features in our service; but it is now, happily, nearly banished. Except in the most extreme cases, it is seldom resorted to, and a man has every chance of avoiding it, being obliged to repeat the same offence, which must be disgraceful, twice before being liable

#### Floor-cloth

to the "cat." In the middle ages, flogging used to be one of the most favourite methods of punishment, and criminals were often whipped through the town or towns on conviction of the most trifling offence.

FLOOD. (See DELUGE.)

FLOOD-CLOTH, flore kloth (Sax. flor, floor), strong canvas woven from yarns made of hemp and flax combined, the surface of which is coated with paint, in order to render it a stout, solid, and durable covering order to render it a stont, sold, and durance overing for the floors of passages, entrance-balls, staircases, &c. The canvas used for this purpose is made in pieces about 100 yards long, and varying from 18 to 24 feet in width. This is done to obviate the necessity of joining narrow slips of canvas to form wider pieces, in which the seams would produce an unsightly appearance, and be attended with inconvenience when laid down, on account of the extra thickness of the floor-cloth in those parts where the lengths had been sewn together. For narrow floor-cloths for stairs and passages, the broad webs are cut to the width required. The following in the process word in the process with the pr orosa wees are cut to the width required. The following is the process used in the manufacture of this material:—The canvas is first cut into pieces of the required length and breadth, and the edges are fastened to the four sides of a large frame, which are then drawn apart by machinery, to stretch the canvas as tightly as possible, somewhat in the manner adopted in straining cauvas for Berlin-wool work. The position of the frame is vertical, the height being equal to the width of the canvas: when this exceeds six or eight feet, the upper part is reached by means of light scaffolds or sta which the workmen can move from one end of the piece to the other throughout the entire length, whenever occasion may require it during the process of painting. The canvas is then in a proper condition for the reception of the size and paint, which is iaid on to a tion of the size and paint, which is iaid on to a tion of the undergo the final process of printing. It is first coated with strong size on both sides, and while this still damp, the canvas is rubbed all over with pumices the size is still damp, the canvas is rubbed all over with pumices. stone, to render it smooth and even. When the size is dry, the canvas receives two coats of paint on each side. The first coat is very thick, being more like mortar than paint; it is laid on in lumps and patches, and smoothed all over the web with a broad flat trowel, in a manuer resembling that in which plaster is laid on a wall. When this is thoroughly dry, the surface is again rubbed with pumice-stone, and a second coat of thinner paint is laid on with a brush. The under side of the canvas requires activing rount to be down to it ofter this but the uncernothing more to be done to it after this, but the upper side receives two or three more coats of thin paint, being rubbed with pumice-stone after each coat has been laid on, in order to produce a smooth surface to receive the printed pattern. The canvas is now re-moved from the frame and wound round a roller, from which it is allowed to pass over a flat table, to receive the impression of the blocks. Formerly the patterns were stencilled, as the walls of rooms were before paperhangings were introduced; that is to say, they were produced by putting colouring matter on the surface, through holes and lines punched in a sheet of tin or pasteboard, so as to form the design required; but now the printing is effected by blocks, a separate block being required for every colour introduced into the pattern. The blocks are about fifteen inches square, and are made of deal, faced with wood of a fine close grain, with a handle at the back; that part of the pattern which each block is required to imprint on the canvas is left on its surface in relief, the remaining part being cut away, as in a wood-engraving. The surface of the projecting por-tion of each block is further cut into small squares, technically called teeth, by narrow grooves crossing each other at right angles. This is done to effect an technically called the growth of the same and other at right angles. This is done to effect an equal distribution of the paint, as if the surface of the projecting part of the blocks were left smooth and even, it would take up the colouring matter unevenly, and transfer it to the floor-cloth in irregular patches. The impression is effected by applying the surface of the block to a pad or cushion charged with the colour required; after which it is transferred to the floor-cloth by means of the handle at the back, and pressed forcibly by means of the handle at the back, and pressed foreign upon it. It is then removed, charged again with colour, and pressed on the canvas close by the side of the first impression, points being placed at the corners of the blocks to insure the regularity of the joining of the pattern. This process is repeated until the whole of the floor-cloth has been covered with that part of the

pattern which is imprinted by the first block that is used, after which the blocks intended to convey the remaining colours to its surface are used in a similar manner, until the pattern is complete. It must then manner, until the pattern is complete. It must keen be allowed to dry, care being taken to give the colouring matter sufficient time to harden thoroughly before the floor-cloth is taken into use. The borders along the sides of narrow pieces of floor-cloth intended for passages, are produced in the same manner, by blocks of the recessary width similarly morared for the of the necessary width, similarly prepared for the purpose. It should be stated that worn-out Brussels carpets afford a good foundation for floor-cloth, and may be converted into that material at any floor-cloth may be converted into that material at any floor-cloth manufactory. A cheap and durable covering may be made at home for passages, and even for rooms, by a method suggested by Mr. Loudon, in his "Encyclopedia of Cottage and Villa Architecture." For the former, a single length of strong unbleached calico will be required for the ground-work or foundation of the material; but for the latter, the lengths of calico must be joined together, until a piece has been produced of sufficient breadth to cover the room for which it is required. New salico, however, is not absolutely required. required. New calico, however, is not absolutely requi-site, as any pieces of calico or linen that are useless for any other purpose will do quite as well for the basis of the floor-cloth, after they have been neatly joined together. The calico must first be stretched on the floor by tacks, or by pasting down the edges to the boards, after which it must be covered with two or three coats of stout waste paper or newspaper, pasted together with a strong paste, to which a little alum has been added while boiling. Over this a layer of paper past of the walls of rooms must be pasted, which has used for the walls of rooms must be pasted, which may be laid on in lengths, or formed of separate pieces put together, to furnish a design suggested by the taste of together, to furnish a design suggested by the taste of the maker. When dry, the floor-cloth must be first painted over with a coat of strong size, next with two coats of boiled linseed oil, and lastly with copal varnish. Floor-cloths made in this manner are strong and inexpensive, and may be washed as well as those that have been made in the ordinary way. A cheap kind of floor-cloth has been lately introduced for the protection of carpets and stair carpets, somewhat similar to oil-baize, or oil-cloth for table-covers. It is made on a foundation of thin calico, and thinly coated with paint on one side only, after which the pattern is imprinted in the usual way, or by rollers.

way, or by rollers.

FLOORS, FLOORING, flores, flore'-ing, the name given to the stages or platforms which separate the successive stories of a building, from which the stories themselves are generally named in their order; as ground flore flores flores are generally named in their order; as ground flores flo floor, first-floor, second-floor, &c. In the large and lofty houses that are to be seen in Edinburgh, which are copied from those of continental cities, the floors are termed flats, and are let out to the tenants as comare termed lists, and sre let out to the tenants as complete and separate dwellings. The entire platform which separates any room from another, above or below it, consists of three distinct portions,—the joists, the flooring of the room above, and the ceiling of the room below. The joists are narrow beams of timber about 24 inches in thickness, and varying in depth according to the extent of span from wall to wall. As the walls of the successive stories are raised to the proper height, the joists are laid across about fifteen or eighteen inches apart, and the ends are imbedded in the masonry. In building a row of houses, care should be taken to keep nine inches at least of masonry between the code of the joists bridging the space from party-wall to party-wall, to prevent them from communicating the flames from one house to another by reason of their contiguity, should a fire break out in any one of them. To give greater stiffness and steadiness to the joists, they are often connected by short cross-struts of timber nailed transversely to the sides of the joists and across each other in the form of the latter X, at intervals of two or three feet. The ceiling is made by nailing laths across the bottom of the joists and covering them with two or three coatings of plaster. (See PLASTREINE.) The flooring consists of red or yellow deal planks about nine or eleven inches in width. The boards are laid transversely on the joists, and

laying down and nailing the boards. When a very close floor is required, the planks are generally jointed together by means of agroove and tongue. (See Journary.) The thickness of the boards varies from one to 14 inch. After the planks have been nailed to the joints, the brads are driven below the surface with a punch, and the edges of the boards are planed, that any inequalities may be removed and the whole extent any inequalities may be removed and the whole extent of flooring rendered perfectly level. The kind of floor that has just been described is termed a single-joisted floor. and is that which is usually found in buildness of floor in the thing is the twich is usually found in buildness of floor, and is that which is usually found in buildings of an ordinary character, where the span from wall to wall does not exceed twenty-four or twenty-five feet. In does not except twenty-nour or enemy-nive area. In small houses, the joists over a span of this extent are often rendered more steady by allowing them to bear on the framed partition between rooms below them, or on the semi-partitions on either side of folding-doors.
When the span exceeds this length, and the platforms are intended to support any great weight, as in a concertroom, assembly rooms, or warehouse, framed floors are adopted, in which wrought-iron girders are introduced.

FLORALIA, flo-rai'-le-ii (Lat.), a festival which, in ancient Rome, used to be celebrated in honour of Flora, the goddess of flowers. These ludi florales, according to Pliny, were instituted, by order of an oracle of the Sibyls, on the 28th April, 238 B.C., and, after having been discontinued, were re-established in alter naving been discontinued, were re-established in 173 B.C. They were principally celebrated during the night-time in the patrician quarter; but some authorities allege that they were held in a circus erected on the hill Hortulorum.

FLORICULTURE. (See HORTICULTURE.)

FLORICAL, floridus, flowery), in Bot., a term applied by some writers to the sub-class Petaleidæ (which see).

FLORICAL REGINER (See PERPREDICULTE ENGLISE)

FLORID ENGLISH. (See PERFENDICULAR ENGLISH.)
FLORID ENGLISH. (See PERFENDICULAR ENGLISH.)
FLORIN, flor'-in (Fr.), a name now applied to a
two-shilling piece in England, but which was formerly
a gold coin, circulated in Italy during the 18th century.
Its name is supposed to be derived from the fact of its being struck at Florence, or from a flower (lily) being imprinted on its reverse. A coin of Austria and Germany is also called a florin; but it is not of the stan-

many is also called a florin; but it is not of the standard of the English one, as its value varies from two shillings to one-and-eightpence.

FLORINIAES, flor-in'-ylns, a sect of Gnostics of the Zisi century, who were so called after Florinus, a Romish priest, and who inclined to the views of the Yelentinians. They maintained that light and darkvesterinam.

ness were two eternal principles, from which, respectively, all the good and evil in the universe had proceeded. (See GNOSTICISM.)

FLOSS SILK is carded like wool or cotton, and subse-

quently spun into a coarse thread or yarn for the manufacture of shawls, socks, or other common silk manufacture of snawls, socks, or other common slik fabrics. Floss silk is that portion of ravelled silk which is broken off in winding off the cocoons. In preparing it, it is first steeped in water, after which the gummy matter contained in it is pressed out. Upon being dried, a small quantity of oil is worked into it to render it more plant. Subsequently it is carded, and then spun. At the present day, superb fabrics of this material are produced in France, as

also in this country.

FLOYILLA, flo-til'-lit (Rp.), signifies, properly, a little fleet; and though sometimes used in this sense, it is more frequenty applied to a fleet of whatever size, composed only of small ressels. In this latter cense, the term was applied to that immense naral armament with which Napoleon meditated the invasion of

Britain.

FLOTSIM, flot'-sum (floating), is a law term, generally used in connection with the equally uncouth and barbarous terms jetsam and ligan, and applied to the goods of a vessel wrecked at sea. Flotsam is applied to such of the goods as continue floating on the surface of the waves; jetsam is where they are cast into the sea, and there sink and remain under water; and ligan, is where they are sunk in the sea, but tied to a cork or buoy in order to be found again. If no owner secured to them by long floor-brads, after having been appears to claim them within a year and a day, they pressed tightly together by the action of a screw that can be attached to the joists in the position required, and at any part, like a vice, during the process of things flotsam, jetsam, and ligan will not pass.

#### Flounder

FLOUNDER, flown'-der (Swed. flundra), (Pleuronectes flexus), a flat flah very simi-

PLOUNDERS.

to the plaice, but smaller, and of more obscure It is colour. very common about the British coast, and is found in the Northern, Bal-tic, and Mediterranean seas.

Ita body is co-

vered with very small scales, and along its back runs a row of sharp spines. FLOUR, flowr (originally flower, Fr. fleur), the finely

ground meal of wheat, and of any other corn or cereatic which has been reduced to powder in a mill. (See FLOUR-MILLS.) The component parts of flour are starch, gluten, sugar, gum, bran, and water, the prime element being starch. No substance is more adulterated than wheat-flour; and there are several modes of detection, the best of which is the specific-gravity test, as a vessel which contains one pound of wheat-flour will contain nearly a pound and a half of any other. Some chemical tests are also extremely good. Firstly, nitrio acid, which has the effect of colouring wheatnitric acid, which has the effect of colouring wheat-flour of a fine orange-yellow, while it does not affect the colour of fecula or starch; secondly, muriatic acid colours bond fide wheat-flour of a deep violet, but dissolves fecula and starch into a light viscous fluid, which is decomposable by the admixture of any alkali. Another test is the amount of ash left after the sample being burnt. Wheat-flour yields on the average 0.8 per cent. vereflour 1.0; hear, and nearmenl 3; and

per cent.; rye-flour, 10; bean, and pea-meal, 3; and linesed-meal, 10 per cent. of ash, by which means adulteration can be detected.—Ref. Ure's Dictionary.

FLOUR-MILLE, mills used for the purpose of grinding flour. Before the invention of the steam-engine, the windmill was principally used for this purpose. (See the article on WINDMILL for the details of its mechanism. anism.) In modern times, great improvements have been made in the machinery employed in grinding flour. In the ordinary method there are two circular stones used, each being about 4½ feet in diameter. They are in the form of flat discs, the lower one being fixed in a level position, while the upper one revolves horizontally on a vertical axis, with a speed of 100 to 120 revolutions per minute. Millstones are made of normalization of vertices axis, with a special of the 120 revolutions per minute. Millstones are made of various substances; but those in general use for grinding wheat are made of a very hard silicious stone imported from France, the technical name for which is burn or bukn. This stone is so porous that it sometimes requires to be filled up in parts with a composition of alum and grit; and yet it is so hard that a pair of stones in full work will last for twenty or thirty years. The surfaces of the stones are channelled or grooved. On account of the friction and the velocity of the upper stone, much heat is generated in grinding; and the flour thus produced is overground, and apt to clog into thus produced is overground, and app to corg muo humps. In order to avoid this, many plans have been invented of late years. Among these may be men-tioned that of Bovill, in which two ranges of millstones are driven by one central shaft. It is distinguished by an arrangement by which the meal or flour is dried by means of steam and hot air,-a method by which the manufactured flour, often in too dry a state after grinding, is moistened by steam; an arrangement for washing, is moistened by steam; an arrangement for washing grain and then drying by means of hot air; and lastly a contrivance by which the passage of the ground flour is facilitated. In Westrupp's conical mill there is a conical revolving stone beneath the upper stone, which is fixed. The upper stone is a hellow cone, and the lower stone fits into it. This kind of flour-mill grinds the wheat more completely than an ordinary mill, as the flour comes away from the stones more easily, and leaves less faring in the bran. In Schiele's mill a concare revolving surface multage and the stones more carried surface are the assint a convex thad surface. This is done in order to avoid the friction which re-sults from the contact of conical surfaces. Besides those mentioned, there have been improvements the produced into the mechanism of flour-mills by in its turn, and is displaced by a rush of cooler air; and

## Flue

Corcoran, Gordon, Taylor, Pinel, M'Lellan, Banks, Geodier, Spiller, Valok, Seeley, Harwood, White, and others. During the Orimean war, an important experiment was made by the English government. Two steambests were despatched, one fitted up with apparatus for the purpose of grinding flour, and the other for baking. The mill was found to be capable of grinding twenty bushels of flour per hour, even when the vessel was going at the rate of seven or eight knots an hour. When the steamers arrived at Balaclava, the mill was able to grind 24,000 lbs. of flour per day. Flour-mills have recently been made on a very extensive scale. In one mill near Blackfriars Bridge there are upwards of thirty pairs of millstones. thirty pairs of millstones.

FLOWER, flow'er (Fr. fieur), in Bot., that portion of a plant which is formed by the union of all the organs which contribute to the formation of the seed. In which contribute to the formation of the seed. In common language, the word is used to convey the idea of the portion in which the gavest colours are found. A complete flower consists of the essential organs of reproduction, inclosed in two particular envelopes which protect them. These essential organs are called the pistil and stamens. The floral surelopes are termed calvar and corolla. The extremity of the peduncle, or pedicel upon which the parts of the flower are placed, is called the thalamus or receptuals. (See the italicised words.) words.)

FLOWERING PLANTS. (See PHANNEOGAMIA.)
FLOWERLESS PLANTS. (See CHYPTOGAMIA.)
FLOWERS, ARTIFICIAL. (See ARTIFICIAL FLOWERS.)
FLOWERS, COLOURING MATTERS OF.—Fremy and Cloez consider that the colouring matters of flowers may be divided into cyanine, or blue, which, with different portions of aoid, forms purples and reds, and yellow, or manhine, which, with alkaline juices, gives different shades of yellow and brown.

Flowers, Linguage of. (See Linguage of

FLOWERS.)

FLOWERS.)

FLUE, flu (probably from Lat. flumen), a narrow passage in the wall of a house, running from the bottom to the top, and constructed to carry off the smoke that arises from burning any kind of fuel in a grate or stove. The expression may be considered as being almost synonymous with the term chimney, although it is more particularly applied to that part of the passage which is between the gathering or funnel of the chimney (see Fireplace), at the base, and the upper extremity of the chimney-shaft, which generally rises for some distance above the roof. The part in which a junction is formed between the gathering and the flue is called the throat of the latter. When a number of flues are unit close together in a party-wall between of flues are cuilt close together in a party-wall between two houses, or in the gable-ends of a single house, the wall itself is called a stack, or chimney-stack; and the wall isser is cause a stack, or chimney-shaft. The walls which separate flues built side by side in a stack are called withs, the walls which form their front and back being named the breast and back respectively. The horizontal section of a flue is generally oval or circular in form when the wall is built of stone, and rectangular when it is of brick. When flues are built side by side in the partywall of two houses consisting of three or more stories, that which rises from each fireplace is constructed to pass upwards through the wall on one side of the flue which is connected with the fireplace in the room immediately above. Chimneys in party-walls, conse-quently, assume a winding form; but all turns in a chimney should be gradually curved, care being taken to avoid angles, which afford convenient places for the accumulation of soot, and impede the free passage of the sweeping-machine through the flue. In addition the sweeping-machine through the flue. In addition to this, angular turnings in flues frequently lessen the free draught of air that is necessary to carry off the smoke of the burning fuel below, and thus offer an obstruction to its ascent which cannot be readily removed. The cause of the ascent of smoke in a chimney is simply this:—the fire burning in the grate heats the air in the flue, and causes it to become much lighter than the cooler air that fills the apartment with

this process being continually and rapidly repeated, an upward current of air is produced, which carries off the smoke and vapour arising from the combustion of the fuel below. To prevent a chimney from smoking, it is necessary to let the fine be as high and as straight as it possibly can be; since the draught will be greater in proportion to the height of the chimney and the absence of all interior obstructions in the shape of elbows or angular turnings. In the next place, the opening of the fireplace and the threat of the chimney should be as small as they conveniently can be, that the greater part of the accending air may pass through the fire prior to its ascent, and that the contraction of the chimney may cause it to rush through the narrow vent formed for its escape with greater force. The expediency of reducing the opening of the fireplace as far as appearance will admit, may be shown by holding a newspaper before the orifice above the cavity which contains the fire. This will cause the fire to "draw instantaneously, and break into a blaze; an effect ap" instantaneously, and preak into a plaze; an enec which is produced solely by lessening the opening by which air is admitted into the chimney, and thereby causing the air itself to pass through the fire before it makes its way into the flue. If a chimney be constructed under the conditions above mentioned, it will very rarely be found to smoke; and even amoky chimneys may be cured by having recourse to these precautions, and by removing any obstacle that may exist in the interior to the free passage of the air and smoke. Even downward currents of sir, which frequently cause a chimney to smoke when it is surrounded by buildings as high or higher than itself, may be prevented from causing any serious annoyance by the adoption of these means. To prevent the entrance of sudden gusts and eddies of wind, the chimney-pots, which are almost always placed on the chimney-shafts to contract the space through which the smoke escapes into the open air, are generally surmounted with a revolving cap or cowl made of metal, which is constructed in such a manner that it is turned by the wind like a vane, and constantly presents the orifice through which the amoke issues to that quarter which happens to be exactly opposite to the point from which the wind is blowing.—Ref. Count Rumford's Essays, Political, Economical, and Philosophical.

FLUID, flu'-id (Lat. fluidus, from fluo, I flow), is defined to be that whose component parts or particles yield to the slightest pressure, and are moved or disseminated amongst each other without any apparent sensible resistance. Some writers on scientific subjects distinguish between fluids and liquids. All liquids are fluids; but it does not necessarily follow that all fluids are liquids: for air, ether, mercury, water, and alcohol, are all fluids; but water and alcohol are also liquids. because they wet, or create moisture on bodies, which meronry and air do not do. Fluids are of two disneronry and air do not do. Fibrals are of two dis-tinctive kinds,—elastic and non-elastic; the former are comprised under the general term Pueumatics, and include all airs and gases; while the latter, which only include water and other aqueous fluids, are comprised under the general head of Hydrostatics and Hydrau-The terms elastic and non-elastic are only used here in a relative sense, and not absolutely, as all fluids are clastic more or less, water being compressible, although offering resistance.

ible, although onering remandance.

FLUGERSCENT RAYS, fin-o-res'-ent rais, certain rays
which exist beyond the blue end of the spectrum, inwishle under certain circumstances. If the prismatic spectrum be interrupted by a bath of esculin or sulphate of quinine, it will appear to be elongated at the blue end. The fluorescent rays are those which have the greatest actinic influence

(See HYDROFLUORIC FLUORIC ACID, flu-or'-ik.

FLUGRINE, flut-o-rine (in Chem.), symbol F, equiva-lent 19, supposed density 1.31, combining volume 2. Many unsuccessful attempts have been made to isolate this body. Several chemists have succeeded in ob-taining an impure form of it by using vessels of fluor spar, but its properties have nover been satisfactorily determined. Its compounds, however, so closely determined. Its compounds, however, so closely resemble those of chlorine, that but little doubt is resemble those of chlorine, that but little doubt is equi-soncest flute, &c.
entertained as to its being very similar to that body is its leading characteristics. Its principal compounds its leading characteristics. Its principal compounds is applied to any prefernatural fluid evacuation from are fluoride of calcium, or fluor spar, and hydrofluoric the body, but moss especially to those that proceed

scid (which see). It also combines with mest of the metals; also with boron, silicon, sulphur, silenium, and phosphorus. It exhibits no tendency to unite with oxygen. It is found somewhat sparingly in the mineral kingdom, in fluor spar, epatite, topaz, and a few other minerals. It also exists in the ashes of sea-plants, in sea-water, and in blood, milk, and the human teeth. with boron and silicon it forms two compounds, which are absorbed by water, giving rise, respectively, to fluoboric and fluosilicic acids.

FLUOR SPAR, flu-or spar, in Min., a mineral of great beauty, found in different parts of the world, but principally at Castleton, in Derbyshire, and Aston Moor, in Cumberland. It occurs in cubes and octahedra and concretionary masses, being most commonly of a violet-blue colour, but also yellow, green, purplish-red, and red. In its rougher forms it is often used as a flux, and the finer specimens are fashioned into cups and vases, under the name of Derbyshire spar. It consists.

chemically, of fluoride of calcium.

FLUTE, flute (Fr.), a popular musical instrument, themse of which, under various forms, may be traced to the most remote ages. Of its origin no direct account can be given : by the ancient poets, its invention was ascribed to gods and goddesses. Lucretius tells us that it derived its origin "from the breathing of the western winds over certain reeds." The sounds thus produced, he imagines, gave rise to the rural pipe, which, after undergoing many changes, has, by the ingenuity of later ages, been developed into one of the most clegant and fascinating instruments of which musical science can boast. In its primitive state, the flute was played like the modern flageolet, with a mouth-piece at the upper end; and from the shape of this mouth-piece, which resembled the beak of a bird, it received the name of \*hute a bec. In this form, with slight alterations, it continued until the beginning of the last century, when it was gradually superseded by the flauto traverse, or transverse flute, so called from its being blown at the side, and consequently held in a horizontal position. At its introduction, this instrument was about eighteen inches in length, and had but one key: even in this state it was a great improvement on the old flute à bec. Shortly after, a movable head-joint was invented, its length being increased, and more keys added; some flutes at the present time having more than a dozen keys, and few less than six. By means of these, they are enabled to execute any music, however chromatic, if within their compass, which extends from C below the treble to C in altissimo. Some few will go four notes lower, and au experienced player will reach E flat in altissimo. In December, 1832, a flute of an entirely new construc-tion was invented by Mr. Boehm of Munich: it however remained in obscurity until 1837, when it was adopted and introduced to the French professors by Mr. Camus; but they considered its adoption would be attended with too much trouble, in consequence of its having an open G sharp key. This, however, was be attended with too much trouble, in consequence of its having an open G sharp key. This, however, was soon after remedied by Mr. Dorus, who put a shaf G sharp key in its place. It now became universally adopted, and having, in its altered state, received the approval of the Royal Academy of Fine Arts in Paris, has been thoroughly established in France ever since. This instrument was first introduced to English players in 1841 by Mr. Clinton, who claims for it the following advantages: "perfection of tone," because every aperture is in its proper and ustural position: "equality of ture is in its proper and natural position; "equality of tone," because the holes are equal in size and distance; "superior quality of tone," because the bore of the instrument is not sacrificed to a false arrangement and size of the finger-holes; and "greater susceptibility of sweches," because every note is enlarged to the most available extent consistent with purity of sound. In the International Exhibition for 1862, Messra. Clinton & Co. exhibited a curious collection of flutes, showing the progress made in the manufacture of this instrument from the earliest times: they also exhibited an improved eight-keyed flute of their own construction, with new key mechanism, designed for tropical climates; as well as one which is termed the

Fly

from the bowels. It is frequently applied to diarrhose and dysentery was long known as the bloody flux. (See Diarrhose, Dysenvers.)
Fiuxes, fate'-ex, in Chem.—Fluxes are those compounds which are used by the chemist either as aids to

FLUXES, \*\*fakt'-ax\*, in Chem.—Fluxes are those compounds which are used by the chemist either as aids to the fusion of bodies, or as reducing or oxidizing agents. Fluxes may be divided into four classes,—reducing, oxidizing, double decomposing, and simple fluxes. The most important reducing fluxes are the carbonates of soda and ipotash, used alone or mixed with charcoal; cyanide of potassium, and black flux, a compound formed by throwing into a red-hot crucible a mixture of two parts of cream of tartar and one of water. The nitrates of potash and soda are the principal oxidizing fluxes, and a mixture of three parts carbonate of soda and four of carbonate of potash forms an excellent double decomposing flux. The simple fluxes act as purifying agents, removing and dissolving any mechanical impurity contained in the substance soted upon. Borax, microcosule salt, and powdered glass, are used as simple fluxes. The limestone used

any mechanical impurity contained in the substance sorted upon. Borax, microcosmic salt, and powdered glass, are used as simple fluxes. The limestone used in iron-smelting is a good example of a flux.

Fluxinous, full-shaus (from Lat. fluo, I flow).—The more common appellations by which the theory of fluxinous is known to the garrent reader or market. fluxions is known to the general reader or mathe-matical student, are the differential or integral calculus. The calculus of fluxions, which is one of the most important additions ever made to the abstract mathematical sciences, was invented about the middle of the 17th century. By the use of fluxions as an instrument of analysis, the science of geometry has been greatly enlarged; it has further rendered most efficient and incalculable aid in the investigation of the guiding principles of nature, more especially in establishing true theories of the definite motions of the stars and other heavenly bodies: astronomy without this theory would never have attained its present high position in the scale of human knowledge. In the beginning of the 17th century, the writings of Archimedes, and the works of the ancients on abstract science, greatly engaged the attention of the principal students of mathematics; the result was, that they thoroughly laid open the principles of Archimedes, which far surpassed those of the other ancient writers on this surpassed those of the other ancient writers on this subject. The celebrated Kepler greatly extended the theory propounded by the ancient philosopher, and the idea of fluxions became apparent, as Archimedes' theorems were of too limited a description to satisfy so bold an investigator. The theory of fluxions, or calculation of the velocity in uniform or variable motion, necessarily depends on that higher system of trigonometry which treats on drawing tangents to curves. The facility which this new portion of relegitive ages to the extension of geometry. notion of velocity gave to the extension of geometry, induced various foreign mathematicians, as Descartes, Roberval, and Fermat, to employ it in their researches. So very near did the last-mentioned approach to the true theory of the fluxional or differential calculus, that Laplace says he ought to be reputed its inventor. To find the real discoverer, however, we must look to two men, Newton and Leibnitz, who both claim the honour of its invention. The candidateship for that honour led to such a fierce discussion, that one need not be surprised at the high position which mathematical discoveries take; but from all the contingent circumstances of the case, and from Nowton having promulated and published his method the first, which he did in the year 1665, we will not err in laying the authorship of this system to him. The principles of Newton's theory may be thus described:—1. Supposing two quantities to have a given relation to each other (for example, the one to be always equal to the square of the other), and the rate of increase of one of them at any instant of time to be known; to find the rate of increase of the other at the same instant. These rates of increase were called the fluxions of its quantities; and the rules for their determination constituted the direct method of fluxions. or differential calculus. 2. The discoveries take; but from all the contingent circumand the rules for their determination constituted the direct method of fuzzions, or differential calculus. 2. The second part of this theory was exactly the reverse of the first; it is a problem in which the relations between the rates of increase of two quantities, which depended the one on the other, being given, it was required to discover the relation of the quantities. This was the inverse method, or integral calculus. In the application of algebra to the theory of curves, or curve lines, some

of the quantities under consideration are conceived as of the quantities under consideration are conceived as having always the same magnitude, as, for instance, the parameter of a parabola, and the axes of an ellipse or hyperbols; others again are indefinite in respect of negnitude, and may have any number of particular values; such are the co-ordinates at any point in a curve. This difference in the nature of the quantities has equally place in various theories of pure and mixed mathematics, and it naturally suggests the division of all quantities into two kinds; namely, such as are constant and such as are variable. A constant quantity always retains its same value, while a variable quantity varies its magnitude and value. These definitions have to be well remembered in working out the theories of the calculus of fluxions. According to theories of the calculus of fluxions. According to Newton's theory, a plane, curve, or line, may be con-ceived as generated by a point moving uniformly in the direction of some fixed line, and having at the same time a lateral motion with respect to this line, which is governed by some law dependent upon the nature of the curve generated. The part of the curve which is generated at any instant of time is called the fluent, and that infinitely small element generated during the next infinitely small and constant period of time is called its fluxion. If, in addition to the two motions already explained, we conceive the point to have a third motion at right angles to the plane of the other two, and also regulated by a law which must depend upon the nature of the curve, the generating point will describe a curve in space, which may be either a plane-curre, or one of double curvature. It may be thus easily surmised that by suitably regulating the laws of motion of the gene-rating point, any curve whatever may be described; it is also obvious from the theorem laid down, that, by the law of relation between the fluxions of the elements. the nature of the curve may be easily discovered. In the general deductions of mathematical science, if we the general deductions of mathematical science, if we suppose any line, which may vary according to some law, to move according to any fixed law, it will generate a surface, and the portion generated during any infinitely small portion of time will be the fluxion of the surface, while the whole portion generated will be the fluent. In a consequent manner, if a plain area move in any direction, the area being supposed to vary by a fixed have then will the infinitely amen value accounted in law, then will the infinitely small volume generated in an infinitely small portion of time be the fluxion of the solid, and the portion generated will be the fluent. In this system, any magnitude may be regarded as flowing ultimately from a point; a point in its motion may generate any into; a line in its motion may be made to generate any surface; and, lastly, a surface may generate any volume. It may be well said that the system of fluents and fluxions developed great credit on its inventor, as it is exceedingly ingenious, and has no superior in conveying an idea of the operations of calculus. The methods of integral and differential calculus, however, which are less complex and more calculus, however, which are less complex and more trustworthy, have now superseded them, although they are still employed in working out some problems. The notation of fluxions has been found to be their drawn that the still represent the still representation of the still represen back, and this is the main superiority of differentials and integrals over them. In conclusion, it may be stated, that the great facility which the theory of infinitesimals that the great menty which the theory of infinitesimals in fluxions gives to the applications of the calculus in the higher branches of geometry, and more especially to the doctrines of physics, is a high recommendation in its favour, and will be one of the strongest reasons for including the system of fluxions in the ranks of working mathematical theorems.

working mathematical theorems.

FLY, fit (Sax. fleoge), a name applied almost indiscriminately to all insects possessing wings; by many, however, restricted to the various species of dipterous insects. The fly is obsaracterized as possessing a pair of veined and membranous wings, with two movable bodies called balancers (kalteres), placed a little behind them. The mouth is formed of between two and six setaceous pieces of scaly texture, and these pieces are either inclosed in a prohoscis-like sheath, or covered by one or two lamina, which form it. The head is globular or hemispherical. The mouth is only formed for transmitting fluids, and is consequently very delicate in structure. The sucker performs the part of a lancet, and pierces the envelope of regetable or animal fluids, in order to allow of the fluid itself being transmitted up into the mouth of the insect. The antenne

## Fly-catchers

are united in front, and are approximate at the base. Above the true wings of the insect, and a little behind them, are the balancers, or halterer: these are almost membracous, and are furnished with two little knobs at their extremities, which are capable of dilation. The legs of this class of insects are long and slender; and the feet, it is well known, are furnished with skinny palms, to enable them to stick on glass and other smooth bodies by means of the pressure of the

atmosphere.

FLY-OATCHERS, fli-kātah erz (Muscicapidæ). — This very numerous family is widely diffused throughout both the eastern and western continents. As their name implies, they prey on insects, which they seize in name implies, they prey on insects, which they seize in mid-sir. They have the beak horizontally depressed, and armed with bristles at its base, with the point more or less decurved and emarginated. The value of the insectivorous family of birds to man is inosiculable. As Buffon truly says, "Vain would be the efforts of man to destroy or banish the clouds of flying insects by which he would be assailed. Man and quadrupeds cannot defend themselves against them. They attack with their stings; they oppose the progress of sulfiwith their stings; they oppose the progress of cultivation, and devour the useful productions of the earth. They infect with their excrement, or their eggs, all the provisions which are necessary to be preserved. Thus we find that the beneficent birds are not even sufficiently numerous in such climates, where, nevertheless, their species are by far the most multiplied." tuer species are by far the most multiplied." One of the best types of fly-catchers is that presented by the tyrant fly-catcher (Muscicapa Tyrannus, Briss.). This bird is peculiar to America. It is eight inches in length, and fourteen in extent of wing. The general colour of the upper parts is dark bluish-grey, Inclining to dull slate-black on the head, of which the central feathers along the crown form a gorgeous orange patch. It builds its nest on branches of trees; it is a rather bulky structure composed of twing and weel patch. It builds its nest on branches of trees; it is a rather bulky structure, composed of twigs and wool, or tow and cotton, and is very thick and snug. It scarcely deserves its ngly appellation, as it is only at those periods when its mate is attached to the nest by care for her little brood, that this fly-catcher is more fierce or tyrannical than any other. At such times, however, it cannot be denied that his conduct is rather outrageous. No matter the species of bird, no matter its size or strength, it is sufficient that it approaches any way near the tyrant's nest to excite his jealous rage, and out he sallies bent on instant satisfaction. It is said that engles and hawks may not with impunity approach this bird's nest, made sacred by his fledg-lings, and that, darting up into the air, it will launch down on to the back of its enemy, and there anchor in such a way as to make it a difficult matter to dislodge him. Only two small species of this tribe are found in this country. The European species are distinguished from any other by having much more slender bills, with shorter bristles at the gape.

Shorter bristles at the gape.

FLY, DEAGON. (See DIAGON-FLY.)

FLYING, fiving (Sax. fleegan, to fly), the power which many animals possess of raising themselves in the air, and in moving through it in various directions, supported by the atmosphere alone. (See Wing.)

FLYING, ARTIFICIAL, a species of propulsion through the air by means of mechanical or artificial contributes often attempted by men. The art of

contrivances, often attempted by man. The art of flying, if it can be called an art, has been often attempted: even amongst the ancients it was tried, and, we are informed, succeeded to some slight extent, Friar Bacon affirms, in his writings, that this art is not only possible, but he also informs us that he himself knew how to construct a machine in which a man, in a sitting position, might be able to transport himself through the sir like one of the feathered tribe. This through the air like one of the feathered tribe. This secret of Friar Eacon consisted of a very simple mechanical contrivance: it was a pair of globes made of hollow copper, exhausted of air, on which a chair could be supported, by which means a man could float in the atmosphere above the earth, and could buoy himself along. Another friar asserts the truth of this invention, or, at least, of one similar. Father Francisco Lana declares that a round vessel of plate-treas fourteen feet in diameter, weighing these cures. brass, fourteen feet in diameter, weighing three ounces per square foot, will only weigh 1,848 oz.; whereas a quantity of common air of the same bulk will weigh quantity of common air of the same bulk will weigh one of a membrae connecting its limbs with each 2,155? oz.; consequently, he deduces the fact that

## Flying Lemur

the globe will not only be sustained in the air, but that it will be capable of supporting a weight of 3733 oz.; and, also, that a globe of the same weight, but greater in capacity, would support a man. This, however, is a fallacy; for, from the fact of nature abhorring a vacuum, the globe would be crushed in by the superior force of the atmosphere. At many periods this subject has been taken up by philosophere, particularly in the reign of Charles II.; and it has been asserted that, at no distant period, by the march of improvement, flying in the air will be made as easy as walking on the earth. The truth of this assertion is, however, much earth. The truth of this assertion is, however, much to be questioned.

FLYING DEAGON. (See DRAGON.)

FLYING-PERGON. (See DRAGON.)

FLYING-FISH (Exocatus), a gen. of fishes that, on account of the extraordinary length and size of their pectoral fins, are enabled to spring from the water and support a kind of temporary flight through the sir. Their distinguishing features are—pectoral fins nearly equal to the body in length; head flattened above and on the sides; the lower part of the body furnished with a longitudinal series of carinated scales on each side; dorsal fin placed above the anal; eyes large; jaws furnished with small pointed teeth. Although some few naturalists have supposed that these fish possess the true power of flying, that is, by beating fish possess the true power of flying, that is, by beating the sir with their members, it is generally agreed that their large fins sustain them, parachute-wise, when they have leapt from the water. "I have never been able to see any percussion of the pectoral fins during flight, and the greatest length of time that I have seen this fish on the fin has been thirty seconds, by the watch; and the longest flight mentioned by Captain Hall is two hundred yards; but he thinks that subsequent obser-vation has extended the space. The most usual height of flight, as seen above the surface of the water, is from two to three feet; but I have known them come on board a ship at a height of fourteen feet; and they have been well ascertained to have come into the channels of a man-of-war, which is considered as high as twenty feet and upwards. But it must not be supposed they have the power of elevating themselves after leaving their native element; for, on watching them, I have often seen them fall much below the elevation at which they first rose from the water, but never in any one instance could I observe them rise from the height at which they at first sprang; for I regard the elevation they take to depend on the power of the first spring or leap they make on leaving their native element."—(Wanderings in New South Wales. Bennett.) Several instances are on record of the appearance of flying-fishes off the British coast, but the species is doubtful. It is probable that both the oceanic flying-fish (Exocatus volitans) and the Mediterranean flying-fish (Exocatus exilient) may have made their appearance in our seas. In the Gulf of Mexico are found some species with curious appendages or filaments attached to the lower

FLYING FOX (Pteropus rubricollis).—This animal belongs to the Bat tribe, of which it is the largest belongs to the Bat tribe, of which he has an employed species. It derives its common name of flying fox from a fancied resemblance of its head to that of a fox. It is found in the islands of the Eastern Archivalum where it occurs in great numbers. These pelago, where it occurs in great numbers. These animals are vegetarians in their diet, and commit great ravages in the gardens and plantations in the countries in which they abound. That they may occasionally live on animal food, is inferred from the fact that when in confinement, they have been known to devour the flesh of birds with great avidity. Like the rest of the bats, they are nocturnal in their habits, and, during the day, they remain suspended from the trunks of trees, usually affecting those of the fig genus for this clinging attitude, that any one not acquainted with the habita of the flying fox might readily mistake them for part of the tree itself, and only be undeceived when, dis-turbed by his presence, the seemingly long, pendent fruit suddenly assumed animal life and fluttered in masses round and round their roost.

FLYING LEMUR, or Colugo (Galeopitheess volums).

This is another curious species, which possesses the power of flying or lesping considerable distances, by

# Flying Squirrel

between the Quadrumqua and the Cheiroptera; to the latter, indeed, it has a great resemblance, insomuch as many naturalists of eminence have placed it in that order. It differs, however, from the bats in many respects, not the least important deviation of which is respects, not too least important deviation of which is the absence of opposable thumbs on all the feet, which are composed of five flagers united by a membrane. Notwithstanding this, it certainly hears, in its appear-ance and habits, a remarkable similarity to the flying for. In its diet, it is both carnivorous and frugivofox. In its diet, it is both earnivorous and frugivorous; feeding on birds and their eggs, insects, and fruits. It is found in the Indian Archipelago, living in the forests; seeking by night for its food, and remaining in a dormant state during the day, as already related of the flying fox. The natives occasionally eat this animal; but fastidious judges pronounce its flesh as being extremely nauseous.

FLYING SQUIREL.—By this name are known several species of aquirrels, the more important being the Tagram flying squirrel (Pteromys athmus), which is

Taguan flying squirrel (Pteromys alpinus), which is a native of India, where it is tolerably abundant. It has derived its name from the parachute-like appen-dage which it possesses. This consists of a broad fold of skin, stretching along each side of the animal, from the fore to the hind legs; and when it intends making a leap, it expands this curious membrane to the fullest extent, and is thereby enabled to jump a considerable distance, and is thereby endown to the head of distance, although always downwards, which, in fact, is all its so-called "flying" properties are capable of. It measures about three feet in length, of which it tail occupies more than half. Its general colour is chestaut, deepening into brown on the back and red on the sides; the abdomen, throat, and breast are covered with silvery greyish-white fur. The tail is greyishblack, becoming much darker towards its extremity. The assapan, or flying squirrel of America (Sciuropterus volucella) is another variety, agreeing with the above in its leading characteristics. There is also the polatouche of Siberia and the rusco of India.

FLY-WHEEL, in Mechan, a wheel with a heavy rim, placed on the shaft of any machinery put in motion by any irregular or intermitting force, for the purpose of rendering the motion equal and regular by means of its momentum. The rim of a fly-wheel, after a few revolutions, acquires a momentum sufficient to cause it to revolve with a velocity depending upon the resistance of the machinery. In all cases where a rotary motion is to be obtained from a reciprocating one by means of a crank, a fly-wheel is necessary to continue the motion at those two points of the revolution in which the crank lies in the direction in which the moving force acts. The momentum acquired by the fly-wheel urges the crank forward in the direction in which it was previously moving, and continues the rotation; thus making the motion equal and uniform.

FOCAL DISTANCE, fo-kell' (Lat. focus, a hearth), in Optics, the distance between the centre of a lens, or

concave mirror, and the point to which the refracted

or reflected rays converge. FOCUS, fo-kus' (Lat. focus, a hearth).—When light is reflected from regular curved concave surfaces to that all the rays converge to one point, that point is called the focus. The same term is applied to that point towards which rays of light converge after passing through a refracting medium, such as a lens. telescope, or other optical instrument, is said to be in focus when the arrangement of lenses is such that the object examined falls clearly and distinctly upon the retins of the observer. In the reflexion of heat, the point to which the rays converge is also called focus. In Geom. and comic sections, the term focus is applied to certain points in the parabola, ellipsis, and hyperbola, where the rays reflected from all these

curres converge and meet.

FODER, fod-der (Sax. fodder, or fother), in Agr., a serm used to express the food given to suimals; such

989

#### Folk-lore

these terms are rather arbitrary, and the one is frequently used for the other. (See Paysiology.)

Francoulum, fe-sik-sims (from Lat.famus), in Bot.,

the Fennel, a gen. of the nat. ord. Umbellifere, formerly placed under Anethum species, namely, F. vulgare, the common fennel, and F. dulce, the sweet fennel, are much used in this country as potherbs, and for garnishing dishes. The former dishes. The former grows wild on rocks and walls, particularly near the sea; the latter is frequently regarded as a cultivated variety of the same plant. F. capensis is a common esculent at the Cape of Good Hope. The term is derived from the Latin

PENNEL.

word for usury, because the seed yields, or is returned

with, great increase.

with, great increase.

Fog. (See Mist.)

Fog. (See Mist.)

Fog. Siewals, fog sig'-nüls (Dan. fog; Fr. signal, signal), are those used at sea in order to prevent colisions between vessels when any thick fog or mist is hanging over the water. They usually consist of blowing a horn, beating a drum, ringing bells, or firing off guns at stated intervals. The Admiralty has fixed rules for ships belonging to the navy to adhere to duving any fog, and certain known signals have been during any fog, and certain known signals have been devised in order to let the other vessels of a fleet know what tack an approaching vessel is on. At the present time, by reason of our extended commerce, the Channel and other maritime highways are much crowded, and it would be as well for the merchant service to lay down a plan of rules somewhat similar to those used by the Admiralty. As the generality of vessels in the present day are propelled by steam, it would not be add plan to use the steam-whistle, as is done on rail-ways; and different durstions of the whistle might express the different tacks on which a vessel might be. Ref. English Cyclopedia.

FOIL, foil (Fr. feuille, a leaf), a term applied to a thin sheet of metal placed beneath transparent jewels thin sheet of metal placed beneath transparent jewens to heighter their colour and improve their briliancy; also to those sheets of tin amalgam placed behind currors to make them reflect perfect images. They are made of tin, copper, and sivered copper, and are much used in imitations of precious stones. and are much used in imitations of precious stones. Coloured foils are made by coating the white with any varnish of the required tint. The sheet-lead which is used for the lining of tea-chests is a species of foil, and the Chinese purchase about 4,000 tons of lead annually from England for this purpose.

FOLL. (See FERGING.)

FOLLO, fo'-le-o (Ital., a leaf), as used in Book-keeping, denotes a page, or rather the two right and left-hand pages of an account-book, which are reckoned as one. In lat, it is used to denote the size of a volume of

one. In Lit., it is used to denote the size of a volume; thus a folio volume, or a book in folio, is one in which the sheet is only folded in two, each leaf making half a sheet.

FOLK-LORE, foke'-lore (Ang.-Sax.), is a word which has been recently applied, in the English language, to the ideas, prejudices, and superstitions—such as legends, and other similar stories—of the lower orders. The term is generally applied to all those customs and old habits generally handed down from father to son old habits generally handed down from nature to som old retired country villages and parishes; and the folk-lore of England, Scotland, Ireland, and Wales, would form sufficient matter to fill more than a volume. The fairy takes of the Irish, the "second sight" of the Scotch, the time-honoured old customs of the English, and the legends of the Weish, are so many instances of what is meant to be designated by "folk-lore." Old Restate and Christians correspondents may also be recorded. serm used to express the food given to suimals; such as the stems and leaves of plants; in fact, whatever is given as ordinary food is termed fodder, white corn, cats, beans, &c., are termed solid food. In some parts, hay and straw mingled together is peculiarly denominated fodder.

FGTUS, fe-lus (Lat., from feo, I bring forth), in Physiol., is applied to the child in the uterus from the fifth month of pregnancy to the time of birth. Previous to that time, it is commonly salight the embryo; but the weather are examples of folk-lore. In some parts

## Folkmote

of the country, if the salt at the dinner table is seen to be damp, people immediately assert that there is going to be rain; if the glow-worms are seen shining at night, "there will be wet ere morn;" if woodpeckers utter their harsh cry, "there will be a shower soon." With regard to gardening operations, there is an old rustic prophecy,

"When elm-leaves are as big as a shilling, Plant kidney-beans, if to plant 'em you're willing; When elm-leaves are as big as a penny, You must plant kidney-beans, if you mean to have any.

On New Year's day, old gossips relate, that if the first on New Years any, our goes person, you will have good luck for a twelvemouth; if a female, the reverse. In illustrating particular periods in history, folk-lore is sometimes a valuable adjunct.

FOLKMOTE, or FOLKGEMOTE, folk-mote (Sax., an assembly of the folk or people), in Anglo-Saxon times,

was applied to certain assemblies of the people; but respecting the exact nature of which, antiquarians are not agreed. According to some, it was a kind of annual parliament or convention, assembled on every May-day, for considering and ordering the matters of the realm. Others think that it was not essentially distinct from the shiremote, or common general meeting of a county; while some speak of it as an inferior ordinary court, held once a month, to settle minor disputes among the people. According to Kennet, it was a common council of all the inhabitants of a city, town, or borough, convened together in the motehail

FOLLICLE, fol'-le-kl (Lat. folliculus), in Bot., a superior one-celled, one- or many-seeded fruit, dehiscing by the ventral suture only; and consequently one-By the latter character it is known at once valved. from the legume, which opens by two sutures, and is two-valved; in other respects, the two fruits are alike. Examples occur in the columbine, larkspur, hellebore,

and aconite.

FOMENTATION, fo-men-tai'-shun (Lat. fomentatio, from force, I buthe), in Med., is the application of leat and moisture to a part, by means of flamed or other substance wrung out of hot water, in order to relieve pain or to stimulate the surface. Sometimes the water is medicated with various substances, and the water is medicated with various successionally other liquids, as oil or milk, are employed. Care should be taken to wring the cloths well, so as to prevent the fluid from running about the patient and rendering him uncomfortable. They should be and rendering him uncomfortable. They should be applied as warm as they can be borne, and renewed as soon as they begin to feel cold. To enable them to retain the heat still longer, they are often covered

externally with oiled silk.

FONT, font (Lat. fons, a fountain), a stone vessel in the form of a large bowl or basin, resting on a pedestal, and used for the reception of water required in the administration of the secrement of baptism. The pedestal is perforated to receive a pipe, by which the consecrated water may be carried off at the conclusion of the ceremony. The proper position for the fort is at the west mony. The proper position for the font is at the west end of the church, opposite the principal porch or entrance, which is to be found most frequently on the south side of the nave in parish churches, though in some instances it is situated on the north. Baptism was administered in the early churches in a part that was separated from the nave for that especial purpose by a purty-wall or screen, or in a building that was entirely distinct from the church itself. These were called buptisteries (see BATTISTERY), and contained a marble basin of great size in the centre, in which the candidate for baptism was subjected to total immersion. Subsequently, when this practice, which must have been attended with considerable danger in cold climates, attended with considerable danger in cold climates, particularly to infants, was abandoned for that of sprinkling those who were brought to be baptized with a few drops of water only, the font was introduced to take the place of the large laver of the baptistery, although it was still sufficiently large to admit of the total immersion of an infant, should this be desired by its parents. It was not then so necessary to have a distinct building in which thesefont might be placed, or its perents. It was not then so necessary to have a kinde of food, Potassium is found in various distinct building in which thegiont might be placed, or to have a portion of the church separated from the rest for its reception; and it was therefore put in the body food, but also from drinking-water, which usually food, but also from drinking-water, which usually

## Food and Drink

of the building, at the lower end of the nave. Examples occur, however, in some of our cathedrals and old churches, in which the font is placed in a baptistery divided from the body of the building; and in some of our modern ecclesiastical structures, it has been placed in an inclosure formed by low walls, or in a chamber especially designed and constructed for it in the basement of the belief that the constructed for it in the basement of the belief the constructed. ment of the belfry tower. The fonts that were placed in churches built in the Anglo-Saxon and Anglo-Norman atyles of architecture, were generally circular or square, supported on a short but massive pedestal, cylindrical in form. In some examples of square fonts, the lower corners of the block are cut away in such a manner that the faces of the sides assume the form of a semicircle. The bowl itself, and sometimes the stem, was often adorned with sculptured figures, acroll-work, or interlaced fret-work. The fonts of the three periods of English Gothio architecture are more frequently octagonal in form, and more richly carved with figures and emblems placed in sunken panels or niches, and the angles of the pedestal are adorned with buttresses. the angles of the pedestal are adorned with buttresses. They are also generally raised on a platform, formed of two or three steps. Those of the Perpendicular, or third Pointed style, were generally surmounted by a lofty octagonal canopy in the form of a spire, which was formed of wood, and magnificently carved and embellished with crockets at the angles, and a rich finial at the summit. This custom of covering fonts originated about 1250, in an order that was issued to the clerey to provide covers for these yeasels, which the clergy to provide covers for these vessels, which were to be kept locked. In a few of our churches the were to be kept locked. In a tew of our entrenes the fonts are made of lead, cast in a mould; many of these are covered with figures in bas-relief. They are supposed to have been executed by workmen of no ordinary skill, about the beginning of the 12th century.—Eef. Paley's Illustrations of Buptismal Fonts. FONTSWALET, font-te-vool, in Ecclesiastical History, was the name of a monkish order connected with the Repedictines, which areas in the 12th century.

the Benedictines, which arose in the 12th century, and was named after its first monastery. Its founder was Robert d'Arbrissel, and it comprised both monks and nuns; but had this peculiarity, that the latter had the pre-eminence, and the whole were subjected to an abbess, in imitation, as he said, of Christ's commenda-tion of the apostle John to the matronage of the Virgin. This order had several houses in England, and

Virgin. This order had several houses in Engianu, and at the time of the French revolution they had about fixty houses in France. FOOD AND DRINK, food (Sax. food, food), those solid and liquid substances which are used either for sustaining animal life or for the purpose of reproducing the ever-wasting tissues and fluids of animal bodies. Of the elementary bodies, only a small proportion enter into the constitution of animals; and the sub-stances included in this small proportion are the only ones required to be present in food and drink. Out of about sixty elements, only oxygen, hydrogen, nitrogen, carbon, sulphur, phosphorus, chlorine, sodium, potassium, calcium, magnesium, iron, and fluorine, are absolutely necessary. Albumen, fibrine, and caseine, which occur both in animals and vegetables, caseine, which occur both in animals and vegetaries, together with vegetable gluten, furnish oxygen, hydrogen, mitrogen, and carbon. Animal flesh, eggs, milk, corn, and various other vegetable productions, contain one or more of these principles. Food concontain one or more of these properties extended as large proportion either of sugar, starch, or organic acids, introduces carbon, hydrogen, and oxygen largely into the system. Oleaginous alimentary substances contain carbon with a little oxygen and substances contain carron with a first dayger and hydrogen; this class of substances includes iat, suct, butter, oily seeds, such as nuts, and fatty foods, such as liver, &c. Flesh, blood, and bones, used as food, supply phosphorus to the system; the flesh of fishes is particularly rich in phosphorus; and in the shape is particularly rich in phosphorus; and in the shape is particularly rich in phosphorus; and in the shape of phosphates, it exists in the juices of many edible vegetables. Sulphur is introduced into the system from the fibrine of flesh, from albumen, from the caseine of milk, gluten, &c. Chlorine and sodium exist in nearly every variety of animal food, and, in the shape of common salt, are taken separately with nearly all kinds of food. Potassium is found in various kinds of food both animal and vecetable: in milk: in

# Food and Drink contains sulphate and carbonate of lime in solution

Magnesium is generally found along with calcium, and traces of fluorine have been observed in milk, blood, &c. These simple bodies are, however, not capable of being directly assimilated and converted into tissue; they must be previously in combination; and their assimilation depends upon certain chemical decompositions and physiological processes. The number of elementary substances in combination differs : thus, water contains two elements,—oxygen and hydrogen; sugar, starch, fat, &c., contain three; caseine of milk contains five; and albumen and fibrine contain six. Baron Liebig, who has given much attention to this subject, has divided all kinds of food into two classes, those substances which do contain nitrogen and those which do not. The first class, which is sometimes called nitrogenous or albuminous, is useful in forming blood, flesh, &c.; it is, in fact, nutritious food. The second, or non-nitrogenous class, assists the respiratory organs. Thus, in very cold climates, where more exercise is required in order to sustain the vital heat, more oxygen is consumed, and consequently more carbon is required in the food. Hence, it will be observed, that in such countries as Siberia, Lapland, &c., large quantities of non-nitrogenous substances, such as fat, oil, &c., are used by the inhabitants as food. In the temperate zone a moderate mixture of nitrogenous and non-nitrogenous food is used; while, nitrogenous and non-nitrogenous food is used; while, in the tropics, where the system requires oxygen in particular, fruits and regetables form the principal food. Aithough the theories of Liebig have not remained undisputed, his works on the subject are considered of very high value. (See Liebig's Researches on the Chemistry of Food.) In the preparation of food for eating, much depends upon the way in which it is cooked. As all the nutritious juices of meat are soluble in cold water, it is necessary, when preparing boiled food, to piace the meat in boiling water in the first place. This coagulates the albumen on the surface: thus forming a crust or shell, which prevents first place. This coagulates the albumen on the surface; thus forming a crust or shell, which prevents the secape of the nutritious juices. If, however, the object is to make soup, the meat should be put into cold water, and gradually raised to the boiling-point, In roasting and broiling meat, the first application of heat should be vigorous and rapid, in order to coagulate the albumen and form a crust, and so retain the miner are in boiling. In the research of versions the juices, as in boiling. In the process of roasting, the cellular tissue is converted into soluble gelatine, and the fat is melted out of its component cells. Baked meat is less digestible than either roast or boiled, as it contains more empyreumatic oil. Frying is the most unwholesome form of cooking, as it is mostly performed with the assistance of heated oil or fat, which is decomposed during the operation. Smoking, pickling, and salting meat, not only harden the animal textures, but, in the case of salting, the food is rendered less nutritions, as a large quantity of albumen, soluble phosphates, lactic scid, potash, creatine, and creatinine, are abstracted in the brine. Very few togetables are roasted; they are, as a general rule, boiled. Those which contain saccharine matter, such as carrots, beetroot, parsnips, &c., are best cooked by steam, as boiling water dissolves out a large quantity of their nutritions ingredients. Vegetables, however, which contain much starch, as potstoses, should be boiled. By boiling, the granules of the starch are ruptured and partially dissolved, and any volatile oils which may be present are expelled. All kinds of flesh are not equal with regard to their nutritive value. Veal, for instance, is totally different from beef. It contains a smaller quantity of the alkalies, and there is 15 per cent. more phosphoric acid than is necessary for the formation of salts; it contains, also, little of the fibrine of flesh, and proportionately more of the fibrine of blood, which is less digestible than the former. Veal is rich in gelatine, which is not nutritious, and seldom contains any quantity of fat: it also tity of their nutritions ingredients. Vegetables, how former. Veal is rich in gelatine, which is not nutritions, and seldom contains any quantity of fat: it also contains very little iron. In all these points it is also reverse of beef. Hard-boiled eggs have little or no nutritive power, and the same may be said of boiled fish, the soup of which is generally thrown away. In order to make up the necessary deficiency of nutritive matter in veal, eggs, and fish, vegetables should be taken with them. Celery contains 18 per cent., soft the intervent of cold; but this mode of preserva
864

## Food, Preservation of

dry weight of salts, alkalies, and alkaline earths. Vegetable food in general contains a large proportion of iron. In the human body, iron is present in the blood, the bile, and other places. The presence of iron determines the colour of the hair, and persons of a sanguine temperament have more iron in their bodies than those of a lymphatic nature. When the blood is deficient in iron, the physician prescribes either iron, steel, or chalybeate waters. The presence of this metal is therefore necessary in food: Prolonged absence from fruits and aucoulent vegetables brings on scurry. The absence of the acids which they contain produces this effect; thus the actor which they contain produces this circle; thus lime-juice is used by sailors with good effect on long journeys. Amongst the condiments used for flavouring food, are mustard, cay sone pepper, black pepper, and various spices. They owe their action to the presence of a volatile oil. The volatile oils of fennel, thyme, or a volatile oil. The volatile oils of tennes, trying-parsicy, anise, caraway, horseradish, mustard, and water-cress, stimulate the system, but do not incorpo-rate themselves. Condiments and sauces (which are usually fluid mixtures of condiments), in time, generally weaken the organs, which they at first stimulate. The only exceptions are salt and vinegar. Dr. Beaumont, a surgeon in the United States army, about forty years ago, made some interesting experiments upon a Canadian who had been shot in the left side. In the process of healing, an aperture was left, by means of of healing, an aperture was left, by means of which Dr. Beaumont was able to observe everything that took place in the atomach. According to his observations, vinegar and mustard, when used together, bear some analogy to the gastric juice. (See "Experiments and Observations on the Gastric Juice, and the Physiology of Digestion," by Dr. Beaumont.) Drinks for the most part are simply liquid food. They may be divided into the following classes:—1. Mucilsginous, farinaeous, or saccharine drinks; such as barley-water, and sucré, &c. They are a little more nutritive than drinking-water.—2. Aromatic or stringent drinks; such as tea, coffee, chocolate, cocos, &c. They all contain principles which act with a slightly exhibitating action upon the nerrous system: chocolate and coeoa contain oil and starch.—3. Acidulous drinks; such as lemonade, ginger beer, raspberry vinegar, &c. They allay thirst, and form cooling antiscorbutic drinks.—4. Drinks containing calculus. and form cooling antiscoroute drinks.—a. Drinks constaining gelatine and ozmazome, including broths and soups. These, when properly made, ought to contain all the soluble constituents of the substance from which they are prepared.—5. Emulsive or milky drinks; such as animal milk, cocos-nut milk, almond milk, &c. Animal milk contains all the essential ingredients of Aumai mis Courses at the cessessa ingresses food; the others are slightly nutritive.—B. Alcoholic and other intericating drinks, including malt liquor or beer, wines and spirits. (See article on Deinks.)—Ref. Percira's Treatise on Food and Diet.

FOOD, ADULTERATION OF, the act of corrupting food by a foreign mixture, or of endeavouring to make inferior qualities of food pass for more than their intrinsic value, by their resemblance to something better. The adulterations practised differ in king as well as degree. One form of adulteration consists in the addition of substances usually of a greatly inferior value, for the sake of bulk and weight. In this case, the choice of the adulterating substance depends upon its chespness and fitness for the particular adulteration required. This description of adulteration is the one most frequently practised. A second form of adultera-tion consists in the addition of colouring matters, with a view to heighten the colour and improve the appearance of the article, as well as to conceal other forms of adulteration. This form of adulteration is the most objectionable of all, as several substances are employed for giving colour, which are not only nurtful, but in some cases poisonous. Various preparations of lead, copper, mercury, and arsenic, are used for this pur-pose. Another kind of adulteration consists in the mixture of substances, for the purpose of imparting

## Fool, Court

#### **Foraminifera**

tion is necessarily very limited in practice. The second method is by keeping the food in air-tight vessels. This plan, although expensive, is the most efficacious, and the one most generally adopted: several great improvements have been made upon it in late years. The usual method of keeping meat for any length of time is by salting it; but, as has been pointed out in the article upon Food and Drink, the operation of salting deteriorates the nutritious power of the food. (See ANTISEPTICS.)

FOOD, COURT. (See COURT FOOL.)
FOOLS, PRAFT OF, fools (Fr. fol, fou), was the name of a festival regularly celebrated, with the most absurd of a results regularly cerebrated, with the most gostra ceremonies, both by clergy and laity, in several countries of Europe, from the 5th down to the 16th century, It is said to have been introduced in imitation of the Roman Saturnalia, and its celebration took place about the same time, the great day being New Year's day; but the eeremonies were often continued from Christ-mas to the last Sunday of Epiphany. At first only the boys of the choir and young sacristans played the principal part in them; but afterwards all the inferior servants of the church, and even laymen, engaged in them; while the bishop and other clergy formed part of the audience, A Bishop of Unreason was appointed, the forms and coremonies of the Church were travesticd, indecent songs were sung, dancing was carried on, and all manner of fooleries enacted. The ass often played an important part in the profeedings, being sometimes led towards the altar and having hymns sung in its honour. The feast of fools was condemned by several popes and bishops in the 16th century, and the council of Basle, in 1435, expressed its detestation of this and account of the features, but it continued to be observed. several other festivals; but it continued to be observed

in many places down to the time of the Reformation.

FOOLS' PARSLEY. (See ÆTHUSA.)

FOOT, foot (Ger. fues, Lat. pes), in Anat., is that part of the lower extremity below the leg with which we stand and walk. It is composed of three series or groups of bones,—the tarsal, or bindermost; the metatarsal, which occupy the middle portion; and the phalanges, which go to form the toes. The tarsal bones are seven in number. Above, they are connected with the tibia and fibula bones of the leg, and below form the heel and the hinder part of the instep. They are the astragalus, which articulates with the tibia and tibula; the os calcis, or bone of the heel; the os naviculars, or scaphoid bone, on the inner side of the foot, articulating with the astragalus; the os cuboides, on the outer side of the foot, articulating with the os calcis; the three ounciform or wedge-shaped bones (the internal, middle, and external) in front of the scaphoid bone, near the middle of the foot. The metatareal bones are five in number, and belong to the class of long bones. They are connected posteriorly with the tarsal, and anteriorly with the philangeal bones. One is attached anteriorly with the phalangeal bones. One is attaced to each of the coneiform bones, and two to the os cuboides; and they diverge slightly outwards as they proceed forward. Their auterior ends form the bulls of the toes. The first metatarsal bone is the shortest and strongest, while the second is the longest,—the others all decreasing in length according to their distance from it. These bones form the anterior portion of the instep. The phalanges, or bones of the toes, are or one instep. The phalanges, or bones of the foes, are fourteen in number, three to each toe, except the great one, which has only two. The upper ones, which are the longest and largest, are named the metatarsal, the next the middle, and the most anterior the ungual phalanges. The bones of the foot, more particularly those that compose the tarsus and metatarsus, are those that compose the tarsus and metatarus, are firmly connected tegether, so that they are not liable to be displaced; and those parts where they articulate with one another being covered with a tolerably thick layer of highly elastic cartilage, they possess a consi-derable degree of elasticity. They are bound together

885

calcis, by which the foot is rolled mwards and outwards; (3) between the first and second range of tarsal bone admitting of a very slight motion, by which the arch of the foot may be somewhat increased or diminished. Besides these there are the less-complicated movements of the metatarsal and phalangeal bones. The foot, natuof the metatarsal and phalangeal bones. The foot, naturally a beautiful structure, is usually so much interfered with in civilized life, as to be deprived of much of its beauty, and even of its utility. Its movements are impeded by its being confined in tight-fitting boots; while, in place of the boots being conformed to the shape of the feet, the feet are made to conform to the shape of the boots. The consequence of which are corns, bunions, cold feet, and a number of other evils, from which so many suffer in the present day. Attenton has lately here called to this subject by Professor trom which so many suffer in the present day. Attention has lately been called to this subject by Professor Meyer, of Zurich, who has published a pamphlet, entitled "Why the Shoe pinches; a contribution to applied Anatomy," which has been translated into English, and is well worth a perusal.

Foot, in Greek and Latin poetry, is a metre, or measure, composed of a certain number of long and short syllables. Some are dissyllabic. consisting of

measure, composed of a certain number of long and short syllables. Some are dissyllabic, consisting of two feet, us the spondee, iambus, trochee; and some trisyllabic, as the dactyl, anapest, tribrach. These are what are called simple feet. There are others, consisting of four, five, or six syllables, which are reckoned double or compound feet, but which are commonly resolved into single feet. A verse is frequently named from the number of feet which it quently named from the number of feet which it contains, or from the foot which prevails in it; as, heramater, containing six feet; pentameter, containing five; dactyllic, from the dactyl being the prevailing foot; ismbic, the ismbus.

FOOT-BALL, an old English out-of-door exercise or game, which used at one time to be a national pasgame, which used at one time to be a national pas-time; now, however, it has nearly fallen into disuse, except in some parts of the country. It is played with a distended ox-bladder, lightly covered with dressed leather, and so sewn up as to retain its elasticity. Two different sets or sides of players are chosen, and there is a goal marked out on the extremity of the space allotted to each side. When all is ready, "play" is called, and the ball thrown up between the two sides. The object then of each is to endeavour to send this ball through the boundary or goal of their adversaries' ground, by means of vigorous kicks. The ball can never be sent forward fairly unless kicked, and this is one of the most stringent rules of the game. On the Scotch border it is still played annually by the men of Scotch forder it is still played annually by the men of different clans; and it is one of the most interesting of sights to see the two parties engaged in that amicable contest. From the fact of kicking being one of its strongest characteristics, this game is generally productive of broken shins and other contusions. It is still a favourite pastime in the large public schools of England.

FORGE, for of (Fr. fourrage), a military term applied to hay, oats, corn, barley, grass, clover, and other means of sustenance for horses brought into

camp by troops with that object.

FORAMEN, for d-men (Lat., a hole), in Anat., is a term applied to certain holes or openings of the human body, more particularly of the skeleton; as the various foramina of the skull. The foramen ocale is a passage or communication between the two auricles of the

heart in the fœtus.

heart in the fætus.

FORMINITERA, fo-rå-me-nif'-e-rå (Lat. foramen, an oriflee; fero, I bear), the name given by d'Orsigny to a group of minute organisms having calcareous shells, which are pierced with numerous holes or foramina. Until recently, the Foraminifera were regarded as microscopic cephalopods, but they are now looked upon as protozos. The pores are for the protrusion of delicate filaments, by the aid of which locomotion and perhaps nutrition are performed. Hecent Foraminifera are beautiful microscopic objects; they are procured by dredging, or sometimes from the sand of the sea-shore. In the fossil state these tiny shells occur in rocks of all derable degree of elasticity. They are bound together in various directions, by a number of ligaments, one of the principal of which is the plantar ligaments, one of great strength, and passes from the under surface of the heel-bone, near its extremity, forward to the lends of the metatarsal bones. The movements of the foot, which are permitted by the connecting ligaments, are effected by a variety of muscles. The principal movements are, (1) that at the arble, formed by the tibia and fibula with the astragalus, by which the foot is bent and straightened; (2) between the astragalus and os

## Forbes Mackenzie Act

ranean regions, and of which the pyramids of Egypt are principally composed, agree in essential struct with those of the Foraminifera.

FORESS MACKETZIE ACT is the name popularly given to act 18 & 17 Vict. c. 67, entitled, "An act for the better regulation of public-houses in Scotland," and which is so called from the late Mr. Forbes Macketzie, M.P., the member by whom the bill was introduced. Some of the enactments of this statute are very stringent; but there can be little doubt that, as a whole, it has been attended with beneficial results. No excisable liquors are sliowed to be sold on Sunday, or after eleven o'clock at night on any other day, except in the case of inn and hotel keepers, to bond fide travellers or persons lodging in their house. Grocers and provisiondealers, who may be licensed to sell excisable liquors, are prohibited from allowing it to be drunk upon the premises; and in the same way all public-house keepers who sell liquors to be consumed on the premises are who sell future to be consumed on the premises are not allowed to sell groceries or other provisions to be consumed elsewhere. In and hotel keepers, and keepers of public-houses, are prohibited from selling or giving out any liquor before eight o'clock in the morning; but grocers and provision-dealers, having a spirit license, are allowed to sell spirits after six o'clock. 1859, a royal commission was appointed to inquire into the working of this act, and after collecting a great amount of evidence, they expressed themselves generally in favour of the act, as having been productive of beneficial results, but suggested a number of alterations, partly with a view to enabling the police to carry out its provisions with greater efficiency, and partly to lighten some of its more stringent enactments.

Ighten some of its more stringent enactments.

FOREIDEN FRUIT. (See CIRUS.)

FORCE, FORCES, fors (Fr.).—In Mech., force is a term applied to any cause which is capable of producing motion in matter, or of stopping or altering its direction when produced. Every visible particle of matter is under the influence of several forces, exerted upon it both by distant and by seincent particles, and upon which it acts in return; for the action of one body on another is always accompanied by a re-action of the latter upon the former, of the same intensity, in an opposite direction. The motions observed in some bodies are owing to these forces, and upon their balance the apparent state of rest in others is de-pendent, According to Sir John Herschel, the origin of the idea of force must be referred to the conpendent. According to Sir John Herschel, the origin of the idea of force must be referred to the consciousness of each individual. He says: "We are conscious of a power to move our own limbs, and by their intervention, other bodies; and this effect is the result of a certain inexplicable process, which we are aware of, by which we exert force; and even when such exertion produces no visible effect (as when we press our two hands violently together, so as just to oppose each other's effort), we still perceive, by the fatigue and exhaustion, and by the impossibility of maintaining the effort lone, that something is going on within us, of effort long, that something is going on within us, of which the mind is the agent, and the will the determining cause." In the case of force exerted by the right ing cause." In the case of force exerted by the right hand, and met by an equal force from the left, the two, acting in opposite directions, exactly neutralize each other, and may be said to be in equilibrio. and the effect is called pressure. As this force is found to have its proximate seat in the muscles of man and other animals, it is called muscular or animal force. This force can be communicated to inanimate matter, as when a stone is projected from the hand. Muscular force may also be concentrated in the same mass by continued action. per concentrated in the same mass by continued action, as when a stone, by means of a sling, is continuously acted upon by the same arm, it will at length be projected with an intensity of action capable of producing very violent effects. Force transferred to moving masses of matter is called mechanical force, and by multiplying the quantity of matter in a body by its by multiplying the quantity of matter in a body by its velocity, we arrive at its momentum, or the quantity of force which it is capable of exerting upon other bodies opposed to it. The investigation of the laws of, motion constitutes the province of Dynamics. In mechanics, the term decomposition of forces significantly and the control of the contro in mechanics, take term decomposition of forces. Any force may be decomposed or resolved into a number of forces, and the original force will be equal to the resultant of those forces. Thus, if the given force be represented by the diagonal of a parallelogram, it can

## Forceps.

be resolved or decomposed into two forces of like intensity and direction, represented by the two sides of the parallelogram. Any one exerting muscular or animal force is soon made conscious that it may be opposed by other forces appertaining to inanimate matter. In lifting a lump of metal, stone, or other heavy substance from the ground, an opposing force is experienced, which is called weight or gravity. On pressing with the arm on a strong spring, another op-posing force is observed, called *elasticity*. Some forces possing force is observed, called tracticly. Some forces cause masses of matter to approach and others to recede from each other, retaining them in their second position against an opposing force: the former are called forces of attraction, and the latter of repulsion; thus, gravity is a force of attraction, and elasticity as force of repulsion. In electricity and magnetism the forces of attraction and repulsion are also shown. Polar forces of attraction and repulsion are also shown. Polar forces are those which are conceived to act in opposite directions at the extremities of the axes of molecules or of masses of matter. The forces mentioned above are usually termed external forces, for they act upon matter at sensible distances; but there are others which act only upon its constituent molecules at insensible distances: these are frequently called internal or molecular forces; they include homogeneous attraction or cohesion, the universal antagonist of which is the repulsive force of heat (which see). Another attrac-tive force is that of heterogeneous affinity, by which a piece of metal or glass is wetted when dipped into water. Heterogeneous attraction is seen in its highest degree in chemical affinity, an inquiry into the laws of which force constitutes the chemist's peculiar province. (See ioree constitutes the chemist's peculiar province. (See AFFINITY.) The correlation of the physical forces is a very important principle in natural philosophy, which has of late years been particularly enunciated by Mr. W. R. Grove, the inventor of the voltaic battery which goes by his name. Many philosophera had previously asserted that all the forces of nature were intimately connected, and dependent upon one common principle; but the correlation, or necessary mutual dependence and commutability of each of the physical forces upon and into any other, or into all, and of all, reciprocally into each other, was, at its original enunciation, the particular theory of Mr. Grove. His doctrine is, "that the various affections of matter which constitute the main objects of experimental physics,—namely, heat, light, electricity, magnetism, chemical affinity, and motion, are all correlative, or have a reciprocal dependence; that neither, taken abstractedly, can be said to be the essential cause of the others, but that either may produce or be convertible into a ible into any of the others: thus, heat may, mediately or immediately, produce electricity; electricity may produce heat; and so of the rest, each merging itself, as the force it produces becomes developed; and that the same must hold good of other forces, it being an irresistible inference from observed phenomena, that a force cannot originate otherwise than by devolution from some pre-existing force or forces."-Ref. Correlation of Physical Forces, by W. R. Grove.

FORCE AND FEAR, in Law, is a term applied to such restraint or interference with the freedom of action of an individual as will render an act performed by him, when in that condition, null and void. It is, therefore, not every kind of restraint that will have this effect in law. In fact, it must be of such a kind as may reasonably be supposed to have influenced his conduct; and hence, in questions of this kind, the age, sex, and other circumstances of the party, have to be taken into account. A contract entered into through force and fear is invalid. "Ff aman," says Blackstone, "through fear of death or mayhem, is prevailed upon to execute a deed, or do maynem, is prevailed upon to execute a deed, or do any other legal act; these, though accompanied with all other the requisite solemnities, may be atterwards avoided." But "a fear of battery, or being heaten, though never so well grounded, is no duress; neither is the fear of having one's house burned, or one's goods taken away and destroyed; because, in these cases, should the threat be performed, a man may have satis-

faction by recovering equivalent damages."

Forcurs, for eps (Lat.), in Surg., is the name given to certain instruments of various shapes, according to the purposes they are intended to serve; but the principle of all is that of a pair of pincers with

#### Forcible Entry

two blades, either with or without handles. They are much used in surgery, especially for taking hold of substances that cannot be conveniently laid hold of with the fingers. Certain kinds are used for tooth-drawing; others for securing the mouths of arteries, in order to their being tied; others are used in dissecting; others in lithotomy; and others in midwifery, for aid-ing delivery in difficult cases.

FORCIBLE ENTRY, or DETAINER, in Law, is an offence against the public peace, which is committed by violently taking or keeping possession of lands and by volefitly taking or keeping possession of lands and tenements with menaces, force, and arms, without the authority of law. This was formerly allowable in certain cases; but being proved very prejudicial to the public peace, it was found necessary, by several statutes, to restrain all persons from the use of such violence methods, even in doing themselves justice, much less if they had no justice in their claim; so that, now the only entry allowed by law is a peaceable one. now, the only entry allowed by law is a peaceable one.

FORCING, for sing (Fr. forcer, to force), a term applied to the system by which the growth and maturity of fruits, vegetables, and flowers are hastened by artificial The processes of forcing chiefly affect the admission of air, and the proper supplies of heat, light, and water. The grand effect is produced by heat; and the great art to be borne in mind is to supply only just so much of this as will harmonize with the light afforded by the sun, and the quantity of moisture which the nature of the plant under consideration requires. All the operations of nature being gradual, it will never do to accelerate the growth of plants to any very great extent, or in a hurry. The processes of forcing must, therefore, be conducted on a graduated scale; and the heat, light, and moisture must be increased by degrees, as the plant is approaching its maturity. It must be likewise considered that excites require a far higher temperature for forcing purposes than plants grown in a more moderate clime; and that, therefore, the latter must not be subjected to as great heat as the former. Forcing is generally carried on in what are termed hothouses, which are heated by stoves and built of glass, with paved floors, in order to allow the heat and light afforded by the sun to enter. The Dutch, who are particularly celebrated for this horti-Dutch, who are particularly celebrated for this horti-cultural art, however, carry on their forcing in pits heated by the fermentation of manure. Some of the best examples of forcing, as carried on in hothouses and other similar contrivances, can be seen at the Royal Horticultural Gardens, and at the gardens attached to the palace at Kew. For further informa-tion on the subject, the reader is referred to Loudon's "Encyclopedia of Gardening," which dilates at large moneths act of forcing. upon the art of forcing.

FORCING-PUMP. (See PUMP.)
FORD, ford (Sax. ford or fyrd), a name applied to that part of a river where the water is sufficiently shallow to admit of any person or persons crossing by means of wading, without having recourse to a bridge, ferry, or any other means of transportation. In military operations, fords are of the greatest service to an army. They are generally found, either in the widest part of a river, where the current is not so strong, or in a diagonal line with the salient angles of any bend of in a diagonal line with the sament angles of any owner of the stream. Fords for infantry, to be really useful, should not be more than three feet in depth, and those for cavalry should not exceed four feet. From the rapidity of some currents, fords of greater depth are generally

Fore, fore (Sax. fore, advanced), a nautical term, which includes all the distinguishing characteristics of that part of a ship's frame and belongings lying near

the stem; as fore-mast, fore-sheet, &c. &c.
FORECASTLE, fore-küs-tl, a short deck placed in front

of a ship above the upper deck. It is generally terminated at each end, in ships of war, by a breastwork, nated at each end, in sulps of war, by a breastwork, the foremost part reaching the beak-head, and the after portion reaching to the fore-chains. This part of a ship used to be very much elevated, in former times, for the accommodation of archers and cross-bowmen:

#### Fore-shortening

time, to call on a mortgagee who has possession of his estate, to deliver it back, and account for the rents and profits received, on payment of his whole debt and interest. But, on the other hand, the mortgagee may, where there is a power of sale in the deed, which is usual, either compel the sale of the estate, or call upon the mortgage to redeem it presently, or, in default thereof, to be for ever foreclosed from redeeming the same. For this purpose, the mortgagee files a bill of foreclosure; and if, on the day fixed for payment, the money be not forthcoming, the equity of redemption is declared to be forfeited, and the mortgagee obtains absolute possession of the estate.

gages obtains absolute possession of the estate.

CHANGE. )

FOREIGN ENLISTMENT ACTS .- By 3 Jac. I. c. 4, it was made felony for any person whatever to go out of the realm to serve any foreign prince, without having first taken the oath of allegiance before his departure; and by 29 Geo. II. c. 17, it was declared, that if any subject of Great Britain enlist himself, or if any person procure him to be enlisted in any foreign service, or detained or embarked him for that purpose, without license under the kings sign-manual, shall be guilty of felony, without benefit of the clergy. But these statutes were repealed by 59 Geo. III. c. 69, which enacts that any British subject thay be punished by fine and imprisonment, who shall enlist in any foreign service, or fit out vessels to be employed in the service of any foreign power, except by heense of the grown. the realm to serve any foreign prince, without having any foreign power, except by license of the crown.

FOREIGNER. (See ALIEN.) FORELAND, fore'-länd (Dan. land), a term which is nearly synonymous with promontory, cape, or head-land, applied to any projecting point of land running into the sea,—as the North and South Foreland at the nouth of the Thames. In Fort., the term is applied to the ground lying between the defences of any place or

fortress and the moat.

FORMOOK, forci-lok (Ang. sax.), the hair that grows from the fore part of the head. In nautical language, it is applied to a small flat-pointed wedge of iron, used at the end of a belt, to retain it in its place. The expression, to take time by the forelock, means to be early or first in setting about any undertaking.

FORE-SHORTERING, fore-short'-en-ing (Ang.-Sax.), an expression in Paint, and Persp. intended to convey the method of drawing, in strict accordance with the rules of perspective, the limbs or body of a human being, or the body of an animal, when we are looking directly against either of them, in a position which shows their breadth while it conceals their length, either entirely or par-tially. Or, in other words, fore-shortening occurs when the latter is either approaching or receding from us, and when the former is extended, either towards us or from us, in a direction varying from a line which is at right angles to the surface of the eye to another that is parallel with it; under the former of which conditions it would be seen fore-shortened to the greatest possible degree, while, under the latter, it would be viewed in its entire length. Great attention must be paid to the treatment of light and shadow in fore-shortening the arm, leg, or body of a human being, or the carcass and legs of an animal, that the effect or the carcass and legs of an animal, that the effect produced may convey a correct idea of the intention of the draughtaman, and that, although the object is shortened in drawing, so that the front or fore-part only is presented to the view of the spectator, it may be clearly seen that it possesses length, and, as in the case of an extended arm, that it is projecting from the trunk to an extent compatible with the position in which it is placed. Practice in fore-shortening may be best obtained by making drawings from plaster-casts heat obtained by making drawings from plaster-casts best obtained by maning drawings from plaster-custs of figures and animals placed in different positions; but the principle may be readily seen by placing a wooden cylinder on a vertical bar and turning it round, first in the norizontal plane passing through the eye of the observer, and then above and below that plane, while its outline assumes all forms between that of a while its outline assumes all forms between that of a summer or the control of th whence the term forecastle.

Whence the term forecastle.

Law, is the process by which a nortgagor is deprived, or foreclosed, of his right of redeeming the extreme, the cylinder will present examples of foremortgaged estate. By what is called the equity of shortening, although the term is more strictly confined to the view an object presents when its length is in a Sid 2 F 2

line perpendicular to the surface of the eye of the observer, or varying but little from it.

FOREST, for set, a large expanse of ground covered with trees. The word is derived from the low Lat. foresta, which is itself originated by the Ger. forst, forests, which is itself originated by the cor. fore, againfying the same thing. Forests are interesting in many ways, as they may be said to mark the track of civilization, besides being of the utmost utility to man, both from local as well as atmospherical influences. The Caledonian and Heroynian forests are the first we The Caledonian and Heroynian forests are the first we read of as celebrated in history; the former being the retreat of the Picts and Scots in North Britain, the latter extending from Switzerland to Transylvania. In the time of Cæsar, a journey through this forest was computed to last over sixty days, or more. Forests were greatly venerated by the Romans and other ancient peoples, temples being often erected and sacrifices ordained in their honour. This may be considered one of the greatest reasons for the Druids living in them, as it was thought much more sacred to dwell under trees than en plein champ—in the open field. Forests supply man with many necessaries. Timber Forests supply man with many necessaries. Timber and fuel, medicinal and nourishing plants, all trace their source to the luxuriant forest, which, moreover, affords shelter to the houseless and a field of occupation to the hunter. (For an account of the forests of England, see FOREST LAWS.) Forests abroad are mostly composed of (in Europe) calt, elm, beech, poplar, ash, alder, plane, willow, lime, and birch; not to speak of the numbers of wild apple, pear, and other furti-traces; besides pine, fir, and cypress in profusion. fruit-trees; besides pine, fir, and cypress in profusion, with all species of bushwood and vines. In Norway, the forest-land extends up to Drontheim, which is in latitude 63° north. Switzerland is well wooded, and oaks and firs are found at a level over 4,000 feet above the sea. France has some fine examples, her variety of climate being favourable to the growth of all species of trees, some of which, indeed, belong to a much warmer climate: the forest of Ardennes and the Bois de Boulogue may be mentioned as instances of the expanses she has covered with trees. In Italy, the plains of Ravenna afford a wide scope for the luxuriance of forest life, and the pine grows there very extensively; most of the oak, too, used in our navy for shipbuilding purposes, comes from Italy. Russia, however, bears away the palm for her abundance of forests, and some of the finest timber in the world comes from her ports of the finest timber in the world comes from her ports in the Baltic. The districts of Twer and Novgorod are regularly covered with wood, and the forest of Volkonsky is thought the largest in Europe. Poland, too, resembles Russia in this matter, and she may be considered the second well-wooded country. For the king of forests, the reader must look to the New World, where, in both the north and south of America, the vegetation appears to possess no limits. In North where, in both the north and south of America, the vegetation appears to possess no limits. In North America, the forests are gradually disappearing, through the immigration into the country and the diffusion of settlers; but in South America, the whole of the valley of the Amazon, which embraces one-third of the entire area of that country, is one vast forest. It would be impossible to give an account of the various descriptions of trees which are to be found there; for they are apparently without limit, and the size, of the individual trees is generally stucendous. It is there; for they are apparently without limit, and the size of the individual trees is generally stupendeus. It is recorded that a church at Chili, although it was sixty feet long, was built of one single tree. According to Humboldt, the direct influence of forests on climate is a diminution of temperature, which is effected either by screening the soil from the heat of the sun's rays; by the evaporation of moisture from the leaves; or, thirdly, by the uneven surface which the leaves offer to the cooling process of radiation. The indirect influence of forests is the due preservation of moisture in the different countries, in the supply of rivers, and in other ways.

FOREST LAWS (Ger. forst), in England, are laws for the regulation of the royal forests. A forest is, for the regulation of the royal forests. A forest is, properly, an extensive surface of country naturally covered with trees and undergrowth, as distinguished from a plantation which has been made by art. In justices in eyre, wardens, verderers, regarders, forescurity times a great part of England, as of most other countries of Europe, was covered with forests, which subsequently, as being waste lands, came to be resubsequently, as being waste lands, came to be regarded as the property of the crown, and, as abounding with game of various kinds, were carefully pro-

#### Forest Laws

tected, all persons being prohibited from hunting in them but the king, or persons authorized by him. After the time of the Conquest, the forests came to be guarded with greater strictness, their number was increased, and their bounds enlarged, and trespassers were punished with greater severity. Finally, a sys-tem of laws and courts for their administration was tem of laws and courts for their administration was established, by which not only all offences touching the royal forests were tried, but all persons living upon these properties governed. The Conqueror is said to have possessed 68 forests, 13 chases, and 781 parks. A chase is a smaller kind of forest, not subject to the forest laws, and which may be in the hands of a subject, whereas a forest can only be held by the crown. A park differs from a forest or chase in being of smaller extent and inclosed. The Conqueror, who is said to have loved the red deer as if he had been is said to have loved the red deer as it he had been their father, enacted very severe penalties against trespassers, and the killing of a stag or boar was visited with loss of sight. His successors were guilty of still greater cruelties, and it is said that to kill any of the beasts of chase within a forest was as penal as to kill a man. Vast tracts of country were depopulated in order to create new forests or to extend the limits of old ones, and under the colour of forest law the most cruel and horrid oppressions were exeraw the most crue and normal oppressions were exercised. At length, however, many of these hardships were removed by the carda de foresta, obtained in the 9th year of Henry III., the immunities of which, says Blackstone, were "as warmly contended for, and extorted from the king with as much difficulty, as those of the Magna Charta itself." It declares that "no man from henceforth shall lose either life or member for killing our deer; but if any man be taken and convict for taking of our venison, he shall make a grievous fine if he have anything whereof; and if he have nothing to lose, he shall be imprisoned a year and a day," and after that time, if he cannot find sufficient surelies, he shall abjure the realm. It also contains the following provision:—"Whatsoever archbishop, bishop, earl, or baron, coming to us at our commandment, passeth by our forest, it shall be lawful for him to take and kill one or two of our deer, by view of our forester, if he be present; or else he shall cause one to blow a horn for present; or else he shall cause one to blow a horn for him, that he seem not to steal our deer; and likewise they shall do returning from us as it is aforesaid." As this law is still unrepealed, any bishop or nobleman may shoot one or two of the deer, if he pass through a royal forest in going to correturning from parliament. By this charter, many parts which had recently been afforested were diseffected and stripped of their operations were united in the procession withingers, and reputations were made in the pressive privileges, and regulations were made in the regimen of such as remained. The forest courts were instituted for the government of the king's forests in different parts of the kingdom, and for the punishment of all injuries done to the king's deer or venison, to the of all injuries done to the king's deer or venison, to the vert or greensward, and to the covert in which such deer are lodged. These were (1) the court of attachment, ecodmote, or forty days' court, held once in every forty days before the verderers, to inquire into all offences against vert and venison; (2) the court of sucinsote, held thrice in the year before the verderers as judges, the swains or freeholders within the forest forming the jury, to receive and try presentments in all matters connected with offences against the forest least and to inquire into conversions and grissin an matters connected with onenees against the forest laws, and to inquire into oppressions and grierances committed by officers of the forest; and (3) the court of justice-seat, or supreme court, held every third year before the chief justice in eyre or his deputy, to hear and determine all treepasses within the forest and all plains of fearnings. forest, and all claims of franchises, liberties, and privi-leges, and all pleas and causes whatsoever therein arising. There was also what was termed a court of leges, and an example a so what was termed a court or regard, held every third year, for the lawing or expeditation of mastiffs, which was done by cutting off the claws and ball of the fore feet, to prevent them from running after the deer,—mastiffs being the only dogs that were permitted to be kept within the precincts of a forest. The principal officers of the forest were the

## Forestalling

many persons for alleged encroachments on the ancient boundaries of the forests, though the lands thus claimed had been in their possession for several centuries. This was one of the first grievances taken up by the Long Parliament; and an act passed by that assembly (16 Car. I. c. 16), which declared that the boundaries of every forest shall be those commonly known or reputed as such; and that no place where a justice-seat or other forest court has been held within sixty years, thall be accounted forest. Since the passing of that sot; the old forest laws have practically ceased. In Coke's time, there were sixty-mine royal forests, all of which, with the exception of the New Forest in Hampshire, erected by William the Conqueror, and Hampshire, erected by William the Conqueror, and Hampton Court Forest, by Henry VIII., were so ancient that no record afforded any information as to their commencement. The principal of these were the New Forest, Sherwood, Dean, Windsor, Epping, Dartmoor, Wichwood in Oxfordshire; Salcey, Whittlebury, and Rockingham, in Northamptonshire; Waltham in Lincolnshire; and Richmond in Yorkshire. During the present reign, several of the royal forests have been disafforested by act of parliament.

FORESTALLING, fore-stand'-ing (Ang.-Sax.), in Law is, by 5 & 8 Edw. VI. c. 14, described to be the buying or contracting for any merchandise or victual coming in the way to market; or dissuading persons from bringing their goods or provisions there; or persuading them to enhance the price when there. It is commonly associated with regrating, which is described by the same statute to be the buying of corn or other dead victual in any market, and selling it again in the same market, or within four miles of the place; and engrossing, or the getting into one's possession, or buying up, large quantities of corn or other dead victuals, with intent to sell them again; any of which practices were supposed to make the market dearer to the fair trader. Various subsequent statutes were pussed at different times against these alleged offences, until they were at length all repealed by 12 Geo. III. c. 71, on the preamble that, "Whereas it had been found by experience that the restraints laid by several statutes upon the dealing in corn, meal, flour, cattle, and other sundry sort of victuals, by preventing a free trade in the said commodities, have a tendency to discourage the growth and enhance the price of the same," &c. Unfortunately, however, they still remained offences at common law; and even as late as the year 1800, a corn-merchant of the name of Rusby was indicted for regrating thirty quarters of oats, at an advance of two shillings a quarter. It was not, therefore, till the passing of 7 & 8 Vict. c. 24, that forestalling, regrating, and engrossing ceased to be indictable at common law. This statute, however, does not affect the offence of spreading false rumours to enhance

able at common law. This statuto, however, does not affect the offence of spreading false rumours to enhance or decrease the price of goods, which is still punishable. FORFEITCHE, for fiture (Lat. forefactura, expulsion or outlawry), in Law, is a punishment by loss of lands, estates, offices, or personal effects, annexed to certain crimes, illegal acts, or negligence. Forefuture is two-fold,—of real and of personal estates. As to real estates, by attainder in high treason, a man forfeits to the king all his lands and tenements of inheritance, whether fee simple or fee tail, which he holds otherwise than as trustee or mortgages, and all his rights of entry on lands and tenements, which he had at the time of the offence committed, or at any time afterwards, to be for ever vested in the crown; and also the profits of all lands and tenements which he had in his own right for life or years, so long as such interest shall subsist. This forfeiture relates backwards to the time of the treason committed, yet it does not take effect unless an attainder be had; and therefore, if a traitor dies, or is killed before judgment is pronounced, it works no forfeiture of his lands. In felony, the offender forfeits all his chattel interests absolutely, and the profits of all estates of freehold during life; and after his death, all his lands and tenements in fee simple (but not those in tail) go to the crown for a year and a day, after which they escheat to the lord of the fee. These are all forfeitures of real estates, created by the common law, as consequential upon attainders by judgment of death or outlawry. The forfeiture of goods and chattels zecrues in every one of the higher kinds of offences,—in hightreson or misprision thereon; felonies

## Forgery

of all sorts, whether clergyable or not; self-murder, and a few others. In all these cases the personal estate of the offender of every description, whether in action or passion, or settled by way of trust, which he has otherwise than as an executor, or trustee, or mortagee, at the time of conviction, is forfeited to the crown. Lands are forfeited upon conviction. The forfeiter of lands has relation to the time of the fact committed, but that of goods and chattels has no relation backwards; but only such as a man has at the time of conviction are forfeited. Yet if goods be parted with collasvely, in order to defraud the crown, the law will reach time; but a bond fide sale of goods made by a felon or traitor between the commission of the offence and his conviction, is valid. Forfeiture in civil cases may take place under many circumstances. It may result from a breach of express conditions between two contracting parties, as between landlord and tenant, or from a neglect or refusal on the part of a tenant to implement the conditions of his tenure. Lands may also be forfeited by alienation contrary to law, as by conveyance to an alien, or by tortious alienation, as where the owner of a limited or particular estate conveys a greater estate than that which he himself possesses, as where a tenant for life assumes to convey the fee simple. Offices are forfeited by the neglect or misbehaviour of the holders, and the right to the next presentation to ecclesiastical benefices is forfeited by lapse.

Fonce, for (Ang. Noc.), the name of the apparatus used by a blacksmith for heating bars of iron and nammering them into the desired form: it is not unfrequently applied to the place in which the avocations of a blacksmith are carried on, being used in the sense of the word "smithy." It consists of a hearth in the

Fores, for (Ang. Nor.), the name of the apparatus used by a blacksmith for heating bars of iron and hammering them into the desired form: it is not unfrequently applied to the place in which the avocations of a blacksmith are carried on, being used in the sense of the word "smithy." It consists of a hearth in the form of a platform about three feet above the level of the ground, on which a fire of small coal is kindled for the purpose of heating the iron; a pair of large bellows, or a blowing apparatus, worked by a lever or treadle, being attached to it, by which the blacksmith is enabled to make the fuel on the hearth throw out an intense heat and glow. A trough filled with cold water is placed in front of the hearth, in which the heated iron may be cooled when it has been hammered into the shape required; and in addition to these, and hammers of various sizes, as well as rasps, drills, punches, and other instruments, the blacksmith is erovided with anvils on which he hammers the iron when it has been made red-hot. The centre of the anvil-head is flat, with pieces projecting from it at either end, one being made in the form of a wedge, on which the metal may be readily divided, and the other shaped like a cone, on which the iron may be bent into a curved or circular form. The forges in which auchors are made are provided with larger and more powerful instruments; but the shanks, arms, and flukes of large anchors, intended for men-of-war and merchant-vessels of considerable tomage, are welded together by means of Nasmyth's hammer, a contrivance that is worked by steam-power. (See Nasmyth's Hammer, by mending the process more rapidly. One of these—Campbell's steam-forge-siz worked by steam-power. (See Nasmyth's steam-forge-siz worked by steam-power. (See Nasmyth's steam-forge-siz worked by steam-power. (See Nasmyth's steam-forge-siz worked by samall engine, as its name implies, which is attached to the faceted by a combination of wheels, shafts, and levers, attached to a blowing apparatus, and various hammers an

general principles of construction and the manner in which the motive power is applied.

Forger, for-je-re (Lat. crimen falsi), is defined to be "the fraudulent making or alteration of a writing to the prejudice of another man's right." By 5 Eliz. c. 14, to forge or make, or knowingly to publish or give in evidence, any forged deed, court-roll, or will, with intent to affect the right of real property, either freehold or copyhold, was punishable by a forfeiture to the party aggrieved of double costs and damages;

869

by standing in the pillory, and having both his ears out off, and his nostrils slit add escared; by forfeiture to the crown of the profits of his lands, and by perpetual imprisonment. As commerce increased, and when paper credits were established, various statutes were passed inflicting capital punishment on the forging, altering, or uttering as true when forged, bank-bills, notes, or other securities, bills of credit, &c.; so that in Blackstone's time, as he says, there was "hardly a case possible to be conceived wherein forgery that tends to defraud, whether in the name of a real or fictitious person, is not made a capital offence." But by 11 Geo. IV. & 1. Will. IV. c. 68, the statutes concerning this offence were consolidated, and, after long and reiterated discussions, the punishment of death was also abolished in all cases, except for the forgery of wills and bills of exchange. Finally, by 2 & 3 Will. IV. c. 123, and 1 Vict. c. 84, the punishment of death was abolished for all kinds of forgery, and a punishment varying from transportation for of death was abolished for all kinds of forgery, and a punishment varying from transportation for life (now penul servitude) to imprisonment for one year, according to the nature of the offence, substituted. It is by no means necessary to constitute atorgery, that the name of any person be counterfeited, though this is the most common mode in which it is effected; for any material alteration, however slight,—as the ante-dating of a deed, is as much a forgery as the other. Even if the name subscribed be a fictitious one, but appended for the purpose of deceiving a one, but appended for the purpose of deceiving, a forgery has been committed. The offence is complete by the making the forged instrument with a fraudulent intent, though it be not published or uttered. consists in the fraud or deceit.

consists in the iran or decet.

FORENT-MR-NOT. (See MYSSOTIS.)

FORK, fork (Sex. forc), a common instrument, consisting of a handle and a blade, the latter of which is divided into two or more prongs, used generally for the table. The table-fork did not come into active use the table. The table-fork did not come into active use in England until the reign of James I., and then it was introduced from Italy. Ben Jonson, in "The Divellis an Asse" (act 5, scone 4), makes one of his characters, Mere Craft, speak of his "pains at court," to get a patent for his project for "the landable use of forks, brought into custom here as they are in Italy, to the sparing of naphins;" and also that the forks are to be "of gold and silver for the better personages, and of steel for the common sort." We may therefore date their use in England from the latter end of the 17th, century. The agricultural or dung-fork is used for the century. The agricultural, or dung-fork, is used for the purpose of lifting manure and rubbish.

FORLORN HOPE, for lorn' hope (Sax. forloren, left without resource; hopa, hope), in Mil. tactics, this term signifies a desperate case. A detachment of men, serin signines a desperate case. A detachment of men, generally volunteers, from different regiments, are selected to assault a breach, or other position of danger, without which a town could not be taken; and this is termed taking a forlorn hope. The taking of the Cashmere gate, at the siege of Delhi, in the year 1837, may be mentioned as an inclusion of a few countries. 1857, may be mentioned as an instance of a forlorn

hope successfully redeemed.

FORM, form (Lat. forma, Fr. forme), is the manner and mode in which anything is presented to our ideas of conception. In Phys., the shape and external appearance of a body, the figure of the same as defined by angles or lines, or that manner of presenting itself to the eye peculiar to different bodies, is termed form; as, form of a circle; form of a square; the form of the human body; and other instances. Form is likewise to be of a circle; of one of square; the form of the adman lodg; and other instances. Form is likewise to be distinguished from the real apparent nature of things; and if we take it in this light, the idea of form is used in a practical manner in our daily speech and scientific pursuits.—In Law, form is applied to a rule to be observed in legal proceedings. We also use the terms, form of rhetoric, form of government, beautiful form, come of rhetoric, form of government, beautiful form, come of the form, account of the southern hemisphere, and disposed into columns, &c., locked up in a chase ready to receive an impression. Whoever esteems the form of a thing more than the thing itself, through narrowmindedness, is considered to be a formalist.

FORMA PAUPERIS, forf-mil paw'-pe-ris (Lat., in the form or condition of a poor person), in Law, by statute 11 Henry VII. c. 12, every poor person that is such as will swear that he is not worth five pounds, shall have

original writs or subparas gratis, and counsel and attorney assigned to him without fee; and is excused from paying costs when plaintiff, by the statute 23 Henry VIII. c. 16, if unsuccessful; but, according to Blackstone, it was formerly usual to give such paupers, if nonsuited, their election either to be whipped or pay the costs. A pauper, however, in the event of success, may recover costs, though he pays none; but this only by order of the court or judge; for the counsel and clerks, though bound to give their labour gratis to him, are not bound to do so to his antigonist, tuless he, too be a pauper. To prevent trifling or malicious actions, various extractions are not bound to do so to his antigonist, tuless he, too be a pauper. be a pauper. To prevent trifling or malicious act various restrictions are made regarding the costs.

FORMEDON, for-me-don (a corruption of the two Lat, words formam doni, according to the form of the gift), in Law, was an old form of action, which was in the nature of a writ of right, and was the highest action the tenant in tail could have. As a tenant in tail could not have an absolute writ of right, which was confined not have an absolute writ of right, which was confined to such only as claimed in fee simple, this writ of formedon was granted to him by the statute de Donis. This writ was distinguished into three species,—a formedon in the descender, in the remainder, and in the reverter, according to the estate of the party who sued. This, with many of the other old forms, was abolished by 3 & 4 Will. IV. c. 27.

FORMIO ACTD, for-mik (in Chem.), HO.C. HO., spec. grav. at 329, 12227. This acid derives its name from the circumstance that twas first obtained from distilling the Formica graft, or red ant. which

name from the circumstance instact was first obtained from distilling the Formica rafu, or red ant, which, when irritated, ejects an acid liquor. It is a burning liquid of an irritating odour. It is exceedingly corresive, producing a sore if dropped on the skin. Below 32° it crystallizes in brilliant scales. It boils at 221.5°, 32° it crystallizes in brilliant scales. It boils at 221°, yielding au inflammable vapour burning with a pale blue flame. Formic acid is easily obtained by mixing, in a large retort, one part of starch, four of binoxide of manganese, and four of water. Four parts of sulphuric acid are then added, and when the maxture has ceased frothing, it is distilled, and yields a weak impure acid, which is neutralized with carbonate of load, and re-distilled with an equivalent of sulphuric acid. With acid, which is neutralized with carbonate of load, and re-distilled with an equivalent of sulphuric acid. With the metals, formic acid forms a series of soluble salts, called formiates. Although an organic product, formic acid has been formed by synthesis by Berthelot.

FORMICA, for-mi-ki (Lat.), a gen. of insects belonging to the fam. Formicide, and distinguished by having the footstalks of the abdomen composed of a single joint, the mandibles triangular, and denticulated at the edges.

(See ANT.)

FORMULA, or FORMULARY, for mu-la, for mu-la-re (Lat.), is a rule or model, or certain terms prescribed (Lat.), is a rule or model, or certain terms prescribed or decreed by authority, for the form or manner of an act, instrument, proceeding, or the like. The Roman law was full of formulas. In clurch matters a formula is a profession of faith; in medicine it denotes the constitution of medicines, either with respect to their prescription or convisions. scription or consistence.

scription or consistence.

Termula, in Chom., is an expression of the composition of a substance by means of symbols. The formulæ of bodies may be either empirical or rational. An empirical formulæ is one giving the elements contained in a body, without reference to their arrangement. For instance, the empirical formulæ of crystallized sulphate of copper would be CuO\_SH<sub>3</sub>, but the rational formulæ, showing its composition, would be CuO\_SO\_5mq. Formulæ are the most convenient way of expressing the decompositions taking place when certain substances are mixed, a few lines of symbols serving for pages of explanation.

## Forthcoming

erected on the sea-coast, for the defence of certain positions, and are garrisoned by a small body of troops.
Although they do not inclose a space of any great ex-Attnough they do not induce a space of any great of the tent, yet they are strongly constructed, and, being placed in commanding situations, often form an important line of defence. They are generally quadrilateral, tant the or detence. They are generally quantinaters, with hastions or demi-bastions at the angles; but it depends mainly on the position they occupy, whether they are triangular, equate, polygonal, or in the form of a crow-work or star. They consist for the most part of a rampart, surrounded with a ditch and glacis; but in some cases an outwork is constructed for the but in some cases an outwork is constructed for the defence of any side on which it may be more easily assailed. Paris is completely girdled with a chain of carefully-planned forts, mostly pentagonal, in the shape of the enceinte, and situated at distances varying from a mile to 2½ miles from the inner line of hastions that encircles the city. Cherbourg may also be cited as an example in which a town is effectively protected from attack by sea or land by a chain of detached forts and redoubts, which is doubled on the conthagent side of the town. south-west side of the town.

FORTHCOMING, in Scots law, is a form of action by which the subjects of an arrestment are made available to the arrester. In an action of forthcoming, the arrester cites the party in whose hands the goods or debts are arrested, to appear before the judge, who, on hearing parties, orders the debt to be paid, or the effects to 18 delivered up to the arresting creditor.

FORTIFICATION, for-tif-e-kui-shun (Lat. fortis, strong, and facere, to make), in Mil., the art of constructing works of defence and offence for the protection or reduction of any important town or position. Such works are always planned by the military engueer, and carried out under his direction and superintendence. They are commonly divided into two intendence. They are commonly divided into two classes, respectively known as permanent fortifications and field works. Under the former all works are included that are constructed for the defence of a town, harbour, arsenal, dockyard, &c., being carefully laid out and built with a view to durability and the resistance of an attack, whenever it may be made; while under the latter, all works are classed that are intended to serve a temporary purpose; such as siege-works and batteries for an attack on a fortress, or lines of intronohment hastily thrown up for the protection of an army in the field, or to check the advance of an enemy an important strategical position. These works on an important strategical position. These works differ mainly in the manner in which they are built, the ramparts and parapets of permanent works being faced or revetted with blocks of granite; the terreplein of the rampart on which the guns are worked, the cheeks of the embrasures, casemates, bomb-proof buildings for magazines, &c., being formed of the same material; while field-works consist of mounds of earth formed of that which is thrown up out of the ditch in front, having the ramparts and embrasures revetted with sods of turf, fascines, gabious, and sand-bags, the terre-plein for the support of the guns and their carriages being made of pieces of thick timber strongly bolted together. To glunce briefly at the history of the rise and progress of the science from the enriest ages to the present time. The existing system of fortification doubtless found its origin in early ages, in the formation of a mound and trench round any small collection of dwellings, for the purpose of affording the inmates and their possessions some protection from the attack of a maranding foe; a gate being made in one part of the rampart for the ingress egress of those that dwelt within it, with a mov-bridge for the nassage of the ditch. This method able bridge for the passage of the ditch. This method was pursued by the Gauls and Britons in the time of was pursued by the Gauss and Britons in the time of Cassar; and they added strength to the earthen mound by throwing it up against a stockade of stout stakes or piles, which were driven into the earth in close proximity to each other, and interwoven with boughs and branches of trees. The field-works of the Romans were as effective as the permanent fortifications of the savage tribes of Central and Western Europe, remaining in many parts of England to this day, as a testimony to the skill of the Roman soldiers in fortifying

### **Fortification**

disposed round the camp, in the form of a circle, and strengthened by an abbatis, or barrieude, formed of the branches and trunks of trees. At a very early period stone walls of considerable breadth and great period atone walls of considerable breadth and great strength took the place of the simple rampart of earth, for the defensive works thrown up around "fenced cities;" and these were furnished with battlements and machicolations (see MACHICOLATION) for the protec-tion of the archers that manned the walls, and as a means of aunoying the besiegers who might attempt to undermine the rampart. The spaces between the battlements, and the battlements themselves, were subsequently modified into the parapet-wall and em-bracures, as we now have them, on the introduction of cannon. Examples of early fortifications are to be found in the remains of the Cyclopian walls that once found in the remains of the Cyclopian walls that once surrounded the old Greek cities of Tiryns and Mycense. The Phoenicians are said to have been the first who The Phonicians are said to have been the first who regularly fortified their cities with stone walls; bit, however this may be, it is certain that the cities of Rypt, and the great cities of Asyria,—Babylou and Nineveh, were girdled with fortifications of marvellous strength and size, on which several chariots could be driven abreast of each other. Until the year 1500, the characteristics of the defensive works of a town were nearly the same in all countries: first, they consisted of a lotty and massive polygonal wall of great thickness, with a fawse-braye, or bank of earth, thrown up in a sloping form against the exterior, to protect it from the attacks of the battering-ram. Then towers were added, in the form of large square or semicircular buttresses, projecting from the angles, and also from the face of the wall in various parts, which enabled the defenders to enfilade that portion of the wall which lay between any two of them, and so defend it in a more effectual manner from the attacks of assailants who sought to make a breach at its base with their engines of war. These flanking towers were the origin of the modern bastions. Cutworks were then constructed beyond the ditch, opposite to the different entrances to the town, for the better protection of the gates, connected with the main works by drawbridges. While this disposition of the wall, and its various parts, may be traced in all the fortifications of ancient cities, and those of the towns and castles of the middle ages, and those of the towns and castles of the middle ages, so it may be seen more fully developed in the curtains, bastions, crown-works, and bridge-heads of the fortifications of modern times. The old method of construction was efficient enough as long as battering-rams, scaling-ladders, and similar engines, formed the chief means of attack, and javelins and arrows the most formidable projectiles that could be showered on the assailants by those who manned the walls; and although the introduction of the inextinguishable Greek fire, in the 7th century, as a missile that although the introduction of the inextinguishable Greek fire, in the 7th century, as a missile that brought death, terror, and destruction in its train, blazing flercely even under water, and injuring everything wherever it fell, with the exception of stone walls, yet no modifications of the principles of construction were found absolutely necessary until the invention of cannon, which followed closely on that of gunpowder, in the 14th century, directed the thoughts of the soldier-architects of the succeeding cycle to seek means whereby the new weapon might be made as means whereby the new weapon might be made as efficient for the protection of the walls, by a proper disposition of the faces of the works with reference to each other, as it was effective in causing breaches in the ramparts, that rapidly crumbled under the crushing shock of the heavy balls of stone and iron that were hurled point blank against them. The result was the hurled point blank against them. The result was the introduction of bastions of the present form, instead of the old flanking towers, projecting from the corners of the work in salient angles, the rampert forming four sides of an irregular pentagon, the fifth, or gorge, being left open as a communication between the bastion and the interior of the fortress. But the chief fault of the old flanking towers was equally perceptible in the new bastions: they were still too small, and too far apart, to defend each other in an efficient manner; and the mlatforms or terre-pleins of the majority were not platforms or terre-pleins of the majority were not calculated for the reception of artillery of any size. Towards the end of the 16th century, an attempt to remedy this defect was made by Errard de Bar le Duc, even temporary camps, and the great strength of their even temporary camps, and the great strength of their works. But the field-works of the Gaule and Britons a French engineer, who introduced considerable improvements into the received methods of constructing

fortifications. He made the faces of his bastions much longer, and the curtains connecting them much shorter, than they had hitherto been; but the faces of the bastions terminated at the shoulders in orillors, or pieces of the rampart in continuation of the face, which we have the shoulders in the face, and the shoulders in the sho pieces of the rampart in continuation of the face, which were in the form of an are, and entered towards the interior of the bastion; and his flanks, which were bereft of their due proportions by the orillons, were disposed at an angle of 80° to the curtain, which would inevitably bring a fire of muskerry, directed from the flank at right angles to its face, on the defenders occupying the opposite extremity of the curtain. De Ville, an engineer who flourished about 1630, lengthened the

> FORTIFICATION. REGULAR ő SECTION VERTICAL

flanks, and constructed them at right angles to the curtain; but a still further advance to the present sys-tem was made about fifteen years later, by Count Pagan, who constructed the faces of his flanks in lines perwho constructed the races of his hanks in lines per-pendicular to the faces of the collateral bastions pro-duced, which caused them to splay outwards from the curtain in such a direction, that a fire directed per-pendicularly from the faces along their entire length would enfilade the faces of the collateral bastions, and

flanks to his bastions, which were parapets parallel to the faces of the outer flanks, rising above one another in tiers towards the interior of the bastion. It remained for Vanbas to give a systematic method of constructing regular fortifications, which he effected by taking fractional parts of the length of the side of the polygon within which the exheinte was formed, and which was bounded by lines drawn to join the salient angles of the hastions, which indeed, were coincident angles of the bastions (which, indeed, were coincident with the angles of the polygon, as far as their vertices were concerned), to furnish the dimensions of various pages of the work. As this is the foundation on which all other systems are based which have been introduced since Vauban's time, and as a knowledge of it is required from all candidates for commissions in the army, a detailed account of the method of constructing a regular front of fortification, in accordance with that engineer's first system, will be presently given. All modern systems of fortification, though they differ in many noints of detail yet arree in the essential angles of the bastions (which, indeed, were coincident All modern systems of fortineation, though they duter in many points of detail, yet agree in the essential parts. "In order to explain these systems, it will be convenient to consider them first without reference to their form, or the position of the ground-lines in respect to each other, but merely as defences against an army with artillery advancing directly in front. In the accompanying figure we show a vertical section of a regular fortification on the ground-line XY, the a regular fortification on the ground-line XY, the place to be defended being supposed to be between X and A. The mass of earth A:BCDEFGH forms the rampart with its parapet. AB is the interior slope of the rampart; BC is the terre-plain of the rampart, having a breadth of about 40 feet, on which the troops and cannon are placed; DE is called the banquette, or slip, on which the soldiers mount to fire over the parapet. EFG is the parapet of a height over the parapet; EFG is the parapet, of a height (about seven feet) sufficient to protect the men and game on the terre-plein, and sloped in the direction FG towards M, the opposite side of the direction FG towards M, the opposite side of the dick, so that a man approaching there may be seen and fired at; GH is the exterior slope of the parapet; and I is the recetment, or wall of masonry supporting the rampart, and strengthened by buttresses placed at small intervals behind it. This must be of sufficient height to prevent its being easily scaled, but yet must not rise higher than the edge of the exterior work at Q, in order that it may not be seen and breached by distant batteries. The exterior front of the rampart. distant batteries. The exterior front of the rampari, covered by the revetment (HK), is called the escary; IK LM is the ditch, the dimensions of which will be determined by the nature of the ground, but must be such in general that its excavation, or debtai, must produce sufficient earth, or remblai, to form the rampart; the opposite side of the ditch (LM) is the counterscarp, also supported by a revetment of masonry; MN is the consered way, a space of about ten yards in breadth, having a banquette (NOP), and protected by a parapet (PQ), the superior slope of which (QR) is called the glacis. The use of the covered way is to allow troops to be drawn up unseen by the besiegers for the purpose of making sorties; by the besisgers for the purpose of making sorties; it also enables the garrison to keep a closer fire upon the approaches of the enemy, and its parapet forms a strong protection to the revetment of the rampart." —(Brande's Dictionary, from which we also borrow the accompanying woodcut.) Colonel Bruce Hamley, in his admirable work entitled "The Operations of the War explained and illustrated," thus expresses his views relative to fortresses:—"At the period when the system of making war was so far organized as to render armies extremely dependent on their bases, but while they were still unwieldy machines not only easily divided and slow of movement, the establishment of great fortresses on frontiers liable to invasion, and on main roads leading from those frontiers to the capital, was an obvious expedient; for these slow-moving bodies could not venture to penetrate within a line of strong places, exposing to the sallies of powerful garrisons the long communications and cumbrous convoys which they did not possess sufficient mobility to defend by pendicular to the faces of the collectal nations pro-duced, which caused them to splay outwards from the curtain in such a direction, that a fire directed per-pendicularly from the faces along their entire length would enfilled the faces of the collateral bastions, and prevent an attacking party from effecting a lodgement in the ditch. He also constructed double and triple

country. They are expensive to construct and expensive to maintain. A few of them will swallow up for their necessary garrisons armies that might turn the scale in the open field. Hence it was only necessary to show that invading armies could pass them, and, after victories in the field, could make of them an easy and certain prey, to render it apparent that a continuance of such a system of defence must be a costly blunder. Forhaps the rudeness of vehicles and the backness of all but great roads, may have combined with the cumbrous organization of the armies of the last century, to render them little capable of passing such fortresses as lay in or near their path. But when such fortresses as lay in or near their path. But when roads and transport improved, and armies underwent roads and transport improved, and armies underwent a change, these mobilized machines, avoiding by a slight detour the fortified places in their way, leaving corps complete in their separate organization to observe or blockade them, and rendering themselves to some extent, independent of convoys by contributions raised within the enemy's frontier, marched upon those points of the theatre that were of greatest strategical importance, seized them, defeated and ruined the hostile armies, and then at their leisure reduced or demanded from the prostrate power the cession of the stronghold in which it had so vainly confided." Thus it was that the single victory of Marengo gave to Napoleon the fortresses of Genoa, confided." Thus it was that the single victory of Marengo gave to Napoleon the fortresses of Genoa, Coni, Alessandria, Cottona, Arona, Piacenza, Cera, Savona, and the citadel of Milan; thus it was that during the memorable seven weeks war, during which the Prussians broke the power of her Austrian rival, she pushed on regardless of the strong places held by her enemy; these fortified positions being rendered almost powerless to inflict mischief, after the defeat of the Austrian forces in the open field. At Plate LVII., fig. 1, we give a drawing of a fortified place. The names of the works are as follows:—a, glacis or declivity; b, covered way; c, counterscarp; d, single tensille; c, double tensille; c, tensille in the ditch; f, horn-work; g, places of arms; h, the most or ditch; f, horn-work; g, places of arms; h, the most or ditch; ravelins; k, half-moons; l, crown-work; m, bonnet 7, norn-work; 3, places of arms; 3, the hotat of ditch; 2, ravelins; 4, half-moons; 6, crown-work; 3, honnet or priest's cap; 3, counterguard; 5, bastions; 5, bastions with circular fluths; 9, curtain; 7, rampart or wall; 8, bridge. The names of the approaches are: 1. trenches of approach; 2. lines of communication; 3. batteries; 4. forts for defence of the trenches; 5. a sap; 6. a mine. At Plate LVIII. we exhibit the whole plan of a place besieged: A, H are the bastions; C, the ravelin; D, line of communication of the attacks; E, first parallel; F, second parallel; G, third parallel; H, the approaches; I, places of arms; K, square redoubts to prevent sallies; L, traverses in the third parallel; M, batteries (a, cannon, b, mortare); N, glace; O, places of arms in the covered way; P, the ditch; Q, bridge of communication; R, a river; S, rising ground. Figs. 2, 3, 4, Plate LVII., display the various ways of mounting guns in the works of a fortified place. Vauban also improved the construction of the ravelin, and was the first engineer who introduced ricochet firing on attacking a fortress. who introduced ricochet firing on attacking a fortress. He also formed traverses in the covered way, to protect the besieged from this kind of firing, and the places the besieged from this kind of fring, and the piaces of arms at the salient and re-entering angles of the covered way. It will be understood, in the construction of works one in advance of another, that the reliefs of the different ramparts, on their heights one above another, must be sufficient to allow of a fire of musketry being kept up from the crest of the parapet of a lower work, while a cannonade is being directed example the army to their size-works from the rem. against the enemy on their siege-works from the ram-parts of the works above, without injuring the men in the work below. Thus the soles of the embrasures in the faces of the ravelin should be in a horizontal line that is, at least, four feet above the crest of the glacis, and the tenaille should be low enough to allow a muskerry fire from the flanks of the bastion, glacis, and the tensille should be low enough to allow a musketry fire from the flanks of the bastion, and the intervening curtain to pass over the heads of its defenders. The Dutch engineer Coehean was contemporary with Vanban, and constructed the fortifications of most of the principal towns of Holland and Belgium. His system is very similar to those of Vauban; but it is distinguished by the introduction of large orillons, formations. He also constructed works of great strength in the immediate vicinity of important harbours distinguished by the interduction of large orillons, formations. He also constructed works of great strength in the immediate vicinity of important harbours the interior of the bastions, as well as in front of them;

and redoubts in the interior of the ravelins, which pro-tected his curtains. About 1740, Cormontaigne, a Frenchman, introduced a system founded on Vanban's, in which he extended the faces of the ravelin in front of in which he extended the faces of the ravelin in front of the curtain, diminishing the extent of the salient angle formed by them. He also formed retrenchments in his bastions, and made the re-entering places of arms in the covered way large enough to admit of the construction of redoubts, having the main ditch immediately in their rear. These were useful in adding to the means of defending the covered way, and they also protected the openings that appear between the extremities of the tensile and the flanks of the bastions, on either side of it. Various additions and modifications of these systems have been introduced from time tions of these systems have been introduced from time to time, by English, French, and German engineers, since 1750. In the present century, however, the most remarkable is the new system, introduced by the Frussians, of surrounding the place with a polygonial execute without beations, and protecting them by flank fires from works resembling caponnières, projecting at right angles from the main walls at the centra of each side of the polygon, so that the guns of the caponnière flank the caponnières, while those of the caponnière flank the execute. The head of the projecting work is protected we require the faces of the projecting work is protected. tions of these systems have been introduced from time enceinte flank the caponneres, while mose of the caponnière flank the enceinte. The head of the projecting work is protected by a ravelin, the faces of which can also be enflished from the enceinte by guns placed in casemates cut in the proper direction. In the stege of Sebastopol, the Russian general Todleben, one of the most skilful engineers of modern times, employed large earthworks with singular success for employed large earthworks with singular success for the protection of the town. (See EARTHWORKS.) The idea of substituting earthworks for stone fortifications has also been warmly supported by Mr. Fergusson. It is not improbable that the great improvements that have been lately effected by Sir William Armstrong and Mr. Whitworth in the construction of guns of heavy calibre, will lead to an inquiry into the form of structure and kind of materials best calculated to resist the shock of the heavy weight of metal that the breaching guns of the present day can launch against the walls of a fortess. With regard to the general plan of constructess. the present day can launch against the wans of a construc-tress. With regard to the general plan of constructrees. With regard to the general plan of construc-tion, whatever may be the new theoretical principles for works of defence that may be broached by modern engineers, it seems necessary, when we consider the great superiority of the guns that would now be used great superiority of the guns that would now be used in a siege over the Lancaster guns and other heavy ordance that were brought into position before Sebas-topol, as lately as 1854-5, that all existing fortifications based on Yauban's systems should be strengthened by a judicious combination of exterior works, in order to a judicious combination of exterior works, in order to enable their defenders to prolong their resistance to the utmost, if not with complete success. That the English government are fully alive to the necessity of doing this, is manifest from the additional fortifications that are being constructed about Plymouth, Portsmouth, Pembroke, Chattam, Sheerness, Portland. Dover, Cork, and other places, for which an expenditure amounting to nearly ten millions sterling has been sanotioned by parliament.—Ref. Straith's Treatise on Fortification; Macauley's Field Fortification; Adde Mémoirs to the Military Sciences; Brande's Dictionary of Arts and Sciences; art. "Portification," in Encyclopadia Metropolitana.

FORTITUES, for-t-stude (Lat.), is one of the virtues termed cardinal. It may distinguish itself actively by resolution or constancy in adhering to duty in the face of difficulty and danger which cannot be avoided, or

resolution or containty in antering to duty in the lace of difficulty and danger which cannot be avoided, or by courage or intrepidity in maintaining firmness and presence of mind in the midst of perils from which there may be escape. Fortitude displays itself passively in enduring with patience, submission, and resignation whatever misfortunes one may be called upon to suffer.

#### **Portunatus**

tresses on the south coast; considerable additions having been made to the fortifications that surround these, as well as other places of importance, since the completion of the works at Cherbourg. There is no inland fortress in Great Britain; but when the subject of the coast defences was brought before parliament in 1859, the formation of a strong fortress at Cannock Chase, in Paffordshire, was auggested, in connection with large government works for casting artillery and the manufacture of firearms.

Fortunatus, for the manufacture of firearms.
Fortunatus, for the mail that, is the title of one of the best German Volksbücher (people's books) ever written, and which has been translated into perhaps every language of Europe. It originated in the 15th century, though many of the tales included in it are of much older date. The oldest printed edition of the book now extant was published at Fraukfort in 1509. The story is, that Fortunatus and his sons are the possessors of an inexhaustible purse of gold and a wishing. sory is, tast rectificates and his sons are the possessors of an inexhaustible purse of gold and a wishing-cap, which, however, in the end, prove their ruin. Thomas Decker made it the subject of his "Pleasant Comodie of Old Fortunatus" (1600); and Tieck gives the story in his "Phantasus" (3 vols., Berlin, 1816).— Ref. Ersch und Gruber's Encyklopadic, 1 sect., vol. 46.

Mef. Ersch und Gruber's Encyklopadic, 1 sect., vol. 46. Forum, fore'um (Lat. forum, a market), the nape given to an open space in Roman citics, generally surrounded by a covered colonnade, that formed an ambulatory, and buildings of various kinds, such as temples, courts of law, prisons, granaries, &c. In the later period of the empire, when Rome had attained the summit of its glory, there were nineteen forw within its limits, which were divided into two classes, some being especially set, apart for public meetings. within its limits, which were divided into two classes, some being especially set apart for public meetings and the proceedings of the law couris, while others were devoted to business purposes and the requirements of trade. The Forum Romanum, the first that was creeded in Rome, served equally for the purposes of trade and all public meetings, as well as for the administration of justice by the consuls, decemvirs, and other magistrates of Rome. This forum was subsequently distinguished for its magnificence; the short were removed and meant remove of the bother. shops were removed, and many temples of the heathen gods, the senate-house, and the comitium, were erected in its immediate vicinity, and in communication with it. It was also adorned with arches, statues, and pulpits, from which public meetings were addressed, and which were called rostra, from being surrounded, with the brazen beals (rostra,) or ornaments of the prows of the ships of war that had been captured by the Roman triemes. Exhibitions of gladiators were often shown in the forum. The Roman forum corresponded to the agora of the Greeks, and no Roman city or colour was without this important centre for shops were removed, and many temples of the heathen sponded to the agora of the Greeks, and no Roman city or colony was without this important centre for the transaction of business and public affairs. Plans of the forum at Pompeii and the principal forum of Rome are given in "Pompeii," a work published by the Society for the Diffusion of Useful Knowledge.

Fossz, or Foss, fos (Fr. fosse, a ditch; from Lat. fodio, fosses, I dig), a term in Fort. applied to a ditch, generally filled with water, encircling the rampart of a fort, lying between the scarp and the counterscarp.—In Aunt., the term is applied to a large cavity in the bone, with no exit or perforation.

Fosszi, fww-sil (Lat. fossus, dug up), in Geol., the body, or any portion of the body, of an animal or plant buried in the earth by natural causes, or any recognizable impression or trace of such a body or part of a

nizable impression or trace of such a body or part of a body. Such is the definition given by Mr. Jukes, one of the most philosophical geologists of the present day. The old geologists used to include minerals, or any other distinct bodies that were found in rocks, under the term of fossils. According to modern views, foseils are simply organic remains, allowing the word "remains" to apply even to foot-prints and other transient impressions. A fossil is not necessarily a petrifaction. Some fossil shells found in comparatively petriaction. Some lossification of nonparticely old rocks, such as the soft compact clays of the colitic series, are less altered from their living state than many shells included in recent coral reefs. Wood, again, may be found in such rocks still soft and but little altered; while in much more recent formations

## Foundation

of a small mine. It is made by sinking a pit about ten or twelve feet below the surface of the ground, and putting a wooden case at the bottom, containing several pounds of powder, and occasionally some shells. It was formerly fired by means of a saucisson, a long narrow beg of lines filled with powder, which was pro-tected from injury likely to arise from the dampness of the ground by inclusing it in a casing of word. The of the ground, by inclosing it in a casing of wood. saucisson communicated with the fougass at one end, while the other was brought in a shallow trench under the earth to any point from which the train might be conveniently fired. Fougasses are generally made in the glacis of a work, to throw the attacking party into confusion when an attempt is made to take the work by storm. A very destructive kind of fougass is made by filling the hole that has been excavated to receive the powder with rough stones as well as earth. In modern warfure, fougasses are exploded by means of the electric spark and by detonating powder, with which wires communicate that are laid in the path by which the assailants advance to the attack. Fougasses that were contrived to be exploded by wires attached to them were found in the Russian works before Sebastopol at the termination of the siege and the occupa-

tion of the town by the allied forces.

FOUNDATION, foun-dai'-shun (Lat. fundatio), the name applied to the surface of the mass on which any superstructure is reared. Foundations are of two kinds.—natural and artificial: but of whichever class the foundations may be on which a building is to be raised, care must be taken by the architect, or builder, to ascertain that there are no existing causes which would render them liable to lateral displacement, whatever may be the weight of the materials that are piled upon them. Rocks, gravel, loamy soil, and clay, are equally available for natural foundations, provided that there be no causes, arising from the position of the strate or from the presence of water underneath, that may tend to produce natural displacement; but the thickness of the lower part of the walls of the building must be in accordance with the nature of the foundations on which the building is erected,—a greater breadth being required for walls on foundations of loam or clay, than for those which are raised on rock or gravel, as the former soils are more susceptible of compression than the latter, and require the footing of the walls that are built on them to be spread out to a the walls that are built on them to be spread out to a greater extent, that n larger area of bearing-surface may be secured. Artificial foundations, on soft, compressible soils of great depth, such as the alluvial deposits at the mouths of tidal rivers, loose shifting sand, and peaty togs, are formed in various ways. One method is to drive in a number of large piles vertically that are of sufficient laurable to a traver and become One method is to drive in a number of large place vertically, that are of sufficient length to enter and become fixed in a substratum of a harder and less-yielding nature. These piles, in some cases, support the entire weight of a building, as columns support a roof; in others, they render the soil into which they are driven more solid, by pressing the earth that is between them more tightly together, and therefore more capable of bearing the heavy weight of any superstructure raised upon it. After the piles have been driven in, bulks of timber are laid transversely across the heads, like sleepers, and the whole is firmly bedded in a mass of concrete, which affords a hard and level platform for the masonry that is to be placed upon it. Sometimes iron tubes are forced into the soil, which are afterwards iron tubes are forced into the soil, which are afterwards filled with concrete; or, when it is practicable, piles of swood or iron are driven in closely together, so as to inclose a space with a close shecting, and the soil in the interior is removed, and replaced by a mass of concrete and rubble. In forming foundations in sand for the piers of bridges, &c., tubes of brick-work, like the linings of wells, are formed and sunk in the same way (see WRIL-SIMING), and the interior is afterwards filled with concrete. In securing foundations for some of the bridges and railway-bridges in various parts of England and France, among which may be named the Royal Albert Vinduot at Salkash, iron tubes of great size were such through the loose soil until the solid rock at the bottom was reached. In peat bogs, large square little attered; while in much more recent formations is the bottom was reached. In peat hogs, large square it is entirely mineralized, and converted either into entirely mineralized.

#### **Foundations**

Laucashire. In all artificial foundations, when timber piles and concrete are used, the engineer has to look carefully to the nature of the materials at his command, and to consider if any change is likely to take place in the normal condition of the soil in which his foundation is made, by subsequent drainage or other causes. For a constant state of moisture, beech and elm afford the best timber for piles; but when the substructure is likely to be drier at some periods than at others, or, in other words, to be exposed to alternations of dryness and moisture, then pine is better that

other words, to be exposed to alternations of dryness and moisture, then pine is better than either of the kinds of timber that have been already named.

FOUNDATIONS, in Pol. Eco., are institutions established and endowed, usually by private individuals, for the promotion of some useful or benevolent purpose. During the middle ages, it was very common to bequeath property for various religious or scholastic purposes. The two great universities of England,—Oxford and Cambridge, owe their existence mainly to this source, as do also the greater number of the gray. this source, as do also the greater number of the grammar and free schools throughout the country. Numerous hospitals have also been established in this way, and various other institutions for the relief and assist-

ance of the poor.

FOUNDING, found'-ing (Fr. fondre, to cast metals, &c.), the term generally applied to the process of producing any article by causing moltan metal or plaster of Paris to ren in a liquid state into a mould of the requisite form, which is made in various ways, and of substances best suited for the reception of the liquid material that is to be poured into it. The process is applied to the manufacture of articles in iron, bronze, bell-metal, lead, steel, copper, porcelain, plaater, and cement of various kinds. The method of founding or casting cannons in iron and bronze will be found elsewhere (see Cannon), and as the process adopted in casting statues in plaster, and making ornamental pottery and busts in Parian ware, differs so materially from that which is used in forming metal castings, each will be described in the notice of that branch of art to which they respectively belong (see PORCHAIN, Por-TERY, SCULTTURE), and the present article devoted to a brief account of the method adopted in founding iron custings of great size, and bells and statues in bell-metal and bronze. An account of type-founding will also be given under its proper heading (see Type-FOUNDING). After iron ore has been reasted, to drive off the arsenic, sulphur, and water that may exist in it, it is thrown in an enormous furnace (see Blast-Furnace, Iron Manufacture), with a quantity of coke and limestone, the latter of which acts as a flux to the and immestone, the latter of which acts as a liux to the ore, and promotes the melting of the iron. The following proportion is generally observed; namely, a ton and a half of coke and 8 cwt. of limestone, broken in very small pieces, to every ton of ore; but if pig iron be used, or iron that has been extracted from the ore, the addition of limestone is not necessary. When this mixture tion of limestone is not necessary. When this mixture is in the furnace, a strong current of air is directed against the glowing mass, and the metal sinks to the bottom of the furnace, leaving a quantity of scorie, technically called "slag," behind it, when the vent at the bottom has been opened, and the molten fluid allowed to escape. The model of the article to be cast is generally made in wood, and from these models moulds are constructed, being made of a peculiar kind of yellow sand, which has been well mixed and kneaded with a little water. If the article is to be made in a solid piece, there is not much difficulty in making the mould, which is generally fashioned in two pieces if the casting be cylindrical in shape, or in more than two if it be irregular in form; but when it is to be east hollow, a core is formed, to occupy the greater two if it be irregular in form; but when it is to be cast hollow, a core is formed, to occupy the greater part of the interior of the mould, leaving a certain thickness everywhere between the inner surface of the mould and the exterior of the core; the former of which gives the external form to the casting, and the latter the internal form. To make the core, a quantity of wax or clay is pressed into the mould, or parts of the mould if it be made in pieces, of the thickness required for the metal. The mould having been thus lined, is then built together, and the internal cavity tilled with sand, or a composition made for the purpose. The exterior mould is then that off, and the wax or clay, which represented the metal, is removed, leaving filled with sand, or a composition made for the purpose.

The exterior mould is then taken off, and the way or law to be the slaves or absolute property of those who clay, which represented the metal, is removed, leaving the gore around which the mould is subsequently built seems also to have prevailed among the Germania for the control of the slaves or absolute property of those who clay, which represented the mould is subsequently built seems also to have prevailed among the Germania for the carbon of children. Abandoned children were declared by law to be the slaves or absolute property of those who clay, which represented the mould is subsequently built seems also to have prevailed among the Germania for the carbon of children.

# Foundling Hospitals

up, being prevented from touching it by stops that are arranged to preserve the negessary space between the mould and the core. They are then thoroughly dried by being exposed to the action of heat, in a drying-stove. Great care is taken to insure perfect freedom from moisture, which would generate steam, and cause an explosion at the entrance of the metal. As soon as all parts of the mould are dry, they are built together and surrounded by sand, which is carefully banked up around and over the mould, to assist in resisting the weight of the metal when it enters; but if the casting be of considerable size, it is generally buried in a pit weight of the metal when it enters; out it the caseing be of considerable size, it is generally buried in a pit below the level of the furnace, which is filled with sand as soon as the mould has been built up in it, and in such cases the mould and core are strengthened by bars and hoops of iron, which have been introduced during the process of making them. Sometimes the moulds are packed with sand into frames of iron or casting-boxes. When all is ready, the furnace is opened, and the metal is allowed to run into the mould along channels made for the purpose, or if the mould be at some distance for the purpose, or if the mould be at some distance from the furnace, and the easting be of small size, it is carried from the furnace by men in large iron pots or crucibles. Sufficient time is then given to allow the casting to cool, after which the mould is broken off, and the iron, if necessary, is cleaned, and the external roughness removed by filing, &c. The above is an outline of the process used in making castings in iron, and it is pretty nearly the same for castings in all kinds of metal, with some slight difference, that is required either by the form of the article (see SERLL), or the peculiar metal of which it is made. In casting large bells for churches, eatherlas, and clock-towers, and groups of figures, or drais, and clock-towers, and groups of figures, or statues of great size, very large furnaces are required, as the whole of the metal used in the casting must be melted and run into the mould at one time. The pit in which the bell is cast is made near the furnace. The core consists of a mass of brickwork covered with a composition of loam and horse-dung, which is carefully fashioned to the shape of the interior of the bell. Another coating of composition is then added. after sprinkling the core with tan-dust to prevent one cost from adhering to the other, and this is carefully moulded to the form of the exterior of the bell, forming what is called the model. More tan-dust is then applied, and on the model a third coating is laid, called the shell, which eventually gives the form to the exterior of the bell. This shell is then carefully taken off and the model removed, after which the shell is built up round the core, and the pit illied with sand or loam. The bell-metal, formed of tin with sand or loam. The bell-metal, formed of tin and copper (see BELL-METAL), which has been melted in a furnace heated with wood, instead of coal or coke, is then allowed to run into the mould. After casting, the tone of the bell is duly regulated. (See BELL) The method used in casting bronze statues is similar to that adopted for castings in iron and bell-metal; but the composition of which the mould and core are made is different, consisting chiefly of a mixture of plaster of Paris and brick-dust. It is unnecessary to make large bronze castings in one piece as they oan be made in parts, which are afterwards soldered together. The composition of bronze is given under its proper heading. (See BRONZE.)—Ref. Wyat's Treuties on Metal-work. to make large bronze castings in one piece, as they

FOUNDLING HOSPITALS, found'-ling (Ang.-Sax.), are charitable institutions established for the care and upbringing of foundlings, or children that have been abandoned by their parents. The object of such institutions is to prevent the destruction of children, either tutions is to prevent the destruction of children, either by actual violence, or through exposure in the streets or highways; and their establishment dates from the middle ages. In ancient Greece and Rome the exposure of children was a frequent practice, as it is among the Chinese at the present day. Neither Plato nor Aristotle condemns it; they content themselves with laying down general rules for the preservation of the healther and stronger at the exposure of the more weakly. Thebes was the only state of ancient Greece that is known to have forbidden by law the exposure of children. Abandoned children were declared by

#### Fountain

nations before the introduction of Christianity. With the spread of Christianity, different feelings began to prevail on this subject; and the exposing of infants was forbidden by the emperors Valentinian and Gratian. At the same time, the stricter laws that came in force concerning marriage and against concubinage, rendered women more auxious than before to conceal their shame; so that, in fact, the danger to infants of being exposed or put to death was rather increased than diminished; and hence Gibbon has some research being exposed or put to death was rather increased than diminished; and hence Gibbon has some reason to speak of child-exposure as one of the most stubborn remnants of heathendom. So early as the 6th century a species of foundling hospital is said to have existed at Trèves; the then bishop of that place permitting children to be deposited in a marble basin which stood before the cathedral, and giving them in charge to the members of the church. The first well-authenticated instance, however, is that established at Milan in 787, but he archyeselvita Duthous. Subscannity found. by the archpresbyter Datheus. Subsequently, found by the archyresbyter Datheus. Subsequently, foundling hospitals were established at Montpellier in 1070,
at Eimbeck in 1200, at Florence in 1317, at Nürnberg
in 1331, at Paris in 1382, and at Venice in 1380. In
1198, Innocent III., when rebuilding the great hospital
of Santo Spirito at Rome, allotted a portion of it for
the reception of foundilings. This system prevails in
France, Spain, and Italy, and in general in all the
Roman Catholic countries in Europe; whereas in Protestant countries it is not looked upon with favour.
The principal chiection that has been reised presing The principal objection that has been raised against foundling hospitals is, that they tend to encourage founding nospitals is, that they tend to encourage illegitimacy; and the great argument in favour of them is, that they have the effect of preventing child-murder. The question is one of very great difficulty; but the prevailing opinion in this country has always been opposed to these institutions, as being, on the whole, more permisions than beneficial. Founding hospitals, too, are more necessary in those countries where there is no legal provision made for the poor, than where, as in our own, the mothers of illegitimate children, if unable to support them, may have recourse to the parish poor-house. The mortality in foundling hospitals has always been very great, though the evil has in some measure been mitigated in more recent times by means of improved management and the practice of means of improved management and the practice of giving out children to be nursed. The usual mode of depositing children in the hospital is by means of a turning-hox fixed in the wall, in which the child is laid, and, on a bell being ruug, it is taken in by one of the watchers. The proportion of illegitimate children in watchers. The proportion of illegitimate conuren me Paris is about one in every three births; and of the total number of illegitimate children, about 58 out of the foundling hospital. total number of illegitimate children, about 58 out of every 100 become inmates of the foundling hospital, where more than one-half of them die before they are a year old. The Foundling Hospital in London was established in 1739, by Captain Thomas Coram, a benevolent sailor, as "an hospital for exposed and deserted children." So great, however, was the influx of inmates, that the funds of the institution were inadequate to its support; and as the system did not meet with much favour in this country, the character of the hospital was, in 1760, changed from a founding to what it now is, an hospital for poor illegitimate children whose mothers are known. The committee requires to be satisfied of the previous good character canaren whose mothers are known. The committee requires to be satisfied of the previous good churacter and present necessity of the mother of every child proposed for admission. The qualification of a governor is a donation of £50. Among the principal benefactors to the hospital was the great Handel, who used to perform his oratorio of "The Messiah"

in the chapel. in the chapel.

Foundam, found-tim (Lat. fons, Fr. fontaine), a spring or source of water rising above the earth in a jet or jets, forced up by either natural or artificial means. Artificial fountains flow from vases, statues, or other picturesque pieces of sculpture. Among the ancients, fountains were generally esteemed Among the ancients, fountains were generally estaemed sacred, and sacrifices and libations were made in their honour. Horace, in his odes, gives a tribute of praise to one at Rome, distinguished by the appellation of Fons Blandssize. Many of the Greek cities were adorned with these beautiful and necessary objects of art, Corinth especially. In the ruins of Fompiliand Herculaneum, fountains were seen in nearly every situation; and, from the number of leaden pipes also found, it seems that every house was provided with 878

## Fourth

one. In modern Rome this practice of having fountains one. In modern Rome time presence of awaying obstants distributed through the city is kept up in the present day; and those of Trevi and the Pauline, at San Pietro in Montorio, are splendid piles of architecture, adorned with imposing pieces of sculpture. In Paris, the fountains of Versailles and St. Cloud used to be continued to the continued fountains of Versailles and St. Cloud used to be considered the finest in the world; but since the erection in England of the system of fountains at Sydenham Palace, they cannot be compared with the latter. Within the last year or so, much attention has been given to the necessity of public drinking-fountains in the streets and thoroughfares of London, and now many of them are supplied with some really artistic jets at each, through the liberality of some of the chief citizens. They are a necessity to a large city, and citizens. citizens. They are a necessity to a large city, and there is no doubt that ere long London will be as well or better supplied than Rome was in this respect.

or better supplied than Rome was in this respect.

FOURIERIEM, foot-re-er-izm, is the name given to a system of socialism promulgated by Charles Fourier (1772—1837), and which differs materially from the systems of communism strictly so called. It professes to be based upon natural laws, and to be founded on calculations which he maintained to be the counterpart. of Newton's physical system. This system, unlike communism, does not, in theory at least, withdraw any This system, unlike of the motives to exertion which exist at present, nor does it contemplate the abolition of private property. According to the Fourierists, there is scarcely any kind of useful labour which is naturally and necessarily disagreeable, unless it be either regarded as dishonourable, or is immoderate in degree, or destitute of the stimulus of sympathy and emulation. They therefore endeavour to strengthen and foster those motives for exertion that are naturally inherent in man. Society was to be formed into associations, or phalansteries, was to be formed into associations, or punantieries, each comprising 400 families, or 1,800 persons, numbers brought out by very careful calculations. The phalanstery was to include everything in structure and character which could gratify the highest taste and sense of enjoyment. The pursuits and functions of the members were to be infallibly adjusted through a distribution by which each person was to be set pre-cisely to that occupation in life to which his passions and propensities directed him. Life was thus to be a perpetual enjoyment, and labour, instead of being a task, was to be as much a source of enjoyment as the pursuits of the honter or the angler. The property of the association was to be held in 1,128 shares, and the whole products were to be divided into twelve parts; of which five were to go to labour, four to capital, and three to skill or talent. The capital of the community may be owned in unequal shares by different members, who would receive proportional dividends; and the claim of each person to the share of the produce appropriated to talent is estimated by the grade or rank which the individual occupies in the several groups of labourers to which he or she belongs. The remuneration, when received, would not of necessity be expended or enjoyed in common. The system, however, as a whole, is so complex, that Fourier himself never admitted that even the most ardent of himsel never admitted that even the most artent or his disciples understood it; and to the last he would sanction nothing as an announcement of his views that he had not himself written. An attempt was made to carry out Fourier's views practically in the neighbour-hood of the small town of Rambouillet, easily accessible from Paris. About £20,000 is said to have been expended in the attempt, which proved a failure. According to J. S. Mill, Fourierism is "the most skilfully combined, J. S. Mill, Fourierism is "the most skilfully combined, and with the greatest foresight of objections, of all the forms of socialism." It "does no violence to any of the general laws by which human action, even in the present imperfect state of moral and intellectual cultivation, is influenced; and it would be extremely rish to prouounce it incapable of success, or unfitted to realize a great part of the hopes founded on it by its partisans."—Ref. Encyclopædia Britannica, art. Communism; Principles of Potitical Economy, by J. S. Mill. Fourn, foarth (Ang.-Sax.), a distance comprising three diatonic intervals. There are three kinds of fourths; viz., the diminished fourth, composed of a whole tone and two semitones; the perfect fourth, consisting of two whole toges and a semitone; and the correme sharp, or superfluous fourth, consisting of three

extreme sharp, or superfluous fourth, consisting of three

whole tones.

## Fousil Oil

Fousic Oil, fou'-sii, in Chem. (C<sub>10</sub>H<sub>11</sub>OHO), a substance foundein brandies distilled from fermented potatoes, rye, barley, and the mare of grapes. Its chemical name is amylic alcohol, under which heading its properties are described.

FOVILLA, fo-vil-li (Lat. fo-vo), in Bot., the matter contained within the membranes of the pollen-grains. It is a semi-fluid granular protoplasm, in which are

this a semi-fluid granular protoplasm, in which are suspended very minute starch granules, and what appear to be oil globules. It is, without doubt, the essential part of the pollen-grain. (See POLLER.)

Fowl. (Sax. fuget).—In its general sense, this term is nearly synonymous with birds; but in a more restricted sense it means those domestic birds brought up in a farmyard for the table. Fowls originally came from Persia and India, and they are valuable to the breeder in many ways, yielding profit as they do in eggs, in broods, and in feathers. The different kinds of this useful domestic creature are the Cochin-Chins, the Hambro', the Spangled, the Spanish, the Bantam, the Malay, the Poland, the Brahmapootra, and the Dorking. Besides these there are several other scarce specimens; as the Japanese Bantam or Silky Fowl, the Enu or Silky Cochin, the Andalusian, the Rangoon, and the Ancona fowls, all of which are bred more for exhibition than for real utility. The Cochin-China is one of the largest of the different The Cochin-China is one of the largest of the different kinds, and the colours of its plumage are buff, lemon, kinds, and the colours of its plumage are buff, lemon, cinnamon, grouse, partridge, white, and black. They are capital layers, and in a short time a pair will stock a yard. The Hambro' fowl is one of the prettiest varieties, and has gold and silver plumage; they are also prodigious layers, but rarely have patience to bring up a brood. The Spanish fowl and the Dorking are the more commonly seen than the other varieties, and are certainly of more use to the breeder, being good sitters as well as layers. The Bantams are the createst favourities, being ramagliable amall birds and good sitters as well as layers. The Bantams are the greatest favourites, being remarkably small birds, and having delicate plumage. It would be impossible to give a description of all the different varieties here; but the reader is referred to "A Plain and Familiar Treatise on the principal Breeds of Fowls," by Mr. John Baily. The Guinea-fowl, or Pintado, is sometimes classed among the common order of fowls; they are very wild and restless in their nature, and, unlike the ordinary fowls, they give no notice to any one of their laying or and restless in their nature, and, unlike the ordinary fowls, they give no notice to any one of their laying or sitting; they have consequently to be closely watched. The Guinea-fowl is very delicate eating, and is in season about Lent. Their eggs are something like those of turkeys, but not so gross. As the Guinea-fowl rarely watches over her nest and rears a brood, its eggs are generally put under a common hen, which performs in a satisfactory manner the duties of foster-mother.

Fox, foks (Ang.-Sax.).—Until very recently, the foxes were placed, by the most eminent naturalists, together with the wolf and dog; but, according to the classification of the mammalia in the British Museum, which system is now generally adopted by zoologists,

classification of the mammalis in the British Museum, which system is now generally adopted by zoologists, it is separated from these animals, and placed in the genus Vulpes. In many particulars, it is true, the fox greatly resembles the rest of the genus Canis; but the shape of the pupil of the eye (which is elongated), the bullet head, the bushy tail, the long body, supported on short limbs,—all these characteristics fully establish the soundness and correctness of the restricts to the second. the soundness and correctness of the position to which the for is assigned in the collections of the great national repository of science. The common for (Vulpes vulgaris) is the only species found in this country. Of so well-known an animal, any minute description would be superfluous. Its colour is reddish-fawn, intermixed with black and white hairs; its tail, or "brush," is of the same colour, except at the tip, which is white. It measures about two feet and a half in longth, and twelve inches in height. Its coat is much heavier and thicker during the winter months. the soundness and correctness of the position to which much heavier and thicker during the winter months, much heavier and thicker during the winter months, when its fur is of greater value than in warmer weather. Linnaus restricts its geographical range to Europe, Asia, and Africa; Cuvier says it is found from Sweden to Egypt inclusively. In eighteen months, the fox attains maturity; and its life varies from twelve to fourteen years. As this, however, can only be said of those animals which have been captured young, or born in confinement, it is probable that, in a wild state, the fox lives to a much greater age. The fox emits a most unpleasant scent, which proceeds from certain glands

#### Fractions

situated at the root of the tail. This powerful odour is rendered more disagreeable from the remarkable tenacity with which it clings to any object which it has once touched. The common for lives on rabbits, hares, partridges; and when occasion offers it a chance of obtaining entrance into the farmyard, it often commits great have among the poultry. This food failing, it will resort to worms and insects for a means of subsistence; and, when dwelling near the sea-coast, sometimes makes a meal of the molluscs and orustaces it can manage to pick up on the shore. It burrows in the ground like the rabbit; and, indeed, often turns out that animal from its domicile to take up its own abode there. Besides the abeve species, there are several others:—the Persian for (V. flavesthere are several others:—the Persian fox (V. flaves-cens), the Arctic fox (V. lagopus), the American fox (V. calmus), the South-African fox, or Casma (V. Casma), the Senegal fox (V. dorsalis), the Kit fox (V. cenerco-aryentatus), the Kokree (V. bengalensis), the Salora (V. niloticus); and one or two others, which are doubtful members of this family.

FORGIOTH. (See DIGITALIS.)
FOX. GRAFES. (See VITIS.)
FOX. GRAFES. (See VITIS.)
FOX. GRAFES. (See VITIS.), a species of dog used in the sport of fox-hunting. An extraordinary amount of care and attention has been given to dinary amount of care and attention has been given to the proper breeding of this animal; and no pack can be justly considered perfect without each particular animal composing it being especially picked out as adhering to the rules laid down for the guidance of dog-fanciers. In the true foxhound, nearly all the individual good qualities which distinguish other varieties of dogs are combined; and, for fleetness, strength, fine scent, spirit, perseverance, and subordination, they have no equals. The foxhound is not a very large

FOXHOUND.

animal, his height averaging from twenty to twenty-two inches. The colour of the foxhound is generally pled; such as yellow, black, dun, fallow, and brown intermixed. In order to be perfect, an old authority on the classe observes, that the animal should be of the following properties. lowing proportions: his legs straight as arrows; his feet round, and of medium size; his shoulders black; his breast wide; his chest deep; his back broad; his head small; his neck thin; and his tail busby, thick, and well-carried. A celebrated forhound bitch, belonging to Colonel Thornton, named Merkin, has been known to run four miles in seven minutes and half a second,—a pace which nearly equals that of the fastest race-horse.

FOL-BUNTING. (See HUNTING.)
FRACTIONS, frük'-shuns (from Lat. frango, I break), a term applied in Arith. and Alg. to designate a part of any magnitude, integer (whole number), or unit. For example, "two and a fraction" means two units and that part of a unit which can be distinguished as one-half, two-fifths, and so on. In the fraction in arithmetic, or  $\frac{a}{1}$  in algebra, the figure 1 or a is the numerator, and 3 or b is the denominator; and they represent that, if a whole number is divided into three

#### Fracture

or b parts, only one or a parts are taken. In the addition of fractions, the fractions must be brought down to the same denominator, and their numerators (as expressed in the value of their new denominator) must then be added, when we have one whole fraction. Thus, if we want to add \( \frac{1}{2} \) we must find the least common multiple of 3 and 5, which is found to be 15; then, as 3 goes 5 times into 16, and 5 goes 3 times into the same number, we multiply the numerators of the different fractions by these respective quotients, and then add the two quantities together. Thus, \( \frac{1}{2} \) added to \( \frac{2}{3} \) will be 5 added to 6 fifteenths. The true definition of a fraction may be thus summed up:—It is the division of its numerator by its denominator; as seven-eighths are equivalent to the whole number 7 divided by 8,—whence a fraction is obtained. Decimal fractions simplify calculations greatly, as they are constructed on the principle of having one common denominator,—a multiple of ten; and thus fractions can be added, subtracted, and divided without repeating over and over the tedious process of bringing them down to a common denominator. (See ARITHMETIO and DECIMALS.)

and DECIMALS.)
Fractures, frak' ishur (Lat., from frange, I break), in Surg., is the term applied to broken bones. This is one of the commonest accidents to which one is liable, especially in very cold weather, when the bones are very brittle, and in certain conditions of the bones themselves. Fractures are divided into simple, compound, comminuted, and complicated. Simple fractures are divided to the simple fractures are divided to the simple compound. tures are those in which the fracture does not commutures are those in which the tracture does not communicate with the external air. These are by far the most common, and usually affect the shaft of long bones, this part being the most subject to injuries of this description. Compound fractures are those in which one or more bones are broken, and the fracture communicates with the external air by means of a wound in the soft parts. Comminuted fractures are those in which the bones are broken into several porthose in which the bones are broken into several por-tions; while complicated fractures are such as are complicated with some other injury; as a wound of the principal artery of the limb. Fractures are also dis-tinguished as transverse, oblique, or longitudinal, according to their direction. A transverse fracture is usually much more easily treated than an oblique; is usually made more easily treated than an obnde; for the parts, when placed in opposition, may be kept there without much difficulty; whereas, in the latter case, they are liable to be displaced by the movements of the muscles or parts; also, in the latter case, the of the muscles or parts; also, in the latter case, the contiguous soft parts are much more liable to be lacerated by broken edges of the bone than in the former. In treating the oblique fracture, the limb should, if possible, be placed in such a position as will relax the principal muscles connected with the bone; in the transverse fracture, the straight position is often the best. The general symptoms of a fracture are deformity of the limb, caused either by the overlapping of the bones, or effusion of blood, lymph, or serum into the cellular tissue, shortening of the limb, and crenitus, or a grating sound when the ends of the and crepitus, or a grating sound when the ends of the fractured bone are moved upon each other. The treatment of fractures consists in restoring the broken fragments, as nearly as possible, to their former positions, and securing them in that state. Where displacement has taken place, it is first of all necessary to soothe the mas taken place, it is first of all necessary to scotch the muscular irritation by means of gentle friction or warm fomentations, after which, by a gentle application of force, the bone is to be restored, as nearly as possible, to its proper position. When the limb has been retuneed, or set, it is to be placed in splitate, which are thin pieces of wood, or other material of the requisite firmness and length, shaped and hollowed out, so as off tevenly without making undue pressure upon any part. The skin is to be protected by folds of linen, or thin soft pads, a little wider than the splitats, which are also useful to prevent them from slipping. These of pressure, and they ought to be removed and readily supply and the production of the surface of the slip in order to detect and rectify any deviation that may be observable. The mode of healing, in simple fractures, differs little from the manner in which bone is originally formed. Immediately after the fracture has taken place, a quantity of blood is poured out into the surrounding cellular tissue by the vessels of the adjoining structures. Inflamma muscular irritation by means of gentle friction or warm by the vessels of the adjoining structures. Inflamma-

## Frame Bridge

tion sets in, and the periosteum becomes thickened; lymph is poured out, by which the ends of the bone are united, and in which bony matter is formed, until a complete union is effected. The period taken for the accomplishment of this varies according to the bone broken, the age, constitution, &c. of the patient. It is quicker in children than in adults, and in adults it is slowest in old age. Taking all ages, however, the time occupied is from two to eight or ten weeks. The treatment of compound fracture consists in placing the broken bones in opposition, and healing the external wound, so as to convert the compound into a simple fracture. This is best done, where it can be effected, by bringing the edges of the wound together with adhesive plaster, or with sutures if necessary. But the modes of treatment in this, and the other complicated cases of fracture, are so varied, and depend in so great a measure upon the circumstances of each particular case, that our limits do not admit of our entering upon them; which is the less to be regretted, as they can only be properly treated at the hands of a skilful surgeon.

Fractal at the hands of a skillul surgeon.

Fractalla, friga-ir-e-a (from Lat. fragrans, fragrant), in Bot., the Strawberry plant, a gen. of the nat. ord. Rosuceæ. Two species are natives of Britain; namely, F. vesca, the wood strawberry, and F. elatior, the hautboy strawberry. The latter is vory rarely met with in a wild state. From these and several foreign species, a great number of varieties have been developed. The fruit is remarkably-wholesome, and is regarded by most people as the choicest of our native fruits. In cultivating the strawberry, an open situation and a rich loamy soil are required. The planta, until the fruit is formed, demand copious supplies of water. The row-culture is most convenient, and frequent re-

The row-culture is most convenient, and frequent renewal insures vigorous plants and large fruit. FramBoRSIA, or YAWS, frünboe-'s-c-ü (Fr., from framboise, a raspberry), a disease of the skin, indigenous to the Antilles as well as Africa. It consists of imperfectly suppurating tumours, which gradually increase in size until they become as large as, and somewhat resemble, a raspberry. The period during which the disease is in progress varies from a few weeks to several months. When it has reached its height, it usually continues for some time without undergoing much change, and then passes away. It seldom proves dangerous, except from the mischievous interference of ill-directed art. The "master yaw," however, or one of the pustules that attains a much larger size to be treated with gentic escharotics. The framboasia is propagated solely by the contagion of the matter discharged from the cruption when applied to the broken skin of another person who has not previously had the disease; for it only affects the same person once.

Frame Bridge, frain-bridj(Ang.-Sax.), abridge built of beams of timber, and framed together, as it is technically called, in such a manner that any weight which may be placed on the structure exerts a crushing or pulling strain on the timbers in the direction of the grain of the wood, any disposition of the pieces that may cause a strain to be exerted on them transversely to the direction of the fibres of the material, being carefully avoided. In making frame bridges of considerable span, the timbers are often put together to present the form of an arch, in the same manner in which centrings are formed on which arches of brickwork or masonry are constructed (see Centerne); but, in the majority of bridges of this class, the weight is either thrown on a horizontal tie-beam by oblique timbers which support a pathway above, and are framed into the tie-beam abutting fitmly against it, and transmitting the weight in the direction of its length, as in the bridge of Schaffhausen, on the Rhine, in which no outward thrust is exerted against the piers on which the tie-beam which supports the structure is laid; or, on the contrary, in some, a great part of the weight is thrown on the abutments of the bridge by diagonal struts through which a considerable outward thrust is conveyed against them. Frame bridges are common in Switzerland, where a roof is frequently constructed over them, to shelter the main timbers of the bridge from the action of the weather. In erecting bridges of this description, care should be taken to prevent

878

their decay, from exposure to the weather, as far as possible, by guarding against the settlement of water in the joints of the timbers, and to promote a free circulation of the air about the ends of the beams that rest on or are imbedded in the masonry of the abutmente.

FRANING, frailming (Ang. Sar.), the name applied to the process of jointing and fitting together any kind of work composed of a number of different parts, whether in wood or metal. In carpentry, however this is generally called "joining," and the carpenter who is employed on such work is termed a "joiner."

who is employed on such work is termed a "joiner."

Franc, frink (Fr.), a French silver coin of the value of nearly tenpence sterling. The equivalent in our coinage is, that twenty-five francs go to make one sovereign. The franc, or frank, which was used in ancient times, was a gold piece nearly equal to a crown in value; and the old silver franc was in value equal to a third of the gold one.

Franchise, fran-tshiz (Fr., a privilege or freedom from any onerous duty), in Law, is defined to be "a royal privilege or branch of the king's prerogative subsisting in the hands of a subject." It thus must necessarily arise from a king's grant, or it may be held by prescription, which supposes a grant. The different by prescription, which supposes a grant. The different ginds of franchise are almost infinite; but among them may be mentioned the privileges of bodies corporate, the right to hold courts leet, fairs, markets, ferries, forests, chases, parks, swarrens, and fisheries. They may be lost or forfeited by the parties who enjoy them; and the remedy for the disturbance or interference with a franchise is an action on the case. The right of voting at an election for a member of parliament is also termed a franchise.

FEANCISCANS (GREY), or MINOR FEIARS, frün-siekäns, in Eccl. Hist., constituted one of the four orders käns, in Eccl. Hist., constituted one of the four orders of mendicant friars, and were termed Franciscans, after their founder, St. Francis; Grey, from their grey clothing; and Minor, or Minorites, in token of their humility. The order was established by St. Francis at Assisi, in Naples, in 1208. It was distinguished by vows of absolute poverty and a renunciation of all the pleasures of the world, the members being strictly prohibited from having any property whatever. The rule of the order, sanctioned by the pope in 1210 and 1223, destined them to beg and preach. The popes granted them many extensive privileges, which excited the envy and opposition of the secular clergy, upon whose rights they often made great encroachments; whose rights they often made great encroschments; and they refused to acknowledge any authority whatever but that of the pope. They spread with great rapidity, and at length comprised many thousand monasteries, all established by alms and contributions. monsteries, all established by alms and contributions. The rule of poverty, so strictly enjoined by their founder, came in time to be somewhat relaxed, and the monasteries were permitted to hold property. Learning, too, which was at first despised, came to be cultivated within their monasteries, and many of their members became distinguished as scholars; as Bonaventura, Duns Scotus, Roger Bacon, and others. Several of them have also rison to the highest offices of the Church: poses Nigholas IV. Alexander V. of the Church; popes Nicholas IV., Alexander V., Sixtus IV. and V., and Clement XIV. being of this order. Many of their early austerities were greatly mitigated; and this and other differences led to nu-merous divisions and subdivisions among them. Among the minor orders of the Franciscans thus formed, are the Casarinians, Celestines, Spirituals, Soccolanti (or sandal-wearers), Observantes, Capuchins, Cordeliers, Alcantarines, &c. In the middle of the last century, there were above 7,000 houses of this order, having in them above 115,000 monks, besides about 900 convents, having 28,000 nuns. The Franciscans are not now very popular in Europe, and have been suppressed in more than one kingdom; but they are still one of the most numerous bodies of the Roman Catholic church, and have missions established in almost every part of the world. They are very numerous in the United States of America. The Franciscans are said to have come over into England in 1224, and to have had their first house at Canterbury and their second in London. They subsequently became very numerous in this country.

FRANCOACEE, fran-ko-ai'-g-e, in Bot., the Francoa fam., a nat. ord. of Discolyledones, sub-class Calyciflore,

consisting of stemless herbs with exstipulate leaves and regular flowers, the symmetry of which is quaternary. There are but two genera,—Frances and Tetilla, and regular howers, the symmetry of which is quater-nary. There are but two genera.—Francha and Tetilla, and five species, all natives of Chili. The Francas are reputed to be cooling and sedative; Tetilla is astringent, and is employed as a remedy for dysentery. Frank, frank, is a name given by the Greeks, Turks, Arabs, and other eastern nations, to a Christian. It probably originated at the time of the Crusades, in

which the French particularly distinguished themselves. This was also the name of a powerful German tribe that about the 3rd century of the Christian era were found inhabiting the lower Rhine, and which afterwards overthrew the Roman empire in the north-east of Gaul; overturew the nomine mighten the norm-east of Gauli, whence, in German, that country is termed Frankreich, i.e. the kingdom of the Franks. About the middle of the 4th century they became divided into two groups, the Salic and the Ripunric Franks, the former inhabiting the Low Countries, the latter extending themselves up the Rhine as far as the Main. Each group had its own laws, which, however, did not differ much from each other, and are known as the Lex Salica and the Lex Ripuariorum. The Franks form at the present day Les Rippariorum. The Franks form at the present day the ground (grundlage) of the people of western Ger-many as far as the Neckar, Main, Murg, and the Lower Alsace, as well as the chief Germanic element of the people of northern France. - Ref. Brockhaus' Convereations Lexikon.

FRANK, or FRANKING LETTERS, was the privilege en-FRAME, OF FLAMEING LETTERS, was the privilege enjoyed by the members of both houses of parliament, and many official persons, of sending or receiving a certain number of letters, free of postage, which was abolished on the introduction of the penny postage system in 1840. Before that time each member of either house of parliament was allowed to send daily ten letters, not exceeding an ounce in weight each, to our place in the United Windows and to receive affects any place in the United Kingdom, and to receive tifteen

any place in the United Anguom, and o receive inten-free of charge; a privilege which was greatly abused. Frankalmoigne, freach!-moin (Ang.-Nor.), (Lat. libera eleemosyna, free alms), in Law, is that kind of tenure whereby a religious corporation, aggregate or sole, holdeth lands of the donor to them and their suc-cessors for ever. This is the tenure by which almost all the ancient monasteries and religious houses held their lands. The service which they were bound to render for them was not certainly defined; but only in general to pray for the soul of the donor and his heirs, dead or alive; and therefore they did not fealty (which is incident to all other services), because this divine service was of a higher and more exalted nature. This form of tenure still continues, though the nature of the service was changed at the time of the Reformation, and made conformable to the purer doctrines of the Church of England. If those who hold their tenements in frankalmoigne fail or refuse to perform the enjoined service, the law gives no remedy by distress or otherwise to the lord of whom the lands are holden; he can only complain to the ordinary or visitor, praying him to correct and punish the omission, and provide that such negligence be no more done. The statute of 12 auch negligence be no more done. The statute of 12 Car. II. c. 24, which abolished the old tenures, specially reserved tenure in frankalmoigne.

reserved tenure in frankalmoigne. FRANKENIAGER, franke-n-e-ui-se-e (after John Frankenius, professor of botany at Upsai), in Bot., the Frankeniu fam., a nat. ord. of Dicotyledones, subclass Thalamifora, consisting of herbs and undershrubs much branched, with opposite exstipulate leaves and sessile flowers; calyx tubular, furrowed, persistent; petals unguiculate, 4 or 5, hypogynous; stamens hypogynous, distinct; ovary superior, 1-celled, with parietal placentas; fruit capsular, 1-celled, inclosed in the calyx and dehiscing in a septicidal manclosed in the calyx and dehiscing in a septicidal manner; seeds aumerous; embryo straight, erect, in the middle of albumen. The plants of the order chiefly occur in the south of Europe and north of Africa, but are found in other parts. They are mucilaginous and slightly aromatic. The leaves of a species of Beatsonia are used at St. Helens as a substitute for tea.

Frankingurss, frink-in'-sens (Ang.-Nor.), a name given to a species of gum-resin derived from the Boswellia serrota, and imported from the Levant. By melting it in water, and straining it through coarse cloths, it is cleaned from a good deal of the oil which is one of its component parts,—the oil which is extracted being termed Burgundy pitch, or white resin. If

frankincense is sprinkled on coals, it emits a peculiar

frankincense is aprinkled on coals, it emits a peculiar aromatic odour; whence its name.

Frankelin, frink'-lin (Ang.-Nor.), was the ancient name for a freeholder of considerable property in England. In Chaucer's time, a franklin was a man of substance, enjoying abundance of good cheer, a chief man at the sessions, had been a sheriff, and frequently hight of the shire. The franklin of that day was evidently a person of importance; but, in Skakespeare's time, he stands much lower, being only a yeoman, a man above a wassal or villain. There appears, however, to be no foundation for Dr. Johnson's definition of a franklin as "a gentleman servant, steward, or bailiff."

Frank-marriagium), in Law, was a species of estate tail now gone out of use, and which is defined to be "Where tenements are given by one man to another, together with a wife, who is the daughter or course of

"Where tenements are given by one man to another, together with a wife, who is the daughter or cousin of the donor, to hold in frank-marriage." This implied that the donees should have the tenements to them and the heirs of their two bodies begotten; that is,

they were tenants in special tail.

FRANK-PLEDGE, frank-pledj (Ang.-Nor.), (Lat. franci plegium), in the early customs of England, denotes a pledge, or surety, for the behaviour of a freeman, called also friburgh. Before the Norman conquest, a called also fribirith. Before the Norman conquest, a law prevailed in this country, of the members of each district or circuit being made responsible for the good conduct of each other. Every free-born man, at the age of fourteen (religious persons, clerks, knights, and their eldest sons excepted), was bound to find surety for his truth towards the king and his subjects, or else to be kept in prison. Hence it became customary for a certain number of neighbours to become bound for one another, to see each man of their pledge forthcoming at all times, or to answer for the offence of any new absention binned. This was called frame-pledge one absenting himself. This was called frank-pledge, and the circuit thereof was called decenna, because it usually consisted of ten households. The sheriffs at every county court did, from time to time, take the onths of young persons as they grew up to fourteen years of age, and to see that they were settled in one decennary or another; whereby this branch of the sheriff's authority was called visus franci plegii, or view of frank-pledge. Whenever any one offended, it was forthwith inquired in what pledge he was, and then those of that pledge either produced the offender within thirty-one days, or satisfied for his offence.

TRABERA, frie-ze'-rū (named after John Fraser, a collector of North-American plants), in Bot., a gen. of herbs belonging to the nat. ord. Gentianaceæ. The root of the species F. carolineasis, or Walteri, has properties similar to gentian-root, but is less powerful. It is known as American columba, and is officinal in the Pharmacoponia of the United States.

FRATERNITY, fratter-ne-te (Lat. frater, a brother), signifies literally a body of men united together in one brotherhood, and in Roman Catholic countries denotes societies originated for purposes of devotion. These are of several sorts, the more remarkable of them being.—1. of the Rosary, founded by St. Dominic, and divided into two branches, called the Common rosary and the Perpetual rosary, the latter being under rosary and the Perpetual rosary, the latter being under very strict engagements, and enjoined to repeat the rosary continually; 2. of the Scapulary, whom, according to the Sabbatine bull of John XXII., the Virgin has promised to deliver out of hell the first Sunday after their death; 3. of St. Francis's girdle, who are clothed with a sack of groy colour, which they tie with a cord, and in processions walk barefooted, carrying in their hands a wooden cross; 4. of St. Augustine's leathern girdle, which comprehends a great number of devotees. Italy, Spain, and Portugal are the countries where the greatest number of these fraternities are to be seen, some of which assume the name of arch-fraternities. Pope Clement VII. instituted the arch-fraternity of Charity, which distributes bread every Sunday among the poor; and the fraterbread every Sunday among the poor; and the frater-nity of Death buries such dead as are abandoned by their relations, and causes masses to be celebrated for

FRAUD, fraud (Lat. fraus), in Law, includes all deceitful practices, in defrauding, or endeavouring to defraud, another of his known right, by means of some artful device, contrary to the plain rule of common

honesty. It is condemned by the common law, and punishable according to the beinousness of the offence. All frauds and deceits for which there is no remedy by the ordinary course of law are properly cognizable in equity, and, indeed, constituted one of the chief branches of cases to which the jurisdiction of chancery was originally confined. There are few cases of fraud that are not cognizable by equity, though in most cases the courts of law have a concurrent jurisdiction. Where a fraud can be clearly established, courts of law exercise a concurrent jurisdiction with courts of law exercise a concurrent jumps of the depth of the concept of the detection. A fraudulent conveyance of lands or goods to deceive creditors is, as to creditors, void in law; and a fraudulent conveyance to deceive purchasers is also to such purchasers void. Where a person is party to a fraud, all that follows by reason of that fraud to a fraud, all that follows by reason of that fraud shall be said to be done by him. A party prejudiced by a fraud may file a bill in equity for a discovery of all its circumstances. Mere inadequacy of price alone is not a ground for a court of equity to annul an agreement; but if there be such inadequacy as to show that the person did not understand the bargain he made, or was so oppressed that he was glad to make it, knowing its inadequacy, it will show a command over him which may amount to a fraud. If a person be fraudulently prevented from doing an act, equity over him which may amount to a trade. It a person be fraudulently prevented from doing an act, equity will consider the act as done; and equity also relieves against bargains made under misconception of rights. In treaties, concealment of a material fact by one of the parties, in order to keep the other in ignorance, whereby to profit, is a gross fraud, and the contract will be set aside in equity. Suppressio veri (suppression of truth), suggestio falsi (suggestion of falsehood), in solemn conveyances, releases, or agreements, will afford a sufficient ground for setting them aside. Constructive fraud is applied to such acts or contracts as, though not originating in any actual evil design or contrivance to perpetuate a positive fraud or injury upon other persons, yet, by their tendency to deceive or mislead other persons, or to violate public or private confidence, or to impair or injure the public interests, are deemed equally reprehensible with positive fraud, and are prohibited by law, as within the same reason and mischief as acts and contracts done malo animo. Gross criminal frauds are punishable by way of indictment or information; such as playing with false dice, causing an ill-terate person to execute a deed to his causing an illiterate person to execute a deed to his prejudice, &c. For these and such-like offences, the party may be punished with fine and imprisonment. Fraude are not indictable at common law unless they be such as affect the public; as vending unwholesome provisions, or using false weights or measures; or by way of conspiracy; or unless they affect the crown or the administration of justice.

the administration of justice.

FRAINIOFER'S LINES. (See SPECTRUM.)

I break, in allusion to its brittleness), in Bot, the Ash, a gen. of the nat. ord. Oleaceæ. consisting of about fifty species, mostly natives of Europe and North America. The leaves are deciduous, and are pinnste, with a terminal leaflet. The flowers are very imperfect, the calyx being obsolete, and the corolla either wanting or —4-partite. The fruit is a samara (which see). F. excelsior, the common ash, a native of Britain, is a beautiful and umbrageous tree, rising to the height of 100 to 160 feet. The wood is white, tough, hard, and light, much valued by wheelwrights, coachmakers, and turners. It is peculiarly adapted for agricultural implements, handles for tools, and ladders. Some interesting varieties have been developed by cultivation: the weeping ash, with branches drooping to the the weeping ash, with branches drooping to the ground; the curled leaved ash, with dark-green wrinkled or curled leaves; and the entire-leaved ash, with many or all the leaves simple. F. americana, the American or white ash, is a very fine tree, common in Canada and New Brunswick, with wood similar to that of F. excelsior. The sweet concrete exudation known as manna is procured by making incisions in the stems

of certain species of Frazinus, chiefly F. Ornus and rotundifolia, natives of Calabris, Apulia, and Sicily. Manna is a mild agreeable laxative. It owes its properties to a peculiar resin called mannite. The insect which produces the white wax of China feeds upon the species F. chinansie.

which produces was a species of chisensis.

FRECKLES, frek'-Is (Lat. lentigines), are small yellow or brownish spots which appear on the face, especially of fair persons much exposed to the weather. Various applications have been proposed for their removal; and perhaps the best is a limiment composed of limewater and oil, with the addition of a little ammonia.

FREE BENCH, Free bench (Sax. frig. fresh, benc, bench; Lat. sedes libera, or francus bancus), in Law, is that share in copyhold lands which a widow hath on the death of her husband, and which is regulated, as to its quantity, quality, and duration, according to the custom of the particular manor. It is generally a third for life, as at common law; but it is sometimes a fourth part only, and sometimes but a portion of the rent. Frequently the customary right is during widowhood only, and in some manors, if this widow be found guilty of incontinency, she loses her free bench, unless she comes into court riding backwards upon a black ram, and repeating certain ridiculous words. Free bench differs from dower at the common law, in that the former does not attach, even in right, till the actual decease of the husband; whereas the right to dower attaches immediately on marriage.—Ref. Wharton's Low Lexicon.

FREEBOOTER, free'-boot-er (Ger. freiheuter, Fr. flibustier), is a name given to a class of adventurers who have existed at different times and in different countries, but more particularly in the New Continent, and who were usually remarkable for their daring and intrepidity. (See Buccaneers, Filieusters.)

Fire Church, free takurish, is the name assumed by the largest and most influential religious body in

Scotland who differ from the principles of the established church, and who separated themselves from it at the disruption of 1843. They refuse to be called dissenters, because they contend that their principles are those of the Church of Scotland, and that it is the established church, and not they, that have departed from the principles of the Church, as set forth in the Confession of Faith and the other staudards. They are also known as Non-intrusionists, from the great principle against which they contended being the intrusion, or establishing, of a minister in a church by the patron, contrary to the wish of the people. It is a characteristic feature of Presbyterianism, especially in Scotland, that the people have a considerable voice in the affairs of the Church, and that a certain amount in the affairs of the Church, and that a certain amount of deference is to be paid to the popular mind. They have, also, always been opposed to any interference of the civil powers in ecclesiastical matters. By an act of the Scottish parliament in 1567, "anent the admission of them who shall be presented to benefices," it is ordained "that the examination and admission of ministers shall be only in the power of the kirk;" and while reserving the presentation of laic patronages to the ancient patrons, it provides that if the presentee of a patron should be refused to be admitted, it shall be lawful for the patron "to appeal to the General Assembly of the whole realm, by whom the cause being decided, shall take end as they decern and declare." After the union of the two crowns, an act was passed in 1711, as shall take end as they decern and declare." After the union of the two crowns, an act was passed in 1711, as Bishop Burnet says, "merely to spite the Presbyterians, who, from the beginning, had set it up as a principle that parishes had, from warrants in Scripture, a right to choose their ministers." This act declared, that, from and after the 1st day of May, 1712, it shall and may be lawful for her Majesty, her hairs and successors and every other person or her heirs and successors, and every other person or persons who have any right to patronage or patronages, of any church or churches whatever, in that part of Great Britain called Scotland, to present a qualified minister or ministers to any church or churches whereof they are putrons." Attempts were made by the Assembly, from time to time, to obtain a repeal of this measure, but without success; but it is said to have been so unpopular, that, for some years, the patrons were afraid to use the power invested in them, and for fifty years after the passing of that act the Church frequently enforced the non-intrusion prin-

ciple, pronouncing judgments is her courts which show that she either refused to recognize the act, or else regarded it as not interfering with her prerogative. By degrees, however, the right of patrons became more absolute, and the courts of law decided that the ecclesiastical powers might settle the minister in a parish, but that they could not secure him the stipend. About the middle of the last century, also, a large party sprang up in the Church, known as the Moderates, where adouted the views of the nature segment the records. d the views of the patrons against the people; and after many a fight, in which sometimes the assistance of the military had to be called in to settle a minister in his church, the right of the patrons had become absolute. The question of patronage had slumbered for about half a century, when it was again brought into life in 1833, by Dr. Chalmers, who brought his veto measure before the General Assembly, to the effect that the dissent of a majority of the male heads of families resident within the parish, being members of the congregation, and in communion with the church for a period of at least two years, ought to set aside the patron's nominee. The measure was at first rejected; but it was carried the and after many a fight, in which sometimes the as ought to set aside the patron's nominee. The measure was at first rejected; but it was carried the following year, and became law. Nothing occurred to disturb this law till 1837, when the earl of Kinnoul, having as patron presented Mr. Young to the vacant living of Auchterarder, the congregation were so dissatisfied with him, that a protest against his settlement was signed by 287 out of 330 persons on the communion roll. Against the decision of the church courts, Mr. Young appealed to the Court of Session. The highest legal talent was employed on both sides, and after lengthened pleadings the indees decided by The highest legal talent was employed on both sides, and after lengthened pleadings, the judges decided, by a majority of eight to five, in favour of Young. The discussion turned mainly upon the question whether it was competent for the General Assembly to pass such an enactment as the Veto act. The civil court having decided that the Veto act was illegal, the struggle now took a new form,—resistance to civil encroachment on the spiritual jurisdiction of the Church, as well as the maintenance of popular rights. Resolutions in support of the independence of the Church were passed in the Assembly to 1838 and it was agreed to apueal from the Assembly of 1838, and it was agreed to appeal from the Assembly of 1005, and it was agreed to appear it of decision of the Court of Session to the House of Lords, which was accordingly done. The House of Lords confirmed the decision of the inferior court, holding connimed the decision of the interior court, nothing that the Church, in the matter of the fitness of a presentee, "must strictly limit herself to judge of his personal qualifications; that is, his life, literature, and manners." The decision gave great offence to the nonintrusionists. In another case, that of Lethendy, the presbytery ordained a clergyman to the parish church, in the face of an interdict from the Court of Session, and the members of the presbytery were brought before the bar of the court, and subjected to a severe censure. In the Marnoch case, on the other hand, seven clergy-men, forming a majority of the presbytery, complied with the order of the Court of Session, and were sus-pended from their ministerial office by the commission of the General Assombly. The seven presbyters appealed to the civil court, and their opponents were interdicted from preaching in the churches, churchyards, or school-rooms, of the seven deposed presbyters. In 1849, Lord Aberdeen introduced a bill into parliament, with theyiew of composing these differences parliament, with theview of composing these differences and putting the points in dispute on a proper basis; but it was regarded as unsatisfactory by the General Assembly, and was consequently akandoned. Another attempt to heal the breach by act of parliament was made in 1841 by the duke of Argyle, who brought a bill into parliament which was substantially a repetition of the Assembly's Veto act; but parliament having been suddenly dissolved, the measure fell to the ground, In 1842 the General Assembly drew up a claim of right. or "a claim, declaration, and protest anent the en-croachments of the Court of Session," asserting the croachments of the Court of Scssion." asserting the sole headship of Christ over the Church; citing the various statutes by which the independence of the Church and its ovil rights and privileges had been secured; and claiming, in the name of the Church and on behalf of the nation and people of Scotland, as of right, freely to posses her liberties, and to be protected against the encroachments of the Court of Session. This claim was laid before the Queen, and in reply, Sig James Graham addressed a letter to the General

## Freemasonry

sembly, in which the chain of right was pronounced to sembly, in which the chain of right was pronounced to be unreasonable, and the intimation conveyed that the government could not advise her Majesty to acquiesce in these demands.—The disruption took place on the 18th of May, 1843, "the greatest event," says Lord Cookburn, "that has occurred in Scotland since the rebellion in 1745, if not since the union." The General Assembly met on that day, and, after prayer, the mo-derator, Dr. Welsh, read a lengthened and solemn protest against the repeated encroachments of the civil protest against the repeated enconcennents of the divi-power upon the Church, and concluded with a declara-tion that since they could no longer with a clear con-science remain within the Church, it was lawful for them, and others who might concur with them, to sepa-rate themselves from the establishment, and to adopt such measures as might seem proper for the advance suon measures as might seem proper for the avance-ment of God's glory and the proper administration of the affairs of His Church. Having read the protest, he turned towards the commissioner, and bowing respect-fully, slowly retired, followed by Drs. Chalmers, Gor-don, Macfarlane, and all who adhered to them.—The scene was deeply solemn and affecting. Whatever difference of opinion might exist as to the matters in dispute, no one could help admiring the nobleness of the men who had sacrificed all their worldly interests for what they believed to be right and true. The im-mense crowd of spectators looked on with feelings of the intensest interest, many of them being melted to tears.
"There was no hurry, no rush, no confusion—bench after bench was vacant—man after man the protesters atter bench was vacant—man atter man the protesters withdrew in silence, till one entire side of the Assembly, lately so crowded, was left with scarcely an occupant." It had been confidently represented by their opponents, and it is said that the government was influenced by the representation, that except a few of the leaders, the representation, that except a new of the leaders, who might be prevented by shame or wounded pride from retracing their steps, few, or perhaps none, would actually secede. That any large secession would take place, they never for a moment calculated upon. More than 400 ministers, however, left the church of their fathers, and, in that act, abandoned for ever their homes and their means of support, and now cast themselves without reserve upon the sympathies of the people and the good providence of God. They passed through streets crowded by an onthusiastic throng, who wel-comed them with shouts of admiration and gratitude, and proceeded to Canon Mills, where a large hall, capable of accommodating 3,000 persons, had been previously prepared for them. Dr. Chalmers was chosen moderator of the first General Assembly of the Free Church, which continued its sittings to the end of May. On the 23rd of May, an "Act of Separation and Deed of Demission" was adopted, and signed not and Deed of Demission" was adopted, and signed not only by those olergymen who were members of assembly, but by all the others who participated in their views, the number being 474; and, in almost every case, the great majority of their congregations went along with them. The Disruption ministers met with much sympathy throughout the country, and before the new General Assembly rose, Dr. Chalmers anounced that an aggregate sum of £232,347 had been contributed for the support of the Free Church; and during the first veer of its existence its income during the first year of its existence, its income amounted to £366,720. But while it was thus meeting with so much popular sympathy, the moderate purty and their adherents were doing everything in their power against them. The majority of the nobility and and their adherents were doing everything in their power against them. The majority of the nobility and great landed proprietors went with the established church, and some of them were guilty of very crucl and oppressive acts towards the non-intrusionists. Some of them, for a long time, refused to grant any sites on their lands for churches or other buildings, though nearly all have now conceded this favour. Yndeed, people at a distance could scarcely conceive how high party feeling ran, and what bitterness existed between the two parties; and scarcely less remarkable is the degree to which it has passed away in so short a time. Indeed, there are not wanting persons on both sides who entertain lopes that a union may yet be effected; for the Free Church has always kept tenaciously to the principle of an established church, and this has been the only thing that has prevented a union between them and other bodies who have seceeded from the established church, and who are opposed to the principle of state endowments. There can be little

hope of a union, however, unless the State very considerably modifies the laws with regard to patronage. The progress of the Free Church since 1843 has been very remarkable. A sum of upwards of £3,000,000 sterling has been contributed to its various schemes down to the present time. It has upwards of 800 ministerial charges, present time. It has upwarted to contaminate in the greatest besides numerous preaching-stations; it supports missionaries in all parts of the world; has established schools in almost every parish; built churches, manses, schoolhouses, &c.; and has colleges or theological hell for the education of its ministers in Edinburgh, Classical Advances. gow, and Aberdeen. A new source of annoyance has recently arisen, and brought them into collision with the civil power. In 1858, the Free Church minister of Cardress was charged with immorality, and was suspended by the General Assembly. From this decision he appealed to the Court of Session, for which proceeding the General Assembly at once deposed him. After much discussion, the case was at length thrown out on technical grounds, though the fact of the Court of Session entertaining the case was a recognition of the principle sgainst which the Church connition of the principle sgainst which the tended; namely, the right of the civil courts to review their ecclesiastical decisions. The General Assembly opposed the civil jurisdiction on the ground that the minister was subjected to a declaration that he would conform to the regulations of the General Assembly, conform to the regulations of the General Assembly, which preclude all appeal to the civil powers. The court, however, held that this could only apply to the ecclesiastical duties, and not to his civil rights, which had been affected by the decision of the General Assembly. The pursuer, Macmillan, again in 1863 commenced his action sgainst the Assembly, in a revised form, and the issue of it was undecisive. The tenets and government of the Free Church are identical, except in the points already indicated, with those of the Church of Sootland. (See Scotland, Church of Diplets of the Church of Sootland; Marsder's History of Christian Churches and Sects.

FREE CITIES, free sittless, is the name given to

FEEE CITIES, free sit'-ecz, is the name given to cortain German cities which form of themselves independent states. They are Hamburg, Bremen, Lubec, and Frankfort-on-the-Maine, and are all members of the Germanic Confederation.

FREEDOM AND NECESSITY. (See FREE WILL.)

FREEDOM AND NECUSSITY. (See PRES, LIBERTY OF.)
FREEDOM OF THE PRESS. (See PRESS, LIBERTY OF.)
FREEHOLD, free'-hold (Ang.-Sax.), (Lat. liberum tenemently, frank tenement), in Law, is an estate in lands or other real property, held either in fee, in tail, or for life, independently of the will of the foudal lord, and is used in opposition to copyhold lands, held during the will of the superior, or for a term of years. By the feudal law, none but a freeholder was regarded as having possession of the land, and no person who had an estate for less than a lifetime, either his own or some other person's, as his wife's, was regarded as a freeholder. Freehold also extends to offices which a man holds either in fee or during life.

TREEMAN, or FREEDMAN, free'-man, freed'-man, is a term used in contradistinction to a slave, and denotes one that is born or made free, and who enjoys certain privileges which are denied to the other. The title is also given to one admitted to the freedom of a corporate

town, or of any other corporate body.

FREEMAN'S ROLL, free'-manz role.—By the Municipal
Corporations Act, 6 & 7 Vict. c. 78, it is enacted that
the town clerk of every borough shall make out a list (to be called the freeman's roll) of all persons admitted burgesses or freemen, who were entitled to a share or benefit of the lands and public stock of the borough before the passing of such act, for the pur-pose of reserving such rights, and as distinguishing them from the burgesses newly created by the act, and entitled to the rights which it newly confers; these last to be entered on another roll, called the burgess roll.

FREEMASONRY, free-mai'-son-re (Fr. maçon; mason), is a term applied to a secret and wide-spread association, who term themselves Free and Accepted Masons. tion, who term themselves free and Accepted Masons. Societies of Freemasons exist in all parts of the civilized world, and their members are of every religion and condition of life. Every candidate, before his initiation, comes under a solemn engagement never to divulge the mysteries of the order, nor to communicate to the uninitiated the secrets with which he may be intrusted.

and the proceedings and plans in which the fraternity may be engaged. After the candidate has undergone the necessary ceremonies, and received the usual in-structions, appropriate words and significant signs are imparted to him, that he may be enabled to distinguish his brethren of the order from the uninitiated, and to convince others that he is entitled to the privileges of a brother, should he be visited by distress or by want in a distant land. After a due interval of probation, if the newly-admitted member be found qualified for a higher degree, he is promoted, till he has received that hasonic knowledge which enables him to hold the highest offices of trust to which the fraternity can raise agness omces of trust to which the traterinty can raise its members. At regular and appointed seasons, convivial meetings of the fraternity are held in lodges, constructed for the purpose; and all distinctions of rank are laid aside, all differences in religious and political matters forgotten, and peace and harmony generally prevail. Every one strives to give happiness to his brother, and men seem to recollect for once that they are arount from the content that they are arount from the content that they are around from the content that they are a content to the content that they are a content to the content that they are a content to the content once that they are sprung from one common origin, and are possessed of the same nature. According to its own peculiar language, Masonry is founded on "the practice of social and moral virtue." Its character is practice of social and moral virtue." Its character is charity in the most extended sense, and "brotherly love, relief, and truth" are inculcated in it. Like every other society of any duration, it has been subject to the influences of human frailties; and while it has been the means of effecting mach good, it has doubtless at times also been productive of much evil. Recently much has been written both for and against Freemasonry, its ritual, benefits, and tendency; while books have even appeared professing to reveal all the secrets of the order; but most Masons maintain that the true secret of Masonry has never yet been divulged, and there are many even Masonic writers, defenders of the society, who yet call its secret signs and rites accidental and unimportant. No one, we believe, even among intelligent Masons themselves, credits the great antiquity which some of their suthors claim for it. According to some, it is as old as the creation, while others only carry it back to the building of the tower of Babel, and some are content with tracing it no farther back than the building of Solomon's temple. It is asserted that the institution has been continued down, in uninterrupted succession, has been continued down, in uninterrupped succession, from that very remote period to the present day, through all the changes of governments, religion, civilization, and knowledge. It is indeed not improbable, that, after building rose to be a separate art, and to demand a certain amount of skill and training, those who were members of the order should seek to impart a mystery to their profession, and adopt certheir knowledge to others. The later Eleusinian, or other mysteries, to which others trace its origin, may have also imparted to it something of their character; but there is nothing in history, or in the character of Masonry, to warrant us in giving it so high an origin. Missorry, to warrant us in giving it so high an origin. Without, therefore, attempting to unravel its early history, we may state, generally, that the desire for magnificent churches and monasteries by the Roman Catholic priests led to great encouragement being given to the artificers of such works. The pontifis of Rome, and the other potentates of Europe, conferred the factoristic forms. on the fratornity of masons the most important privi-leges, and allowed them to be governed by laws, cus-toms, and ceremonies peculiar to themselves. Such encouragement must have been productive of the most benevolent fund for sged Masons, established in 1842; beneficial results to the fraternity. The association was composed of men of all nations; of Italian, Grewl, french, German, and Klemish artists, who were denominated Freensons, and who, ranging from one country to another, creeted those elegant churches and cathedrals which still excite admiration. Their government was remarkably regular, and the members government was remarkably regular, and the members government was remarkably regular, and the members of Roslin, and founder of the chapel of Roslin, and swidows fund, established in 1842. In miniated to the office of grand master. In mointain James Lin m encouragement must have been productive of the most

888

history of Musonry from the earliest times, beginning with Adam, and comprising quotations from some rabbinical tales, respecting the building of the tower of Babel and the temple of Solomon, limited, however, to the information contained in the Bible. It then passes over to the Greeks and Romans, mentioning particularly Pythagoras, Euclid, and Vitruvius. Then we are told that St. Albanus, an honourable Roman knight, patronized the art about A.D. 300, settled the fundamental institutions of the Masons, procured them employment, wages, and a charter from the emperor Carausius, according to which they might form a society in Britain under the government of architects. The devastation of the country, and the destruction of the edifices by the northern tribes, and destruction of the edifices by the northern tribes, and the Angles and Savons, is related; and how the pious athelstan had resolved to restore the ancient and venerable society. By virtue of this charter, all the Masons in the kingdom were assembled, and they established a general, or grand lodge, for their future government. Under the patronage and jurisdiction of this ledge, the fraternity very considerably increased. Freemasonry was first introduced into Scotland by those architects who built the abbey of Kilwinning; and the Kilwinning lodge is the most ancient in that country. After the establishment of the York and Kilwinning lodges, the principles of Freemasonry were rapidly diffused throughout beth kingdoms, and other lodges were erected in different parts of the island, lodges were erected in different parts of the island, which remained under the jurisdiction and control of which remained under the jurisdiction and control of the two mother-lodges. In this way, Masonry con-tinued to flourish in this country for several centuries after it had ceased on the continent; for the Church had come to regard them with suspicion, as being possessed of a power and influence which might, in time, be turned against itself. In this country, an act was passed against them in the third year of Henry III., at the instigation of the bishop of Winchester, which, however was naver enforced; and the king himself be use ausugation of the bishop of Winchester, which, bowever, was never enforced; and the king himself afterwards countenanced them with his presence. James I. of Scotland was also a great patron of the craft. Long before this time, however, the order had ceased to be confined to architects or builders; and noblemen, gentlemen, kings, and princes wards careful. ceased to be confined to architects or numbers; and noblemen, gentlemen, kings, and princes, were enrolled among its members as "accepted Masons." Among those who have held the office of grand master, may be mentioned Henry VII., Cardinal Wolsey, Inigo Jones, and Sir Christopher Wren. After a time, the society of Masons decreased, and sank more and more. In 1717, an entire change was effected in the constitution, and while retaining the name and customs of the tion, and while retaining the name and customs of the ancient fraternity, the society ceased to be connected with building: but for brotherly love and mutual aid. with building; but for botherly love and mutual and. The same year, the first regular grand lodge was formed in London, with power to grant charters for the holding of other lodges. The "Book of Constitutions," drawn up by James Anderson, and based upon the "Gothic Constitutions" of 926, for the use of upon the "Ground Constitutions of 220, 107 and use of the lodges, was published in 1723; and averal editions have since been published. Since that time, Masonry has continued to flourish, and at present the grand lodge of England has upwards of 1,000 lodges under its jurisdiction. It is possessed of great wealth, and distributes several thousand pounds annually for philanthropic purposes; contributing, among other things, to the support of a Masonic girls' school, established in 1788; a Masonic boys' school, established in 1798; a benevolent fund for aged Masons, established in 1842; and a widows' fund, established in 1850. In Scotland,

## Free Spirit

without payment of any duty, and afterwards either re-exported on payment of mere transit duty, or ad-mitted for consumption on paying the usual customs dues.

FERE SPIRIT, BRETHERN OF THE. (See BRETHREN OF THE FREE SPIRIT.)

FREESTONE, free'score (Sax. stan, stone), in Build., the name generally given to any soft atone that can be readily sawn and worked with the mallet and chieel. The various kinds of stone that come from the quarries near Bath, and those near Portland and in the Isle of Purbeck, are freestones; and some kinds of lime-stone are also included under this term, as well as soft sandstones and colites, smong which may be named the magnesian limestone used in building the new palace at Westminster and the houses of parliament.

FREETHINKER, free-think'-er (Sax. thincan, to think), is a term applied to one who exercises freedom of thought, and is generally used in a bad sense to denote one who is sceptical on matters of religion.

DRISM, ATREMEN.)

FREE TRADE, free traid (Sp.-Port. trate, trade), in Pol. Boo., denotes the freedom of buying and selling without any interference by way of improving or otherwise influencing trade. It is only lately that our government has come to see the importance of this manifolds and that all attempts to enougage contains principle, and that all attempts to encourage certain branches of trade and discourage others are detrimental and injurious. (See Corn Laws, Customs Duties, Bounty, Balance of Trade, Political

BOTTIS, BOUNTY, BALANCE OF TRADE, POLITICAL ECONOMY.

FREE WILL, FREEDOM AND NECESSITY, LIEFETY AND NECESSITY, free will, free-dom, ne-sed-c-te, liberts, liberts, liberts, liberts, liberts, liberts, liberts, in Phil., are terms employed to denote one of the most difficult questions in the whole field of mental science,—the power of a man over the determination of his own will. "If," says Reid, "in any action he had power to will what he did or not to will it, in that action he is free. But if in every voluntary action the determination of his will be the necessary consequence of something involuntary in the state of his mind, or of something in his ext circumstances, he is not free; he has not what I call the liberty of a moral agent, but is subject to neces-Freedom has commonly been distinguished into freedom from coercion and freedom from necessity. Freedom from coercion implies, on the one hand, the Areadom from coernon impaces, on the one name, the absence of all impediment or restraint, and on the other hand, the absence of all compulsion or violence. Thus, if we are prevented from doing what is in our power when we desire or will to do it, or if we are compelled to do it when we desire and will not to do it. we are not free from coercion. Freedom from neces sity, called also liberty of election, implies freedom from anything invincibly determining a moral agent. This freedom from necessity, however, does not mean that the agent has no motive or no more inclination towards one course of action than another; for he may have motives prompting him more urgently to act in one direction rather than in another, and still have liberty of election, if he has the power of determining in favour of another course of action. The universal language and practice of mankind is founded upon a belief in a kind of free will. To choose, to deliberate, to determine, are expressions in every man's mouth; and the whole of our penal code is founded upon the conviction that men have the power of doing or abstaining from certain acts. But if we examine the matter more closely, and look at the particular acts of one's life, we will find that this freedom of choice does not actually exist to the extent that we might at first sight be inclined to suppose. We find that if we know the "corcumstances and character of an individual, we can calculate pretty correctly how he will act in a given case. A man's habits, his education, his character, all go in some measure to determine his acting in a given case in a particular way. Hence, therefore, every sot of the will, in some degree at least, depends upon something going before, or in the circumstances of the individual; and in so far it is not absolutely free. "What," says Coleridge, "determines the man to a "What," says Coleridge, "determines the man to a good and worthy act, we will say, or a virtuous course of conduct? The intelligent will or the self-determining power? True, in part, it is; and the will is pre-

## Freezing Apparatus

eminently the spiritual constituent in our being. But will any man admit that his own will is the only and sufficient determinant of all he is and all he does? Is nothing to be attributed to the harmony of the system to which it belongs, and to the pre-established fitness of the objects and agents, known and unknown, that surround him, as acting on the will, though doubt-less with it likewise?" The whole question, howsurround him, as acting on the will, though doubt-less with it likewise?" The whole question, how-ever, is involved in difficulties which defy our limited faculties to solve. "How the will can possibly be free," says Hamilton, "must remain to us, under the present limitation of our faculties, wholly incompre-hensible." "The assertion of absolute necessity is virtually the negation of a moral universe, conse-quently, of the Moral Governor of a moral universe, in a word, atheism." "It would have been better," he said, in speaking of the view of the question as taken by the Scottish school of philosophers, "to show articulately that liberty and necessity are both incomtaken by the Scottish school of philosophers, "to show articulately that liberty and necessity are both incomprehensible, as both beyond the limits of legitimate thought; but that, though the free agency of man cannot be speculatively proved, so neither can it be speculatively disproved; while we may claim for it as a fact of real actuality, though of inconceivable possibility, the testimony of consciousness,—that we are morally free, as we are morally accountable for our actions."—Lectures on Metuphysics.

FINEZULO, FRONT, freezi-jun, front (App. Sax.), the

FREEZING, FROST, freez'-ing, frost (Ang.-Sax.), the solidification or congelation of water or atmospheric vapour by cold. Water begins to freeze when the temperature of the atmosphere is 32° Fahr., at which point ice begins to appear, and continues to be formed, point ice begins to appear, and continues to be formed, unless some circumstance, such as the disturbance of the water, interferes. As the cold increases, other liquids, which are able to resist the temperature at which water congeals, begin to freeze, and pass into the solid form. During spring and the early months of summer, much harm is done to vegetation by frost; and during severe frosts almost all vegetables fall into a state of decay, and even a moderate frost is able to destroy tender plants. When there has been much rain, and when the plants are saturated with moisture, the occurrence of a frost is very disastrous; for as the water contained in the leaves begins to freeze, it exwater contained in the leaves begins to freeze, it expands, rupturing the vegetable fibres and destroying the plant. Fruits are destroyed by frost in a similar manner. When the morning dew freezes, it is called nanner. When the morning dew ireczes, it is caused hoar-frost, or white-frost, and appears generally in spring and autumn. As the air begins to be warmed by the rising sun, the evaporation from the leaves of grass, plants, and shuubs, is accelerated, and the cold increased; hence the moisture which was only dew before the dawn, is often converted into hoar-frost shortly after sunrise. The disastrous effects of frost upon vegetation can only be averted in a very limited manner. That which will protect a plant from dew will protect it from frost; hence a covering of network or thin gauze will protect tender plants or the blossom of wall-fruit. The most efficient mode, however, is to shield the plant from the clear sky, and thus prevent the radiation which must otherwise take place

place.
FREEZING APPARATTS, a contrivance by which liquids are frozen artificially. The first apparatus of the kind was one invented by Sir John Leelic, by means of which liquids were frozen in racue. When the pressure of the atmosphere is removed, liquids evaporate much more rapidly than under ordinary circumstances, the heat producing the evaporation existing in the liquids themselves. When, therefore, accounting submires other in placed in a reseal under existing in the liquids themselves. When, therefore, a quantity of sulphuric ether is placed in a vessel under the receiver of an air-pump, and in it is placed a vessel containing a small quantity of water, on exhausting the receiver, the ether eraporates rapidly, and, in so doing, abstracts the latent heat of the water, which is soon converted into ice. Leslie introduced into the receiver a shallow vessel containing highly concentrated receiver a snation vessel containing highly concentrated sulphuric acid, abore which was placed another vessel containing water; when the air was abstracted, the water evaporated rapidly, and its vapour, on account of the strong attraction which sulphuric acid has for it, was immediately absorbed. In two or three minutes congelation began. Sulphuric acid is not the only substance which is capable of producing this result; any substance which has a strong attraction for water

Fahr.

## Freezing Mixtures

will do as well. Dry potash, muriate of lime, or powder of basalt, are sill used for the purpose. A number of machines of this kind, varying in many ways, have since been constructed. One of the most encessful produced large blocks of ice by the evaporation of ether, and another welded slabs of ice as fust as tion of ether, and another weided since of the sa risk is they were formed. A detailed account of the former, which was patented by Mr. Harrison, is to be found in the "Pharmaceutical Journal," xvi. 477. Its principle generally, is the production of cold by evaporating volatile liquids in vacuo, the condensation of their vapours by pressure, and the continued re-evaporation and reactions of the same material. and re-condensation of the same material.

FREEZING MIXTURES (in Chem.). - Many salts, while undergoing solution, produce a very considerable reduction in the temperature. By mixing 4 oz. of nitre and 4 oz. of sal-ammoniac, and throwing them into water, the temperature is reduced from 60° to 10°; and a mixture of equal parts of water, nitrate of ammonia, and carbonate of soda, the two latter in the crystallized condition, is capable of effecting a reduction from 50° to 7°. Equal parts of snow and salt will maintain a steady temperature of -4° for many hours; amanusan a sceany temperature of -6" for many hours; and if a mixture of three parts of crystallized chloride of calcium and two of snow be made, in a vessel cooled down to 32°, a cold of -50° will be the result. The following are a few freezing-points that may be found useful:—

Mercury	-39°
Mercury	-30°
Bromium	4°
Saturated solution of chloride	
of sodium	40
Sea water	28°
Pure water	320

FEREZING-POINT. (See THERMOMETER.)
FREIGHT, frait (Du. vragt, Ger. fracht), in Com., is the money paid for the carriage of goods by sea, or the price paid by a merchant for the use of a ship to transport goods: the word freight is also sometimes used as synonymous with cargo. When an entire vessel is engaged for the transport of goods, there is usually an instrument executed known as a charterusually an instrument executed known as a charter-party, in which the terms of the agreement and amount of freight are set forth. If, however, merely a part of the ship is engaged, or a certain amount of goods to be conveyed, there is usually a bill of lading made out. Where no formal agreement is entered into, the amount of freight is regulated by the custom or usage of trade. The freight is most commonly determined for the whole waver without respect to time, but for the whole voyage, without respect to time; but sometimes it is made to depend upon time. In the former case it is either fixed at a certain sum for the whole cargo, or at so much per ton, barrel, bulk, or other weight or measure; or so much per cent. on the value of the cargo. The time and manner of paying the freight are frequently regulated by express stipu-lations in the charter-party or other written contract. The master is entitled to detain the goods until the freight has been paid; but the master cannot retain the cargo on board till such payment, as the merchant would in that case have no opportunity of examining the condition of the goods. No right of lien for freight exists unless the freight be earned; but if the freighter or a stranger prevent the freight from befreighter or a stranger prevent the freight from be-coming due, the owner or master has a remedy by ac-tion of damages. When goods are deteriorated during a voyage by fault of the master or mariners, the owner is entitled to compensation; but if from natural causes or perils of the sea, the owner must bear the loss and pay the freight. The merchant, however, cannot set off his claim for damage against the amount of the freight, which must first be paid, and the merchant may then substantiate his claim to compensation for the dewage If a vertion of the search by the the damage. If a portion of the cargo be thrown the damage. If a portion of the cargo be thrown overboard for the necessary preservation of the ship, and the rest reach its destination, the owner is bound to answer to the merchant, by way of general average, for the value of that which was lost, as the freight is to be paid to the owner. Legally, no freight is due until the voyage is completed, which, however, may be overraled by express stippistion. If a merchant covenant to freight a whole or a certain portion of a ship, he is bound to pay the sum stipulated for, though

## French Language and Literature

his goods do not occupy the entire space. Where the freight is to be paid for the voyage, the owner takes upon himself the risk of its being long or short; where upon himself the risk of its being long or short; where by the time, the risk falls upon the merchant. As regards living animals, if the ship be freighted for transporting them at so much a head, freight is only due for such as are delivered alive; but if for Lading them, it is due for all that were put on board. Where there is no express agreement, the law holds that freight is due for the dead as well as the living.—Ref. Abbott's Law of Shipping; McCulloch's Commercial Dictionary. FRENCH BERIES. (See RHAMNUS.)
FRUNCH CHALK. Freight hishauk, a kind of soap-stone

FRENCH CHALE, frentsh tshawk, a kind of soap-stone of a soft and greasy nature, known by that name, and sometimes called Briançon chalk, because it is obtained of france. It forms a white pigment when properly prepared, and is much used by tailors in marking the pattern of garments on cloth, before cutting them out, as the marks made can be easily obliterated, and cause

no injury to the material.

FRENCH Honn, frontsh horn, a wind instrument, consisting of a long tube twisted into several circular folds, gradually increasing in size from the mouth-piece to the bell, or end at which the sound issues. As it is not provided with holes, like the flute, its sounds are varied by the lips of the player, the greater or lesser pressure of his breath, and the insertion of the hand into the bell, or end from which the sound issues; it may also be tuned to a variety of keys, by means of crocks and shanks, or movable pieces added to, or removed from, the top of the tube, as required. The introduction of the horn, in common with that of the trumpet, dates less than a hundred years ago. Since then it has undergone many changes, and within the last fifty years the whole of this class of instruments have been greatly improved by the addition of keys, valves, crooks, &c. gradually increasing in size from the mouth-piece to

by the addition of keys, valves, crooks, &c.
FRENCH LANGUAGE AND LITERATURE.—The origin of the French language is to be traced to three distinct sources,—the Celtic, the Latin, and the German. Of the Celtic, or earliest of these, the language of the country prior to the Roman invasion, comparatively few traces are to be found in that of the present day. When the prior to the Roman invasion, comparatively few traces are to be found in that of the present day. When the country came under the dominion of the Romans, the Latin being the language of the conquerors, came, by degrees, to be that of the people generally. Not, however, the classic form of that language, which is met with in authors, but a corrupt dialect of it, known as the lingua Romana rustica. On the overthrow of the Western Roman empire, this language became corrupted by the admixture of words and expressions from the Rusquadien Visicathic Emphasis and other large rupted by the admixture of words and expressions from the Burgundian, Visigothic, Frankish, and other barbaric tongues. In the 7th century, two forms of speech prevailed in the country—a corrupt dialect of the lingua Francisca or Theotisca, or the Tudesque. The latter prevailed in the north and east parts of the country, and the former was spoken south of the Loire. The council of Tours (813) recommended the use of both the Rustic and Tudesque versions of the homilies. In course of time these two became in some measure blended, the Latin element remaining the more promished the Latin element remaining the more promished. blended, the Latin element remaining the more prominent; and this corrupt language was called the Romance. It was divided into two branches, which took their names from their respective modes of expressing the word yes. The Visigoths and Burgundians south of the Loire said oc (Latin ac, German auch, also) for y while the Franks and Normans to the north said oil; and hence the dialect of the former was called la langue d'oc, and of the latter la langue d'oil; the former of these, which came to receive the name of Provençal, from the kindgom of Provence, which at one time included the whole of the south of France, was characterized rather by a modification of Latin words, than by the admixture of foreign words and idioms. Though much changed, it is still the dialect of the common people in Provence, Languedoc, Catalonia, Valentia, people in Provence, Languedoc, Catalonia, Valentia, Majorca, Minorca, and Sardinia. Less troubled by wars, and of a more gay and sprightly turn of mind, the language of the southerns speedily became pollshed, and its glory was spread over Europe by the labours of the Troubadours. The dialect of northern France had a much greater admixture of the Germanic element than the south, which was still farther augmented by the establishmest of the Normans in that part, in the

## French Language and Literature

French Language and Literature

beginning of the 10th century. The Trouvères of the North, at a later period, in their ruder tongue, followed the example of the Troubadours;—but while the latter sang the soft strains of love, the former celebrated deeds of war and chivalry. After the commencement sang the soit strains of love, the former celebrated deeds of war and chivalry. After the commencement of the Crusades, both languages approached towards a fusion. The cruel persecution of the Abigenses checked the development of the Provencal language; and the extending of the political rule of the north southwards, brought with it the language of that people. The real French language began to be developed about the time of the conquest of Constantinople by the French Crusaders, at the beginning of the 13th century, is the earliest work in genuine French,—French which is quite intelligible to the student of the present day. Francis I. greatly encouraged the development of the French, and substituted that language for Latin in public transactions. Rabelais greatly enriched it; Ronsard and Du Bellay, Amyot and Montaigne, and others, developed it still further. The religious reform, political troubles, the influence of the Italian wars and queens, modified it greatly. The introduction of Arabic words is chiefly due to the Crusades; and of Greek and Latin words, and of scientific terms, to the study of these languages and to the outtivation of the transactions of the lating the strains of the study of these languages and to the outtivation of the transactions. Greek and Latin words, and of scientific terms, to the study of these languages and to the cultivation of the natural sciences. The Académie Françoise, established by Richelieu for the regulation of the national language (1635), the influence of the court, the labours of the Port Royalists, especially Pascal (1666), and a galaxy of great writers, purified, augmented, and diffused it more and more. It was first used as a diplomatic language at the conferences of Nimeguen (1678). The French is the most generally known of all languages among civilized actions. and many illustrations foreign. among civilized nations; and many illustrious foreign-ers, as Leibnitz, Humboldt, Gibbon, and Sir William-Jones, have written some of their works in it. It is a very clear tongue, on account of the strictly logical order of its syntax, but very monotonous, and incapable of the composition of words already fixed, as well as of bold poetic turns. The French language, in short, is, like every other, the exponent of the nationality, like every other, the exponent of the nationality, vicissitudes, intelligence, culture, and taste of the people that speak it. The earliest literature of France is that of the Troubadours and Trouvères. The former flourished most during the 11th and 12th centuries. Their productions were chiefly short lyrical effusions on love or matters of trifling import; and they exhibit little play of the imagination, little depth of emotion, and very slight traces of learning. The Trouveres, on the other hand, in their narrative poems known as Chansons de geste, and written in the energetic langue d'oil, treated of great national subjects, and celebrated the heroic deeds of illustrious kings and knights. Some of their corrections are subjects. of their compositions, especially the earlier, have a striking character of grandeur, which may sometimes be not unfavourably compared with that of the ancient epic poems. These chansons de geste, also called ramances, are very numerous, and have been classified into three cycles, bearing respectively the names of Char-lemagne, King Arthur, and Alexander,—the first cele-brating the deeds of the great Frankish emperor, his descendants and vassals; the second comprising traditionary legends regarding the achievements of King Arthur of Britain and the Norman warriors; the third consisting of poems in which events in the history of Greece and Rome are strangely mixed up with chival-ric notions and legends of fairy-land. These were succeeded by satirical and allegorical poems of equally ric notions and legends of fairy-land. These were succeeded by satirical and allegorical poems of equally rast proportions, some of which enjoyed unparallelong popularity; such as the "Roman de Renard," and the "Roman de Renard," and the "Roman de la Rose." The former is the well-known story of "Reynard the Fox," the "Reinecke der buchs" of the Germans; the latter is a poem of 22,000 verses, 4,150 of which were written by Guillaumed the work was completed fifty years later, by Jean de Mean. This is, perhaps, the most celebrated French man from the most of the 13th century; and the work was completed fifty years later, by Jean de Mean. This is, perhaps, the most celebrated French prose. Such was the opening of the splenderd, of the middle ages. It is a kind of didactic louis XIV., and which is generally styled the Age of production of the middle ages. It is a kind of didactic louis XIV., and which is distinguished by a galaxy of sulegorical poem, which professes to teach the art of the middle ages. It is a kind of didactic louis XIV., and which is distinguished by a galaxy of superior intellects, who, under the royal patronage, love, and embraces the most varied subjects. It contains a great deal of learned lore, scholastic subtleties, and embraces the most varied subjects. It contains a great deal of learned lore, scholastic subtleties, and embraces the most varied subjects. It contains a great deal of learned lore, scholastic subtleties, the did iterary epoch which is generally styled the Age of the most varied subjects. It contains a great deal of learned lore, scholastic subtleties, and embraces the most varied subjects. It contains a great deal of learned lore, scholastic subtleties, who, under the horges in the improvement of its language. Fierre Cornellies tragety to a degree of grandeur which has nought to every because, "Le Cid," "Chorce," "Cinna," and "Pledred, and 886

of oriental origin, and were introduced by the Cruanders into Europe. They are usually written in verse, but sometimes in prose and verse alternately; and are generally based upon some well-known proverb, anecdote, or adventure, often containing a great deal of wit or fun, being generally satirical in their character; they are, however, frequently distigured by a coarse licentiousness. Songs were not neglected; and those of the illustrious Abelard, in the 12th century, enjoyed a wide popularity. The progress of prose was slower than that of poetry; but the 13th century presents two specimens, showing that it had already acquired a degree of power and polish. These are the "Chronicle of the Conquest of Constantinople," by Villehardonin (1207), and the interesting and simple Life of St. character; they are, however, frequently distigured by ple," by Villehardouin (1207), and the interesting and simple Life of St. Louis, written by Joinville, who tells us of the heroic deeds and private virtues of the good thing, whom he had accompanied to the Holy Land.
In the latter half of the 18th century we also find some tolerably good specimens of the drams in the Mysteries and Moralities of that period. The whole of the teries and Moralities of that period. The whole of the literature of the 14th century culminates in Froissart's "Chronicles," which present the liveliest pictures of society and manners during that period of war and gallant enterprise. The greatest writer of the 15th century, also a chronicler like Froissart, is Philippe de Comines, who in his "Mémoires" presents a striking delineation of the characters of Louis XI. and his contemporaries. To the same period belong two of Franco's distinguished noets, who, strange to say, pre-France's distinguished poets, who, strange to say, pre-sent a striking contrast to each other in their outward circumstances, the one the princely Duke Charles of Orleans, the other the low-bred and lawless Villon, a strange compound of villainy and inspiration. A new epoch in the history of French literature begins with the reign of Francis I. (1515). The study of Greek and Roman authors now began to prevail in France; and writers, dazzled by the hitherto unknown beautics of the classical writers, despised the works of their forefathers, and attached themselves to the imitation forefathers, and attached themselves to the imitation of the ancients. Thus arose the so-called modern classical school; while that which, instead of imitating the ancients, derived its materials from national elements, has been designated by the appellation of Romantic. Tolerably free from the classic element are the works of Clement Marot, the greatest French poet of the reign of Francis I; while the leader of the new or classical school was Ronsard, an author long extolled far above his merits. A host of other writers characterize this century, chief among whom are Rabelais and Montaigne. In the 17th century Malherbe anneared as the reformer, or rather the regulator, of appeared as the reformer, or rather the regulator, of poetry, a man of fastidious taste but meagre imaginawho despised the artistic luxuriance of Ronsard, tion, who despised the artistic luturiance of Monard, introducing in its stead a style of grammatical correctness and dry elegance, which sometimes reached pomposity. Balzac devoted his attention to the improvement of proce, and his semi-philosophical works, especially his Epistles, were valuable at the time as models of careful and harmonious style. Such were also the frivolous but witty letters of his friend Voiture. In 1634 the French Academy was instituted, under the auspices of Cardinal Richelieu, "to establish certain rules for the French language, and to make it not only elegant but capable of treating all matters of art and acience." Three writers of this period enriched French literature with important works, and did much towards the improvement of its language. Pierre Corneille

## French Language and Literature

remind one of the productions of ancient Greece; while comedy reached its highest pitch with Molière, whose masterpieces, "Le Misanthrope," "L'Avare," and "Les Fernmes Savantes." are very humorous creations. In his Fables, La Fontaine showed himself the greatest master of that kind of composition in modern times. Didactic poetry was represented by Boileau, whose works are remarkable for symmetry and good same but are articly deficient. represented by Bolleau, whose worse are remarable for symmetry and good sense, but are entirely deficient in poetical enthusiasm. Moral philosophy was cultivated by Malebranche, the disciple of Descartes, and author of "La Recherche de la Vérité;" by Bossnet, who wrote "Conneissance de Dieu et de soirmème;" by Fonclou, as in his treatise "De l'Existence de Dieu; and by Pascal, in the fragments which have been col-lected under the title of "Penaces;" while La Roche-foucauld, in his "Sentences et Maximes," wrote a libel upon maukind, and La Bruyère, in his "Caractères," drew vivid and amusing sketches of human characters and manuers. In the field of history, we also meet with Bossuet, as the author of "Discours sur l'His-toire universelle," and "Histoire des Variations des with Bossuet, as the author of "Discours our Littles toire universelle," and "Histoire des Variations des Eglises Protestantes." Here, too, we have Mézeray, author of the "Histoire de France," and Fleury, author of "Histoire de l'Eglise." In memoirs and letters, there are the personal "Mémoires" of Cardinal De Retz ; Hamilton's "Mémoires du Comte de Grammoot; and the interesting letters of Madame de Sé-vigné to her daughter and friends. The 17th century had been, on the whole, a religious one; but the 18th was eminently an ago of scepticism and infidelity. Literature now became a means of conveying bold opinions, or assaulting time-honoured creeds and institu-The persons who exercised the chief sway during this period, and who exerted a powerful influence upon their contemporaries, were Montesquieu, Voltaire, J. J. Rousseau, and Buffon. Montesquieu, a writer of great force and brilliancy, and of unusual scope of great force and brilliancy, and of unusual scope of mind, commenced his literary career by publishing "Les Lettres Persanes," attacking French manners, institutions, and even religion. His principal works, however, are his "Considerations sur la Grandeur et la Décadence des Romains," and his "Esprit des Lois," an able and profound disquisition upon general legislation. Voltaire, the true personation of his age in disposition, as well as in talents, was, for half a century, the leader of public opinion in France. His wonderful versatility enabled him to treat successfully almost all branches of literature,—tragody, satire, romance, poetry, history, and philosophy. The passionate eloquence of Rousseau made him be listened to and believed in, even when he was declaring war ate eloquence of Rousseau made him be listened to and believed in, even when he was declaring war against civilization, and attacking the social order of things. Buffou occupied a less-sigitated sphere, devot-ing himself to the study and description of nature; and, by his "Histoire Naturelle," he introduced a new era in the study of natural history. Diderot and D'Alembert founded the "Encyclopidie," a vast re-view of human knowledge, but always bestie to assis. D'Alembert founded the "Encyclopédie," a vast review of human knowledge, but always hostile to religion. Helvetius, in his treatise "De l'Esprit;" D'Holbach, in his "Système de la Nature;" and Lametterie, by his "L'Homme Machine" and "La Vie heureuse de Sôncauc," far exceeded the encyclopedists in the destructive tendency of their destructive tendency of their destructive. destructive tendency of their doctrines. Among the few defenders of revealed religion during the period was J. Vernet. Among the metaphysical writers, the first place is due to Condillac, followed by Van the first piace is due to commen, amount of Geneva, all of whom remained on the side of moderation, and save little support to the tendencies of the age. One of whom remained on the side of moderation, and gave little support to the tendencies of the age. One of the most learned historians of that period was Mably. Charles de Brosses, Goguet, Barthélemy, Raynal, De Mehegan, Velley, are also names of note in this department. The mathematical and physical in this department. The mathematical and physical sciences made great progress in France during the sciences made great progress in France during the 18th century; as witness the names of D'Alembert, Lagrange, Lalande, Lacaille, Maupertuis, Clairaut, Lemonnier, Condamine, and others. In natural history, we have Butfon and Charles Bonnet, Brisson, Viog d'Azyr, Jussieu in botany, and Saussure in geology. In poetry, the drama, and general literature, we may mention the names of Crebillon and Ducis, both tragic poets; Le Sage, author of "Fill Blas" and of "Turacaret," perhaps the best comedy after those of Molère; Beaumarchais, author of the "Barbier de Se-

## French Language and Literature

ville;" Bernardin de St. Pierre, author of "Paul et Virginie;" St. Simon, whose "Mémoires," have gained: a deserved celebrity; Marmontel, the author of "Bélisaire," and Lebrun, the lyric peet. The period of the Revolution was by no means favourable to literature, and little more so was that of the Empire which succeeded. Madame de Stael and Châteaubriand were the forerunners of a revival, which was, perhaps, less owing to their works than to the influence upon public tasts of the master-pieces of English and German literature, which found more and more admirers in France. A new romantic school new sprung up; and, through the exertions of many young and original writers, new life was infused into nearly every branch of literature, poetry, history, philosophy, and the drama. An animated controversy was maintained between the supporters of reform and the adherents of the classical sc hool; and the contest reached its utmost the classical school; and the contest reached its utmost fury when Frédéric Soulié, Alexandre Dumas, Victor Hugo, Alfred de Vigny, and others, produced on the stage dramas framed according to their ideas of the Shakespearean style. It was only after several years that the younger body of combatants came out victo-rious. Novels which, during the excitement of this-counter had been analyzatived beaumath. rious. Novels which, during the excitement of thiscontest, had been scarcely noticed, became the rage soon after it was settled. George Saud (Madame Dudevant), one of the most elegant writers of her country, established her character by her "Indiana," which appeared in 1832; and has since published many popular works. Alexander Dumae, the inexhaustible story-teller, has won immense popularity by his works, "Trois Mousquetaires," "Le Comte de Monte Christo," and numerous other works. Eugène Suc (Christo," and numerous other works. Eugène Suc also obtained great popularity from his works "Les also obtained great popularity from his works "Les also obtained great popularity from his works as "Heich depict in glaring colours the miseries and depravities of society. Among other distinguished writers, we may mention Honoré de Balzac, Frédérie Soulié, Almay mention Honoré de Balzac, Frédérie Soulié, Alphonse Karr, Alfred de Musset, Prosper Mérimée, Madame Emile de Girardin, Théophile Gautier, Jules Sandeau, and Emile Souvestre. A new generation of storytellers has been rising within the last few years, who, though their powers are scarcely to be compared who, though their powers are scarcely to be compared with those of their predecessors, are nevertheless not devoid of talent. Some of them belong to what they themselves call the "realist school;" they are Henri. Murger, !Alexandre Dumas fils, Champfleury, Ernest Paydeau, Gustave, Faubert, Octave Feuillet, and Edmond About. Poetry is far from being as popular in France as the novel, and the country has produced few great poets during the present century. The four greatest poets are Béranger, Victor Hugo, Lamartine, and Alfred de Musset; besides whom, Casimir Delavigne, Auguste Barbier, and Victor de la Prade, over the only names requiring to be mentioned. History is, tigne, Anguste Darbier, and victor de la France, brethe only names requiring to be mentioned. History is, undoubtedly, the most successful branch of modern French literature. A larger number of valuable historical works has been published within the last thirty-five years than during any other equal period of its history; and the taste for such performances is still on the increase. M. Guizot, the great philosophical expounder of social institutions, and Augustin Thierry, the artistic historian of the middle ages, stand foremost among the promoters of this movement. Sismondi, Michelet, and Henri Martin, have each devoted their efforts to a full recital of the general history of France; while De Barants, after giving, in his "Histoire des Duce de Bourgogne" (1824), an attractive specimen of purely marrative history, has recently published histories of the Convention and the Directory, in which his monarchical tendencies are strongly apparent. The revolutionary period has engaged the attention of many historians; among whom the most prominent are Thiers, Mignet, Michelet. engaged the attention of many historians; among whom the most prominent are Thiers, Mignete, Minchete, and Louis Blano. Lemartine also figures among the historians, having produced several works of that class, which, however, are more remarkable for their showy language than for their accuracy or research. The elegant and accomplished Villemain, although better known in the field of literature, has also preduced several bistorical works as his Wistorians. also produced several historical works; as his "Histoire-de Cromwell," and his "Sourenirs Contemporains."

As a lecturer and a critic, no man has contributed more to the diffusion of enlarged literary doctrines, healthy principles, and good taste. Archaeology has

not heen neglected; as is evinced by the works of Letrone, Racul Rochette, and Beulé. Champollion, Sylvestre de Sacy, Ernest Renan, and Abel de Rémusat have thrown great light upon Egyptian and oriental languages and literature. In philosophy, Victor Cousin and his disciples have, under the name of Eelectism, brought back the materialism of the preceding age to spiritualist principles. Jouffroy, Damiron, and Jules Simon are among those who have contributed to this Simon are among those who have contributed to this result. As writers on politics and political economy, are Joseph de Maistre, Bonald, Ballanche, Lamennais, Miobel Chevalier, De Tocqueville, and Laferrière; while as socialists, figure the names of St. Simon, Fourrier, and Pierre Leroux. Auguste Comte, in his "Cours de Philosophie positive," offers a connected system of philosophy, embodying ideas derived from Hegel and various of the French socialists. The various branches of natural philosophy bases of matural philosophy bases of matural philosophy bases of matural philosophy bases of matural philosophy. of natural philosophy boast of many original and powerful writers. In natural history, are Cuvier, Geoffroy St. Hilaire, Isidore St. Hilaire, and others; mineralogy boasts of Elic de Beaumont, Bendant, and Dufrenoy; bossts of Elie de Beaumont, Bendant, and Dulrenoy; and chemistry and physics, of Thénard and Dumas, Gay-Lussac and Despretz. In medical literature, are the names of Bichat, Broussais Corvisart, Magendie, Trousseau, and many others. The mathematical sciences have distinguished representatives in Lagrange, Laplace, Ampère, Biot, and Arago. The French essayists and literary critics are legion, and some of they here attained each still content of the conte essayists and interary critics are legion, and some or them have attained great eminence; among whom we may mention Sylvestre de Sacy, St. Marc Girardin, Philarète Chasles, Ernest Renau, Hippolyte Rigaud, Gustave Planche, Ste. Beuve, Charles de Kémusat, Albert de Broglie, Edmond About, Théophile Gautier, Léon Delaborde, and Jules Janin, the dramatic feuilletonist. For the last few years, however, French literature has been on the decline. The literary move-ment, which commenced with the Restoration, seems to be now nearly exhausted; and although there has been little falling off in intellectual activity, the rising generation of writers are not on the whole equal to their predecessors.—Ref. Histoire littéraire de la France, by Dom Rinet, and other Benedictine monks, continued by members of the Institute, 22 vols. (1733-1858); Histoire littéraire de la France avant 1133-1646; † Motore merdere de la Trance acant 1-12 Siccle, by Ampère; Tableau de la Littérature au Moyen Age, by Villemain (1857); Essais sur l'Histoire littératre du 16me Siècle, by Girardin and Chaeles; Histoire de la Littéraire Française, by Demogest

FRENCH-POLISHING, a method of polishing flat surfaces with a solution of gum or gum-resin in spirit. For this purpose the polish is made more fluid than the hard-wood lacker used in polishing turned surfaces, in order that it may spread easily and dry less rapidly. As the friction is derived entirely from the motion of the hand in French-polishing, more time is required the nand in Frence-poissing, more time is required than in polishing turned works. There are a great many recipes for making French polish, which vary greatly, as some prefer it very thin and others tolerably thick. One of the simplest methods is to dissolve 14 lb. of shell-lac in: I gallon of spirits of wine without heat. Copal, sandrac, mastic, and gum Arabic are sometimes employed. It is usual to make

without near. Copas, sandrac, mastle, and gum Arabic are sometimes employed. It is usual to make the varnish thicker than is required for use, and to thin it down with spirit when being used.

Fernch Purple is the name applied to a beautiful colour, cliedly manufactured by MM. Guinen, Marras, and Bonnet, of Lyous. It is prepared as follows:—The lecanoric, crythic, evernic scids, &c., of the lichens, are extracted by digestion with ammonia; the mass is pressed, the solution precipitated by a mineral soid, and the precipitate collected, washed, and re-dissolved in ammonia by the sid of heat, whereby a solution is obtained, which, on exposure to the air at a temperature of 19° or 20°, generally assumes a very bright-red colour. As soon as the tint has acquired sufficient intensity, the liquid is introduced into shallow basius, and very slowly evaporate to the attach into the contact with the sir, the liquid, after a few days, acquires a very deep violet colour, which undergoes

888

and rick garnet-colour, which, when collected on a filter and washed to remove the shine mother liquid, constitutes French purple. . Bo far as regards fastness and resistance to the influence of light, French purple is certainly superior to amiline purple.—
Ref. Ure's Dict. of Arte, Manufactures, and Mines, 6th edition.

FRENZY, fren'se (Fr. frénésie, Gr. phrenitis, from phren, mind), denotes madness, distraction, rage, or any violent agitation of the mind approaching to distraction.

traction.

FREQUENTATIVE, fre-kwen'-tid-tiv (Lat.), in Gram., is a term applied to certain verbs, which denote the frequent repetition of an action.

FRESCO PAINTING, fres'-ko (Ital. freeco, fresh), the art of painting in water-colours on the surface of a wall that has just been plastered, while the plaster is still in a wait condition. Freeco painting as a wall had a wall that has just been plastered, while the plaster is still in a moist condition. Fresco painting can only be managed with success by those who are proficients in the art, as it does not admit of any degree of finish, as paintings which are executed in oil, or water-colours, on canvas or paper; and no corrections can be made, if any part of the work presents an unsatisfactory appearance when the entire painting is completed. The Romans were in the habit of colouring their walls The Romans were in the habit of colouring their walls while the plaster was still wet, to produce a ground of one uniform tint; and they added decorating in distemper colours when the surface was perfectly dry. But, although it was to new thing to cover walls when wet with colouring matter which would preserve its original brilliancy of tint unimpaired for a considerable lapse of time, yet freese painting, properly so called, cannot be considered to have been introduced earlier than the large of the lath century when the practice. cannot be considered to nave been introduced earlier than the close of the 14th century, when the practice of painting designs on the damp surface of freshly-plastered walls was adopted for the decoration of cathedrals and churches at Florence, Orvieto, Piss, and other towns in Northern Italy. Freeco painting plastered walls was adopted for the decoration of cathedrals and churches at Florence, Orvieto, Pisa, and other towns in Northern Italy. Freeco painting was subsequently practised by all the Italian painters of celebrity,—Michael Angelo, Raffaelle, and others, having left exquisite specimens of their work in this branch of art in the palace of the Vatican and many of the churches of Rome. Freeco painting seems to have taken the place of encaustic painting in the 15th century for the interior decoration of large buildings (see ENCAUSTIC PAINTING), the introduction of the former art having caused the decline of the latter. It fell into disuse about the end of the 16th century, and remained in absyance until some German painters revived the art in the decoration of a villa at Rome about 1816; and Louis of Bavaria subsequently caused many of the magnificent buildings that were exected at Munich during his reign to be adorned in this manner. Freeco painting has been used for the decoration of many of the apartments and corridors in the new palace of Westminster; and a good example may be seen in the hall of Lincoln's Inn, which covers an area at the overs the reverse that the overse and of the halling of 1700 annay feet. the hall of Lincoln's Inn, which covers an area at the north end of the building, of 1,700 square feet. It nerin end of the building, of 1,700 square feet. It may be executed on any walls covered with a coat-ing of plaster. Stone walls are, however, considered to be the worst of all kinds, as they are upt to condense the damp on their surface; while walls of brick or lath-and-plaster are the best. Frescoes should never be painted on walls built with mortar mixed with sand from the sea-shore; and every precaution should be from the sea-snore; and every precaution should be taken to prevent damp rising in walls from the ground below, by placing sheet lead, coated with pitch, between any two of the lower courses of the material of which they are composed. The frescoes at West-minster are executed on lath-and-plaster, the walls behind being covered with slate, against which battens behind being covered with slate, against which battens are fixed, to which the laths are nailed. The lime need for making the plaster, especially that of which the intonaco, or ground on which the painting is executed, is composed, should be as pure as possible, approaching as nearly as may be a pure carbonate of lime, without any admixture of iron or other mineral substances. The best limestone for the purpose found in Englandis that which is quarried on Durdham Down, near Bristol. When the stone has been calcined, the lime should be kent for some time before it tion in contact with the sir, the signal, steers lew days, blown, near littled). When the stone has been calculated as very deep violet colour, which undergoes cined, the lime should be kept for some time before it no further change, even by the action of saids. The colour solution, supersaturated by a strong soid yields a copious flocculent precipitate of a very fine from the air. If the lime is used too soon, the plaster

#### Frets

is apt to rise and break away from the surface in some places, and the toke of the colours will be injured. As freeco paintings cover 'a large superficial area, it is necessary to execute them at different times in several necessary to execute them at different times in everely allows, as much of the intonece or surface being spread at one time as the painter can donveniently colour before it begins to harden; and it is contrived, if possible, to let the joint between the work of one day and that of another correspond with the outline of a figure, or with that of the drapery that is thrown around it. It is necessary that the walls on which frasco paintings are to be executed should have the first and accord coals of plaster put on at least two or, three years before the ground is applied for the reception of the painting. Before painting, the wall must be thoroughly soaked with water, and two very thin coats of the intonece spread over it, both consisting of prepared lime and very fine river-sand, but the sand preponderating in the mixture used for the first coat. The design, of which the painter has a finished sketch already prepared, is then traced with a hard blunt tool on the intonece, from carcious laid on it, as soon as it; is hard enough to withstand the action of the brush and receive the colour. The outline having been thus produced, the colouring is applied in washes, half as hout, or rather less, being allowed to elapse between the application of the successive washes, when two or three are necessary to produce a proper depth of tint. Roundness is given to figures, and the proper effect of light and shade is produced by cross-hatching; and the whole is toned down by washes and glazes, all of which must be done while the plaster is the plaster is the most or must be careful to abstain from adding more colouring matter when he finds that the plaster is the roundness of the successive washes, when two or three are held to the done while the plaster is the most of the most of the successive when he finds that the plaster is the most of the most of the successive when he finds that the plaster is the most of the successive when he finds that the plaster is the most of the successive when he finds that the plaster is the mos pieces, as much of the intenses or surface being spread from adding more colouring matter when he finds that from adding more concurring matter when he industrial the plaster is throughly charged with moisture and unable to receive any more. The colours used are prepared from coloured earths and a few minerals, such as the oxides of iron and cobalt. Vegetable colours, or those made from animal matter, such as colours, or those made from animal matter, such as gamboge and Prussian blue, cannot be used, as lime has an injurious effect upon them. There is another kind of freeco painting, called freeco secco, or dry freeco, in which the whole of the ground is spread on the wall before the painting is commenced, the surface being moistened with lime-water before beginning to paint, and kept damp during the operation. Freecoes may be cleaned with bread or sponged with
water when the surface appears dirty; and there is a
process by which they may be detached from the wall
on which they are painted, and transferred to canvas.

of them which are to be pressed on the finger-board
with the fingers of the left hand, for the purpose of
producing certain sounds. to paint, and kept damp during the operation.

with the fingers of the left hand, for the purpose of producing certain sounds.

Falls, fri'ar (Fr. frère, brother), is a common term applied to monks of all orders, founded on the supposition that there is a kind of brotherhood existing between the religious persons of the same monastery. More particularly, it was applied to those of the mendicant orders, of which the principal were the four following:—Pranciscans, Minors, or Grey Friars; Augustines; Dominicans, or Black Friars; and Carmelites, or White Friars. In a more poculiar sense, friar is restricted to such monks as are not priests; the latter being usually dignified with the appellation of father.

of father.
FRIARS OBSERVANT (Lat. Fraires observantes), were FRIARS OBSERVANT (Lat. fratres observantes), were a branch of the Franciscane, who separated themselves from their brethren of that order, on the ground of a laxity of discipline, and lived apart in places of their own choosing. They were so called because, although not living together in any convent or corporation, they agreed among themselves to observe the rules of their order more strictly than the conventuals did.

Friction, frik-shan (Lat. frictio), in Mech., the resistance which a moving body meets with from the surface of the body on which it moves. As no surfaces are perfectly smooth, the imperceptible asperities, which may be supposed to exist ongil surface, however highly polished, become to some extent inter-

## Friendly Societies

locked, and a certain amount of force is requisite to oversome the mutual resistance to motion of the two surfaces, and to maintain the sliding motion even when it has been effected. By increasing the pressure, the resisting power of friction is increased; while, on the other hand, by rendering the surfaces more smooth, and by lubrication, the resistance to motion is diminand by lubrication, the resistance to motion is diminished, although it cannot be entirely avoided. Strictly, friction should not be called a force, except in a negative sense. In a general sense, the tendency of force is to produce motion, or, if it does oppose motion, it is only in virtue of a tendency to produce motion in the opposite direction. The peculiarity, however, of triction is, that it tends to destroy motion in every direction. Friction is essentially a passive resistance, a negative force, produced by pressure, to which it bears such relation that its amount may be measured by the same unit, and he cannot the same terms. The such relation that its amount may be measured by the same unit, and be enunciated in the same terms. The principal laws with regard to friction are as follows. Law I.—The friction bears to the pressure upon the surfaces in contact a ratio which is constant for the same materials with the same condition of surfaces. Thus if the surface of one body be pressed upon that Interest the surface of one body be pressed upon that of another with a certain force, and if that force be doubled, the friction will be doubled; if the pressure be tripled, the friction will be tripled, &c. Law 2.—The measure of friction is independent of the extent of surface, the pressure and the condition and characters of the pressure and the condition and characters of the pressure and the condition and characters. ter of the surfaces remaining the same. Law 3.—The friction is entirely independent of the velocity of con-tinuous motion. These laws, although stated in reference to the movement of two smooth surfaces, are equally true with regard to the rubbing parts of every machine. It is always found that the friction is greater

machine. It is always found that the friction is greater between substances composed of the same material than between the surfaces of heterogeneous bodies. Fairnnix Societies, of Bankeri Societies, frend-le (Sar. frend, friend), are voluntary associations of persons, whichy of the humbler classes, for the purpose of forming a fund, by mutual contribution, for the assistance of members in the case of sickness or other distress. It is acquely possible to overwate the imassistance of members in the case of sickness or other distress. It is scarcely possible to overrate the im-portance of such institutions, if founded on correct principles, either to their members or the community at large. Sickness, death, and other misfortunes, which are so uncertain in their occurrence to any one, may, when applied to a number, be made the subject of pretty accurate calculation, and thus be provided against. The poor mun, then, by contributing a small sum periodically to such a society, will have the astisfaction of knowing that he will thus have the means of meeting and high-times. raction of knowing that he will thus have the means of meeting such misfortunes, whether they come soon or late; while in this way, provident habits and a spirit of independence are fostered, and the commu-nity are saved from what might have otherwise fallen to be a burden upon them. In other words, friendly to be a burden upon them. In other words, friendly societies are mutual assurance associations. Each member contributes a certain sum weekly, monthly, or annually, while he is in health, and receives a ceror minusity, while he is in heating, and receives certain allowance or pension when incapnoitated by sickness or old age. It is to be regretted, however, that many of these excellent insultutions are founded upon erroneous principles, and have seculted in disappoint. The contingencies which require to I vided for ought to be carefully calculated, otherwise they may soon find that their funds are by no means adequate to meet the various claims that are brought against them. (See INSURANCE.) The origin of friendly societies has been traced to the guilds which existed societies has been traced to the guids which existed in the middle ages. Mr. Turner, in his "History of the Anglo-Saxons," says "The guids, or social corporations of the Anglo-Saxons, seem on the whole to have been friendly associations, made for mutual aid and contribution to meet the pecuniary exigencies which were perpetually arising from burials, legal exactions, penal mulcts, and other payments or compensations." The beneficial results that attend such associations have lest the government, from time to time, to pass statutory enactments in their favour. In 1793, an act was passed authorizing such societies to be formed, and to draw up regulations for their government, which, on being examined by the justices at quarter sessions, and found not to be repugnant to the laws of the realm, were to be confirmed and made binding upon the subscribers. They were also releved

from the payment of certain stamp duties, and ampowered, in the recovery of moneys and certain other, and powered, in the recovery of moneys and certain other, asses, to proceed by summary necess. Several acts were subsequently passed, northering still further benefits upon them, and in 1820 and 1820 which sometimes of the Rouse of Commons were supported to consider the laws on friendly-necestics. In consequence of their reports, an act was passed in 1826 (19 Geo. IV. c. 58), which reported all previous acts on this subject. This, with two subsequent acts (5 Will. IV. c. 37, and 4 £. 5 Will. IV. c. 39, established these contains on any forting, and obliged them to submit a statement of their pulses and resultaine for the approval of an officer heigs entitled to claim the benefits of those acts. It is, however, unaccessary to mention these, as the whole of the previous enauments on the subject were repealed and consolidated by 18 £ 18 Vict. c. 63. This act applies to all societies established for any of the following purposes:—"1. For issuring a sum of money to be paid on the birth of a member's child, or on the death of a member, or for the funeral expenses of the wife or while of a member, or for the funeral expenses of the wife or while of a member, or for the funeral expenses the following way.

money to be paid on the birth of a member's come,
on the death of a member, or for the funeral expenses
of the wife or child of a member. —2. For the relief,
or maintenance, of the members, their husbands,
or maintenance, or the members, their husbands,
and the members or nicoes, or maintenance, of the members, their husbands, wives, children, brothers or sisters, nephews or nicoes, in old age, sickness, or widowhood; or the endowment of members, or nominess of members, at any age.—3 of members, or nominees of members, at any age.—3. For any purpose which shall be authorised by one of her Mijasty's principal socretaries of state; or, in Scotland, by the Lord Advocate, as a purpose to which the powers and facilities of this act ought to be extended; provided that no member shall subscribe or contract for an annuity exceeding thirty pounds per annuar; for some payable on death, or any other contingency, exceeding two hundred pounds." Under this act three registrars are appointed; one for England, one for Ireland, and one for Scotland. Any persons wishing to establish a society of this description may make rules for that purpose, two copies of which must be made out and transmitted to the registrar; and when perfified by him, as conformable to law and to the said act, one of them is to be returned to the conjety, and the other is to be kept by the registrar. Upon being so certified, the rules take imto he society, and the other is so be kept by the register. Upon heing so certified, the rules take immediate effect, and are binding, in point of law, on all parties governed. "The trustee, or trustees, of such societies are required, from time to time (with the consent of the society), to invest the fund, either an action that or in the orbits. savings banks or in the public funds, or in such other manner as in the sot set forth; and all real and per-sonal situate helonging to the society shall be vested in sound state belonging to the society shall be vested in the trustee or trustees, and their successors, without any conveyance or assignation whatever, except in the case of stock in the public funds, which shall be transferred into the name of any new trustee or trustees; and in the swent of the death, bankruptcy, or insolvency of, or process issued against, any officer of the society, having its money in his hands, a priority of payment is secured to the institution. It is also provided, that if any officer of the society, or other person, shall, by false representation or imposition, obtain shall, by false representation or imposition, obtain possession of any pasperty of the society, or, having the asme in his possession, shall withhold or misapply the same in his possession, shall withhold or misapply the same in his possession, shall withhold or misapply the same; the money may be recovered, and the oftender subjected to a penalty by a summary proceeding before quotienes of the peace; and that applications for the resolution, or for the settlement of disputes (where there is no other prescribed method), shall be made to the county court of the district within which the usual or principal place of business of the society shall be estimate, and that the declation of such court shall not be simulate, and that the declation of such court shall not he subject to he made a written explication in made by at least the appeal. —(Stephen's Commentaries on the subject to he made a written explication is made by at least the sprincipal place of the areas; and it he finds the registers is to investigate the same; and it he finds the mount of the final and constitution of the final sed constitution is believed by governance, and not appealable. FRIGATE, frig-ut (Fr. frégate). Formerly, the name frigate was only known in the Mediterraneau, name frigate was only known in the Modifetraness, and applied to a long vessel or galley, propelled by oars and sait; in the present day, however, frigate signifies a fast-sailing ship of war, with two gun-decks; which lies between the two classes stoop and time of buttle skip, and which mounts any number of guns from swenty up to fifty, which latter number is seldom exceeded. All the armour-plated vessels which have been duilt have been equipped as frigates,—such as the Warrior, the Northumberland, the Adulties, &c.

Fargarane (Freque Agesles, Rey), a bird common on the intertropical American cousts, and in the Atlantic and Ferific occaus. It is allied to the commonsts, but differs from them by having a forked tail,

rants, but differs from them by having a forked tail, short feet, the membranes of which are very deeply notched, an extraordinary spread of wing, and a beak, both mandities of which are curred at the tip. The poun manufacts of wines are current at the sty. The plumage is, on the upper parts purple-black, the throat and belly white, and the besk red. The frigate-bird is incapable of either swimming or diving; yet it manuages to saviely its natural appetite for fish with tolerable certainty: this is accomplished by a system of highway robbery, perpetrated on such gamets and sea swallows as may be returning with full pouches to their nests in the rocks. The common mode is for the frigate-bird to sear above its victim, and then, plunging down, to strike it on the head with its beak; the result down, to strike it on the head within heak; the result is an instant disgorging of the day's flashing, which, as it falls, is followed by the robber, who thramably overtakes and sources it before it reaches the water. The nest of this bird is usually built among the rocks, on solitary islands, or in high trees in retired situations. FRIOD ZONE. (See ZONE.)

the Frisians is intermediate between the Anglo-Saxon and the Old North. Our knowledge of the eld Brissian is derived from certain collections of sixua; as the "Assgabuch," composed about 1200; the "Brokmerbriet," in the 13th century; the "Christian Domen," about 1300, and some officers. (But Brissian Domen, Fries. Rechtspellen, Gött, 1950.) The modern Friesan in now spoken only in 5ew districts, and some in the churchs or schools. It is further divided into a number of local dialects. Attempts have recently been made to review an interest in the Brissian, and various specimens of its earlier literature have been published. An excellent Dictionary of the old Friesan, by Richthofen, was published in 1840.

FRIENDOR'S SLASA, fride gris solve, an Icelandie myth, written down, appreently, about the end of the 13th century, but evidently belonging to a much earlier period. It marrates the surentures of the Nurregian hero Frithjof (properly Frighthejoft, i. e. peacestealer), and his love for the beautiful Ingeljörg, which some attribute to the 6th century, others to a much earlier period. Talls sags has been rendered famous, chiefly from being selected by the poet Tenfer as the subject of a beautiful poem of the same name, which has been repeatedly translated into English.

Frog. frog (Sax. froge), (Euxa).—The frogs are chiefly distinguished from the toxas by the unusual

has been repeatedly translated into English.

Face, Fee, (Sar. Feeg.), (Eura).—The frogs are, chiefly distinguished from the toads by the unusual length of the hind feet, which are strong and well-palmated; hence, their great power both of jumping and of swimming; their aim also is smooth; and there is not only a row of fine teeth round the upper jaw, but the palate also is furnished with another row placed transversely. It is one of the many singularities of these animals, that while in the young or tadpole state, they are harpiverous, living only, according to Cuvier, upon aquatic plants, yet no somer do they effect their upon aquatic plants, yet no somer do they effect their upon squatte plants, yet no somer do they effect their metsmorphosis, than they become carnivorous, pursu-ing slugs, insects, &c., and consuming them alive or dead. The frog deposits its ova or spawn some time in March, in a clustered gelatinous mass. This lives for a month or five weeks, and at the end of that time, there issues from each little black globule a living tadpole. issues from each mass change the young frogs have an elongated body, a laterally-compressed tail, and external branchise; their small mouth is furnished with small hooks or teeth, for the separation of vegetable matter, and the laws lin, by which branchies; their small moth is furnished with small hooks or teeth, for the separation of vegetable matter, and they have a small tube on the lower lip, by which they attach themselves to aquatic plants, &c. The external branchise next disappear, and become covered with a membrane, being placed in a sort of sac under the throat; and the animal them breathes after the manner of the flahes. Furnished with eyes and mostris, the body of the animal is distended with the great extent of the digestive canal, and it has a large tall for swimming. Soon, however, the posterior limbs are gradually put forth near the origin of the tail, and are developed first; the anterior feet then begin to show themselves; the tall gradually becomes less and less, shortens, shrinks, and seems at last to be absorbed; the mouth videns, and loses its horny processes or jaws; the eyes are guarded by eyelids; the belly langtheses and diminshes in comparative size; the intestines become abort; the true lungs are developed, and the internal branchisms of obliberated; the circulation undergoes an entire change; and the antmal, hitherto entirely aquatic and herriverous, becomes carnivorous, and for the most part terrestried. In the freg the muscular system, especially the muscles of the abdominal structure of the muscular some analogy to the abdominal structure of the muscles of the thigh and leg; in the fregs and other annound harronisms, that the greatest singularity is manifested. These, whether testem conjunity or singly, present the greatest analogy with the muscular structure of the manneliers. But it is in the disposition of the muscles of the thigh some and the remedia, clongsted, conteal thigh, the knee extending itself in the same dark to the leg, formed by the helly of the gastroomorii muscles. It is impossible to watch the intrincial motions of a frog in fire water, as it is implied, by these muscles and its wealth feet, without teing struck by the complete resemblance in this portion of its firence muscles. and they have a small tube on the lower lip, by which

### Fronds

to human conformation, and the almost perfect identity of the movements of its lower extremities with those of a man making the same efforts in the same situation. By the said of these well-developed fiver limbs, and the gradigious nower of their muscular and bony levers, a free team raise itself in the air to twenty times its own leading the same raise little in the air to twenty times its own leading and traverse in a single bound a space nearly fifty times the length of its own body. There are several species of frees, and among the most peculiar may be mentioned the buil-free of North America (Hana rejeises) and the tree-free (Hyla leverage traves). The former is a very large apecies, measuring sight inches in laught and four in width. Its colour is olive as the upper part, and greenish-white darket specings only, and, although it is a great destroyer of young goalings, it is interested from the beautits derived from its accordance from the beautits derived from its accordance. Each of the peculiarity is its vices, which resembles the distant bellowing of a buil. Of the tree-free there are several species. They are found in France, Germany, and itsly, as well as in America and asia. Eays fir filmerson Tennent, "In the shrubberies around my house at Colombo, these graceful little frees were to be found in great numbers, crouching under broad leaves, to protect them from the scording sun. Some of them utter a sharp metallic sound af night, like that produced by smacking the lips. They possess in a high degree the power of changing their colour; and one which had seated himself on the gilt pillar of a dimer-lamp was scarcely to be distinguished from the ormain to which it clung. They are enabled to ascend glase by means of the suckers at the extremity of their toes. Their food consists of flies and minute coloepters." Although this latter species live in trees, they lay their means of the suckers at the entremity of their toes. Their food consists of flies and minute coleopters. Their food consists of flies and minute coleopters. Although this latter species live in trees, they by their eggs in the water, and even hybernate in the mind during the winter. Africa also posduces a singular race of frogs, which, from having some of their toes enveloped by a conical horay diaw or cap, have been ermed Dactylethre, or thimble-toed—Ref. Broderin, Swainson, Tennent, Yarrell, English Cyclopedia.

articulated; they are either seesile or stalked; are frequently toothed or incissed in various ways, and are often highly compound.

FROWING, frond (Fr., a sling), in the history of France, is the name of a political faction which sprang up during the minority of Louis LLV,, and opposed themselves to the government of the prime minister, Cardinal Mazaria. The people opposed to the court party were called Frondeurs, or Consurers, on account of the censures which they passed against the government; and hence they acquired the name of the Fronde. The despoile policy of the prime minister had given offence to all clauses of the people; and at leugth the parliament rose in open opposition to him, and refused to pass or register his measures. In consequence of this, the cardinal ordered the arrest of the president and one of the councillors on 26th August, 1646. The people of Paris immediately took up arms against the government, and the following day (to journée des berrieddes) batricaded the streets, and compelled the Mercation of the two prisoners. Peace was thus in some measure restored; but if was not of long continuance, for the prople still continued tunultuous, and in January, 1649, the queen regent removed with her son to St. Germain, charging the primes of Conde to blockade the city. Among the leaders in the popular cause, were the prince of Conde, the duices of Beaufour, Neuroura, Vandôme, Longueville, the Cardinal delete, Marabai Turanne, and many offsers of Hearing, and the removed army of August. In January, 1649, the queen and continued them to be arrested, by which proceeding the remain of August. In January, 1650, the queen offended by the conduct of the photes of Ocuade and Conti, coused them to be arrested, by which proceeding the remain of Ocuade and Conti, coused them to be arrested, by which proceeding the remains of Ocuade and Conti, coused them to be arrested of the soverment. Turanne was defeated at Residues for the soverment.

after; but at length, all parties being wearied with these dissensions, the court agreed to remove Mazarin, and a general amnesty was produced. Condé, who refused to be a party to these terms, new finding his cause desperate, entered the Spanish service; while Mazarin after a time returned to Paris, and again obtained the refuse of government.—Bef. Sist. Aulaire's Histoire de la France. 3 vols, Paris, 1827.

FRONKLI, Front'-di (Lat. Franc. 18 forchead), at the frontal bone, arteries, nerves, to. The frontal bone is that bone of the skull which goes to form the forehead; as well as part of the temples, the upper portion of the

as well as part of the temples, the upper portion of the nose and orbits, and part of the base of the stull. It is convex anteriorly and concave posteriorly, resem-bling somewhat in stape the half of a cockle-shell. On the inner surface there is a ridge, hardly perceptible at the upper part, but becoming more prominent towards the bottom, to which the falx cerebri is attached. The frontal sinus is a cavity, usually occurring between the two plates of the frontal bone behind the eyebrow, and

two plates of the mose.

FROWNIER, front-yeer (Ital frontiera), is the boundary of a state, or the lands immediately adjoining its boundary. It is of great importance to a country to have a strong frontier, so as to reader it little liable to any sudden attack, and to make it easy of defence. The best frontier is the sea, and the next best great moun-tains or rivers, as the Alps or Pyrenees, the Rhine or the Rhone. These are termed natural boundaries, as distinguished from artificial or conventional boundaries, or such as are determined merely by treaty. Prussi has the worst frontier of any European state, and would find it very difficult to protect itself in the event of a continental war.

FRONTISPINCE, front is pees (Lat. frons, front, inspicio, I look upon), a term need to denote the engraving or ornamented page which is placed in the beginning of a book. In Arch., frontispiece signifies the principal face or front of a building, and the decorated entrance to the same.

FEUT, frute (Fr. fruit, Ital. fruite), in Rot., that
part of the plant which is formed by the ripening of the
overy and its contents, after the process of fertilization. The fruit consists essentially of the mature overy. with its seeds or ripened ovules; but other parts of the flower may enter into its composition. Thus in case where the calve is adherent to the ovary, as in the apple, melon, and gooseberry, that organ necessarily forms part of the fruit; in the rose, the concave thala-mus, which bears the carpels on the inner surface, be-comes a portion of the fruit; in the strawberry, again, the fruit dozsists of a succulent hemispherical thalamus, the fruit donsists of a succulent hemispherical thalanus, bearing the carpels on its convex surface; in the acorn, hazel-nut, and filbert, it consists of pistil, calyx, and bracts, combined together; while in the pineapple, it is composed of the ovaries, floral envelopes, and bracts of several flowers. As the ovary ripens into the fruit, it frequently undergoes important alterations, from the addition or the obliteration of certain parts. Fruits formed by a single flower are divided by Professor Bentley into simple, amountages, and sengarous fruits. The fruit is simple, apocarpous, and syncarpous fruits. The fruit is simple when it is formed of a single earpel, and when it is the only one produced by the single flower. The legame and the drupe are examples. The specarpous fruits are formed of single carpels, but several are produced by a single flower. The follicle, achanium, and eterio are examples. Those fruits are syncarpous which are formed by the more or less complete combination of two or more carpels, and of which only one is produced by a single flower. The exceptions, asmark, capsule, heaperidium, berry, and pome, are examples. Fruits formed by the combination of several flowers, form a distinct class. They are sometimes flowers, form a distinct class. They are sometimes called anthocorpous fruits. The cone and symcoms are examples. Professor Beutley's classification is founded upon that of Dr. Lindley, but differs from it in some many countries at the present day, the principal fuel.

particulars. The fruit is described as superior or in ferior, in the same sense as when speaking of the overy. Thus a fruit is inferior when it is formed from an inferior ovary, in which case the only necessarily enters into its somposition, as in the apple and melon; it is superior when formed from a superior ovary, as in the poppy and pea; the only then being non-adherent. When perfectly formed, the fruit consists of two parts; When perfectly formed, the fruit consists of two parts; namely, the shell or pericery, and the inclosed seeds. In the majority of fruits, the pericary consists simply of the walls of the orary in a modified state; but where the calyx is adherent, it necessarily presents a more complicated structure. It is divided into three layers or regions,—the external, called spicary, or excoury; the middle, called mesocary, or sometimes, in allusion to its fleshy or succulent nature, the arrocory; and the inner, called the endocary, or, when very hard, the stone or pushumen. The pericery either opens to allow the seeds to escape, or it remains closed, and the seeds can only become free by its decay. In the former case, the fruit is said to be debiscent; in the latter, indebiscent. Debiscent fruits open in various weys. When a fruit separates more or less completely into two or more pieces, called values, or even when it opens by a more pieces, called values, or even when it opens by a single longitudinal slit, it affords an example of valueur deliscence. When the opening takes place by a transverse line through the fruit, so that the upper part is separated from the lower, like the lid of a pill-box, the deliscence is said to be transverse or circumscissile. A third kind of dehiscence, called porous, is distinguished. The seeds escape through little pores or slits, formed irregularly in the substance. irregularly in the substance of the fruits, by a process

called rupturing. (See Ovary, Sund.)
Frustum, frus'-tum (Lat. frustum, a morael or gobbet), in Geom. and Math., the name applied to any piece cut from any solid figure, but more particularly to the bottom of a cone or pyramid, from which the upper part, which contains the spex, has been cut

FUCESIA, fu'-che-d (SO BERREY IN BOLLING), a gen. a famous German botanist of the 16th century), a gen. FUCHSIA, fu'-she-d (so named in honour of Fuebs, of shrubs belonging to the nat. ord. Onagracea. species F. coccinea, a native of South America, was introduced into this country at the close of the last century, and is now one of our commonest greenhouse and window shrubs. It is a very elegant plant: the young wood and nerves of the leaves are tinged with purplish-red; the flowers are produced from the axis purpissis-red; the flowers are produced from the axis of the leaves, and baug in a most graceful manuer by thread-like pedunoles; the catyx is tubular, scarlet, and 4-lobed in the limb; the petals are equal in number to the divisions of the catyx, and of a rich purpis colour; the stamens are numerous, and, together with the style, form a pretty tassel. Many species have been introduced into Britain, besides R. coccioses, and an immense number of beautiful varieties have been developed by cultivation. The fruits of several fuchaias

loped by cultivation. The fruits of several fuchsias are somewhat acid, and may be eaten.

Fueve, fu'-kus (Gr. phukos, sea-wrack), in Bot, a gen of marine plants or Alga. Several species contain maunite; as F. vescoilosus, nodosus, serratus. The former, commonly known as the bea-wrack, is much used during the winter months in some of the islands of Scotland for feeding horses and cattle. The expressed juice of its vesicles has been used medicinally as an juice of its vesicles has been used medicinally as an internal remedy, and frictions of the plant have been employed externally in glandular and scrotulous affections. The substance called vegetable Ethiops, which was formerly much used in similar diseases, is a kind of obserced, produced by the incineration of this alga in close vessels. The beneficial effects of these remedies may be traced to the iodine contained in the close.

remedies may be traced to the iodine contained in the plant. The sea-wrack was formerly extensively employed for making help.

Furl, fw-el (Fr. fsv. fire), a term applied to certain substances used for the purpose of creating and maintaining heat; such as coal, coke, chevoel, wood, and a few other substances, which are burned in grates, stoves, fireplaces, furnaces, to. The combustion of fuel is used either as a source of heat or of light. The processes connected with the latter will be found under the article far Manuscruus. With regard to the use of fuel for the purposes of heat, wood must have constituted, in the early ages of the world, as it does in many countries at the present day, the principal fuel.

#### Fueros

Another kind of fuel, which must have been used in accient times, ignest, or turf, a natural accumulation of vegetable matter. In many parts of England, Wales, and Scotland, where coal is not readily procurable, peat is still much used. Small deposits of peat are found in almost every country, but districts of immense extent occur in Holland, North Germany, on the Rhine, the peat is cut by common spades into the shape of thick bricks, and then dried. In Holland, the preparation of peat for fuel closely resembles brickmaking. In this country, the principal supply of fuel is furnished by coal, and its various kinds are employed in different ways and for different purposes, according to its nature, and that of the substance to be acted on yits agency. By partial combustion, both wood and Another kind of fuel, which must have been used in by its agency. By partial combustion, both wood and coal can be freed from their more volatile constituents, namely, oxygen, hydrogen, and nitrogen, leaving the carben more or less isolated. Wood so prepared is called charcoal; and coal, by a similar process, is converted into coke. Charcoal and coke burn for a longer period in a given bulk, and do not occasion any smoke. In some countries the excrement of animals smoke. In some countries the excrement of animals is used for fuel; and the formation of sal-ammoniso was derived, in Egypt, from the burning of camel's dung, the chloride of ammonium subliming from the excrement while it was burning. In small chemical operations tallow or wax candles are often employed as fuel; and at the present time, in laboratories, coal gas is simost entirely used for the purposes of boiling or evaporating small quantities of fluids, &c. Within the last few years, artificial fuel has been much manufactured. There are many methods; but the greatest number consist of processes by which small or dust bituminous coal, anthracite, charcoal, or coke, is made up into square or rectagonal blocks, which can be easily stored away without loss of room. The substances used for binding the dust-coal together vary. Sometimes it is mixed with earthy substances, such as sand, marl, clay, or alluvial deposit; or with some bituminous substance, such as mineral tar, coal tar, gas tar, pitch, resin, or usphalt; or with sawdust, coke-dust, or breese. A useful patent fuel is made by compressing peat so as to form a dense brown combustible solid and uselies the house said of the same said. tible solid, not unlike the brown coal of Germany. Some valuable information respecting fuel has been published of late years, in the government reports on the coals suited for the royal navy. The chief test of the value of any particular coal has always, in these investigations, been its avaporative power, or its power of converting water into steam. The best qualities of coal fuel for ships of war have been stated to be as follows :- 1. The fuel should burn with a quick action, so that steam may be raised in a short period .- 2. It should possess high evaporative power; that is, be capable of converting much water into steam with a small consumption of coal.—3. It should not be bituminous, lest so much smoke be generated as to betray the position of ships of war when it is desirable that the position of ships of war when it is desirable that this should be concealed.—4. It should possess considerable cohesion of its particles, so that it may not be broken into too small fragments by the constant attrion which it may experience in the vessel.—5. It should combine considerable density with such mechanical structure, that it may be easily atowed away in small space; a condition which, in coals of equal evaporative values, often involves a difference of enore than 20 per cent.—6. It should be free from any considerable quantity of sulphur, and should not progressively decay; otherwise, in either case, it is liable to spontaneous combustion. to spontaneous combustion.

Fugues, fa-ci-ros, is a Spanish term, derived from the Lat. forum, which signifies a place where justice is administered; and hence, jurisdiction. From this latter

# Fugitive-Slave Law

Basque provinces of Biscays, Alava, and Guipuzcos. It is in this last sense that the word is now almost exclusively used, the fueros of the other provinces and towns of flpain having long since become extinct. The subject has, in recent times, acquired a fresh importance, from having given rise to the revolution of 1833, in the Basque provinces, which led to a series of sanguinary conflicts, and which was only terminated by the queen and government, in 1844, entering into a formal recognition of the success these givens are based upon the of these provinces. These rights are based upon the sacient laws of the Visigoths, and were developed in the period between the fall of the Moors in the Spanish pennsula and the complete consolidation of the Spanish mouserby under the house of Hapsburg. The fueros thus owed their rise to the old Gothic laws, and se they took their form from the struggles between the people and their princes, they differ considerably in the different provinces. In 1236, in consequence of the contests carried on between the king Theobald and his cortes, the fueros of the kingdom of Navarre were collected and written down; and still exist under the name of "Cartulario del Rey Tibaldo." In Biscava, the fueros arose chiefly in the contests between the inhabitants of the counties and their counts. inhabitants of the counties and their counts. They were collected together in a book in 1971, by Count Juan, which was enlarged and improved by Corregidor Mora in 1452. After Biscaya became united with Castile, its fueros were, in 1526, revised and confirmed by Charles I. of Spain, who was also Charles V. of Germany. In the province of Alava, which went over from the government of Navarre to that of Castile, in 1200, the fuero of Logrono formed the basis of their purillarse, which were still crythay actorized in the spherosciples. privileges, which were still further extended in the sub-sequent contests of the Alayses with their Castilian lords, and were confirmed by the constitution of John II. of Castile. The province of Guipuzcoa received its II. of Castile. The province of Guipuzcoa received itsfueroe from the kings of Navarre, and they were subsequently confirmed by the kings of Castile, when that
province came under their dominion. The fueros were
thus received at different times, and in different forms,
in the several provinces; and hence they differ considerably, as regards their details, in the several provinces; but the main features are the same in all; the
form of government being essentially republican, and
the royal authority little more than nominal. In
Biscays, for example, the king has only the power of
nominating the corregidor, or chief magistrate; and nominating the corregidor, or chief magistrate; and ven his nomination requires to be confirmed by the junts of the province, a legislative body elected by almost universal suffrage, and intrusted with the chief management of public affairs. The inhabitants are exempt from all taxes and imposts, except such as they exempt from all taxes and amposts, except such as they vote themselves; and claim, by virtue of pure Biscayan descent, the privileges of Spanish nobility. They are not obliged to appear before any tribunal beyond the bounds of their own territory, or to allow any royal monopoly, or admit royal troops within their territory, or to furnish recruits for the royal army.

FUGITIVE, fu'-jit-iv (Lat. fuga, flight), is a person obliged to fly from his country, or remove from a place obliged to fly from his country, or remove from a place where he had some abode or establishment, on account of his crimes, debts, or other circumstances. In the Roman law, a fugitive slave was one that was given to fles or run away from his master; and in selling a slave, the master was obliged to declare whether or not he was fugitive.

FUGITIMS PLAYE LAW.—According to the constitution of the United States of America, Gaussian carif

tion of the United States of America, slaves, or, as it is mildly put, "persons held to service or labour in one state, under the laws thereof," fleeing or escaping into another state, shall be delivered up, on claim of the party to whom such service or labour may be due. The previous exactments on this subject have been administered; and hence, jurisdiction. From this latter The previous enactments on this subject have been sense it came, in Spain, to be transferred to collections amended, and to a considerable extent superseded, by of laws; thus the Spanish edition of the ancient "Lex Visigothorum" was called the "Fuero juzgo." From imposed by this act are to be performed by any United hence it came to be applied specially to the rights one. States commissioners who may have the power of imferred by the crown on particular cities, the most states commissioners who may have the power of imferred by the crown on particular cities, the most states commissioners as the respective concessions, pivileges, the word fuery came to be specially used in this sense, and to denote, in particular, the entire body of immunities and privileges which lar, the entire body of immunities and privileges which composed the constitutions of Navarre, and the three

#### Fugue

warrant and arrest from the officer having due authority, when the fugitive must be taken before a comrity, when the legitive-want be taken before a com-missioner or judge, whose duty it is to hear and deter-mine the complaint in a summary manner; and, upon satisfactory proof as to the identity of the fugitive that he is escaped and owes service to the claimant, it is the duty of such judge or commissioner to deliver to the claimant a certificate of the proceeding had, with authority to remove the fugitive to the place from which he had fled. The testimony of the fugitive is not admissible. Any assistance rendered to a furifive which he had belt. The destinanty of the lightly a not admissible. Any assistance rendered to a fugitive to enable him to escape from the claimant, or any obstruction offered to his arrest, is made penal, and also subjects the party to damages at the suit of the owner. All citizens are required, when called upon, to render the officers personal assistance when they may be resisted in the configuration. sisted in the performance of their duties. Such was the law on this subject previous to the commencement of the present unhappy struggle; but what the future enactments may be, still remains to be seen.—Ref. Kent's Commentaries on American Law. Boston, 1858.

Boston, 1858.

Fugue, fuge (Fr.), a term signifying a composition, vocal or instrumental, or both, in which a determined succession of notes, called the subject, passes successively, and alternately, from one part to the other, according to certain rules of harmony and modulation. There are four kinds of fugue; vis., the "strict fugue," in which the subject is given out by one part and answered by another, the subject being again repeated in the third part; the "free fugue," in which the composer is not so much restrained, but is repeated in the third part; the "free fugue," in which the composer is not so much restrained, but is allowed to introduce passages not closely related to the theme; the "double fugue," in which there are two subjects occasionally intermingled, and moving together; and the "inverted fugue," in which, as its name implies, the theme is inverted.—Ref. Dr. Crotch's Relements of Composition; Clementi's Practical Harmony; and the English Cyclopadia.

Fulcaux, full-krum (Lat.), the prop, or other support, by which a lever is sustained, or the fixed point about which a lever moves. (See Level)

Fulcaux, full-gol-ri (Lat. fulgor, an effulgence), a gen, of hemipterous insects, popularly known as lanternies, from their power of diffusing light in the dark. The American lantern-fly may be taken as the type of this family. The form of this insect is very remarkable. The head is dilated in front, with porrected protesters and the contractions of the samily.

or this family. The form of this insect is very remarkable. The head is dilated in front, with porrected protuberances; and it is from the hollow or lantern of the head that the light is said to proceed, and from no other part. "Two or three of these insects put into a glass vessel afford light sufficient to read by, without difficulty, if they be placed close to the bed. Even when the insects are dead, their bodies will afford considerable light, though less vivid than before; and if bruised and rubbed over the hands and face, they become luminous in the dark, like a beard smeared with English phosphorus."—(Nat. Hist. Guinea, Bancroft.) Madame Merrian, in her work on the insects of Surinam, was the first to draw attention to this insect. "The Indians," says she, "once brought me, before I knew that they shone by night, a number of the lanternies, which I shat up in a large wooden box. In the night they made such a noise, that I awoke in a fright, and ordered a light to be brought. We soon found that the noise came from the box, and opened it, but were much slarmed, and instantly let it fall to the ground with affright, on perceiving flames of fire issue from it; for as many animals came out, so many flames appeared. When we found this to be the cause, we recovered from our terror, and again collected the insects, much admiring their splendid appearance."

FULER'S EARTH, fall-lers erth, in Min., a porous soft silicate of alumina, having a strong attraction Madame Merrian, in her work on the insects of Surinam,

soft silicate of alumina, having a strong attraction for greasy matters. If made into a paste with water, and hid upon a greasy spot, it removes the fatty or oily matter by capillary attraction. It is found abun-dantly at Reignte, in Surrey. It is largely used to cleanse woollen fabrics from the grease contained in

cleanse woollen labries from the grease contained in the wool from which they are made.

FULTIMATING GOLD, full-min-at-ling (Lat. fulmen, a thunderbolt), in Chem., a fulminating compound of gold, made by digesting teroxide of gold in solution of ammonia, the formula of which is said to be Au<sub>8</sub>O2NH<sub>3</sub>HO. A similar fulminating compound is obtained by substitute of the said of

## Fumariaces

tuting terchloride of gold for the teroxide. A fulminating compound of platinum is obtained in the same manner by digesting sulphate of binoxide of platinum with ammonia. If simply precipitated oxide of silver, while still moist, is placed in contact with ammonia for any hours, a great part is discoved and a black or while still moist, is placed in contact with ammonia for some hours, a great part is dissolved, and a black compound remains, possessing powerful fulminating properties. It is regarded by chemists as a nitride of silver, Ag. N. These compounds all require investigating; but on account of their dangerous properties, they have been somewhat avoided by chemists. They must not be confounded with the fulminators, which are compounds of the metals with a true acid.

pounds of the metals with a true acid.

FULMINATING MERCURY, in Chem.—This compound, which is largely employed in the manufacture of percussion-caps, is made by dissolving one part of moreury in twelve of nitrio acid, apeo, grav. 0.35, to which are added eleven parts of alcohol, spec. grav. 0.850. On applying a gentle heat, by means of a water-bath, a violent reaction takes place, during which metallic mercury is separated, and in a short time grains of the fulminate also appear, which, when cold, are carefully washed with water. The composition for filling percussion-caps consists of six parts of nitre and one of the mercurial sult, made into a thin pasts with water. When curial salt, made into a thin paste with water. When wet it is harmless, but requires great precaution in

wet it is narmiess, but a value in the handling when dry.

FULMINATING SILVER, in Chem.—There are two compounds of silver known by the name, both of which are explosive by simple friction. The first, which is considered by some chemists to be nitride of silver, is considered by some chemists to be nitride of silver, in annuonis, considered by some chemists to be intride of sirer, is prepared by dissolving protoxide of silver in animonis, and adding solution of potash or soda; a black micaceous deposit falls, which is allowed to dry in minute quantities, on separate morsels of filtering-paper. The second is fulminate of silver, and is formed when nitrous acid is transmitted through saturated solution of nitrate of silver.

FULMINATION, full-min-ail-shun (Lat. fulmen, a thunderbolt), is employed in a general sense as synonymous with denunciation; but it is more particularly applied to the anathemas or excommunications burled

applied to the anothemas or excommunications hurled from the papal see against offenders.

FULMUNIC ACID, ful-min'-ik (Lat. fulmen, a thunderbolt, from the noise produced by the explosion of its compounds), in Chem., an acid possessing the same composition as cyanic and cyanuric acids, but having totally different properties. It is not known in an isolated state, but it forms compounds with the metals nossessed of nowerfully explaine properties. isolated state, but it forms compounds with the metais possessed of powerfully explosive properties. The best known of these, the fulminate of mercury, is used for priming percussion-caps. The fulminate of silver is also sometimes used as a detonating powder, but its use is attended with much greater danger than the corresponding salt of mercury. The latter is prepared by dissolving one part of mercury in twolve of mitric said to which elevan parts of slephal are added nitric acid, to which eleven parts of alcohol are added. On the application of a gentle heat, a violent reaction takes place, nitrous ether escaping, and fulminate of

takes place, nitrous ether escaping, and fulminate of mercury being gradually formed.

FUMAGE, fu'-māj (Lat., fumus, smoke), was the name of a tax formerly levied in England, and vulgarly known as smoke farthings. It is mentioned in Domesday Book, as being paid by custom to the king, for every chimney in the house; but it was first established by statute in England by Charles II. (13 & 14 Car. II. c. 10), when an hereditary revenue of 2s. for every hearth, in all houses paying to church and poor, was granted to the king for ever. It was, however, abolished upon the revolution, by 1 Will. & Mary, c. 10.

FUMARIAGEE, fumi-re-ni-se-e, in Bot., the Fumi-try fam., a nat. ord. of Dicotyledones, sub-class Thalamiflora, consisting of 15 genera and shout 110 species, principally occurring in thickets and wasto places in the temperate latitudes of the northern hemisphere. They are smooth herbs, with a watery juice, and alternate, exstipulate, much-divided leaves; flowers very irregular and unsymmetrical, purple,

flowers very irregular and unsymmetrical, purple, white, or yellow; sepals 2, deciduous; stamens hypo-gynous, usually 6, diadelphous, or 4 distinct, always opposite to the petals; ovary superior, with parietal placentas; ovules horizontal, amphitropal. The Funariaceæ possess slightly bitter, acrid, astringent, disphoretic, and aperient properties. Some species are cultivated in our gardens and greenhouses. Of these

## Fund, Sinking

the most important is Diosetro spectabilis, which has vary shown but seenther flowers. The order is named

the most important is Diosecto spectabile, which has very showy but seemines flowers. The order is named from Functio, one of the genera.

Furn Functio, one of the genera.

Furn Functio, one of the genera.

Furn Furnat., fon-di-ment-dif (last, fundows, the bottom of a thing), in Mus, is a term applicable to either a chord ar to a note; to the former, when its lowest component part is the nets the which the introduced in the second of the laster, when it is both the lowest compituent part of a chord and the note from which the harmony is really and nominally derived.

Furni, or Furning System. (See Marional Deri).

Furnat. (See Burlin.)

furnat be regulated by custom and the condition of the deceased. If the executor or administrator be extraorgant, it is a species of devastation or waste, and shall only be prejudicial to himself, and not to the creditors or legatees of the deceased. It seems that, according to the law of England, the widow has no claim for mournings, either against the executor or creditors of her hasband; but, in Seotland, mournings to the widow and those of the children who resided in family with the deceased are valid charges.

Furnal Cartons.—The sustom of delivering

family with the deceased are valid charges.

FUNDRAL GRATIONS.—The sustem of delivering funeral orations on the occasion of the death of any distinguished person is of very great antiquity. They were in use among the ancient Greeks and Romans and were very common among Christians in the early ages of the Church. The funeral orations (Gratons Funders) of Bossuet and Fischier are justly celebrated for their sloquence.

Funderes) of Boseuet and Flochier, are justly celebrated for their eloquence.

Furar, fin'ji (Lat.), in Bot., the Mushroom fam., a nat. ord. of dootyledones, sub-class Thallogene, consisting of parenchymatous cellular plants, growing in or upon damp mould; in or upon the wood and the herbaceous parts of living or dead plants; upon living or decaying animal substances, and in solutions of organic materials. A great number of species are microscopic plants. The vegetative structure of every fungus consists of a mass of exceedingly delicate, jointed and branched, colouriess, interlacing filaments, forming a kind of cottony or fetty mass when grewing in the ground. This vegetative structure, called the successium or spawn, nouriable a reproductive structure, which respectively include the mushrooms and their allies, the puff-balls, the smuta, the mildews, the truffles and morels, and the moulds. (See Agarious, Amantia, Lycoferdon, Cordina, Turner, Morghella, Princullivin).

Funcois, final grey (Lat.), in Surg., is a term applied to any luxuriant formation of flesh on an ulcer, commonly known as proad flesh. It is also applied to act and excreacential.

soft and excrescential.

soft and excrescential.

FUNGUS MINITANES, mc-ll-ten'-sis, the name used by the pharmacologists to designate a parasitic plent which formerly had a great reputation as a styptic. Its botanical name is Gymonorism concineme, and it belongs to the nat. ord. Bolemophoraces.

FUNGULUS, fundit-telus (Lat. funds, a cord or cable), in Bot., the stalk by which the svale or the seed is attached to the placents. When this stalk is absent, the seed is said to be seasile. (See OVUR. SEED.)

FUN, fur (Fr. fourture), the long, fine, silky hair of some wild animals, as the bear, wolf, marten, beaver, which is dressed and prepared as an article of dress. Fur being one of the principal non-conductors of heat, it is an especially warm covering, and those fure are Fur being one of the principal non-conductors of heat, it is an especially warm covering, and those fura are the best which belong to animals which inhabit cold climates. The furs which are imported may be classed in two different sections,—the falled fur and dressed fur. The first section comprises the furs of the hare, rabbit, beaver, and nutrie; and these are principally used for hatmaking. Dressed furs are principally used for intraking. Dressed furs are those which are preserved along with the felt to which they are attached, and are used for thatmaing of articles of dress, mulliers, rugs, mantles, and such-like. Furs are imported into this country from North America.

### Furnace

and Russia, and the trade is a very important one, as above 5,000,000 akins of fur-hearing animals are annually brought into Britain. The Russian sable is one, of the most expensive, some single skins fatching 59, although the average price is between £3 and £5. The Hudson's Bay Company was established in the yest 1870, by an especial charter from Charles II., for the purpose of carrying on this trade in North America, by means of kunters sent out for the purpose, and by tradic with the numerous wild tribes of Indians, which at that time populated nearly the greater part of America. Quebec and Montreal are the principal trading stations of the company. The operations by which furs are manufactured into a fit statefor the covering of hat, 5c, is retermed "intriery," and are carried on in the following manner. Feited fore, for hets, are first spread out so as to exhibit a fit surface, and the skin is combed with a kind of saw bermed a rake, so as to cleanse off any impurities without detaching any of the hair of far itself. The being achieved, the skin is then damped on the inner surface, and the six is then damped on the inner surface, and severalers preceds the advent and take out reads it than perfectly smooths and area and take out achieved, the skin is then damped on the inner surface, and severalere pressed together in the gross, so as to render them perfectly smooth and even, and take out any oreases or folds. The next process is to separate the furry cost from the felt underneath. The coating is of two kinds,—long lairs, which are not strictly fur, and a shorter cost underneath, which is the true fur required. These are separated by a long pair of shears, which first detaches the long rough hair. The real fur is then removed by a much more delicate operation. The skin is extended and stretched perfectly even upon a cutting-board made of willow, which is coassionally wested to avoid blunting the knife used in the process. This knife is extremely sharp—in fact, is occasionally wested to avoid bluning the kinic used in the process. This kinic is extremely sharp—in fact, as sharp as a razor, and is about six inobes long by three broad, and it can be used either backwards or forwards, being shaped somewhat like a cheese-cutter. With this instrument the fur is separated from the forwards, being shaped somewhat like a cheese-cutter. With this instrument the fur is separated from the skin, the operator working down from the head to the tail (the natural direction which the fur takes on the animal to which it belongs), and it is then carefully collected and sorted out according to the different degrees of excellence which it possesses. It is now it for the purpose for which it is intended. Dresed fury.—The operation for this species is much more simple than that of felted furs, as the hair or fur has not to be removed from the felt. Only two processes are mecessary,—that of cleaning the skin from all impurities, and extracting a species of oil from the fur itself. The skin is first steeped in a liquid composed of bran, alum, and salt; it is them worked about and soured sufficiently to remove all particles of grease which might still adhere to it. The fur is then washed several times with sods and fine soap, after which it is regularly cleaned in cold water repeakedly. The alum having rendered the skin soft and pliable, and the fur being fully prepared, the dressed fur can now be made up into the different garments and trimmings for which it is to be used. The use of furs seems to have been first introduced into Europe about the 6th century, about which spoch ashle skins were brought to Rome from the shores of the Arctic Ocean by northern inveders. They appear to whave been in regular use in Ragiand in the 14th century, as we learn to Rome from the shores of the Arctic Ocean by northern invaders. They appear to have been in regular use in England in the 14th century, as we learn that Edward III., in the year 1337, commanded that none of his subjects should wear them unless they had an income of £100 annually. The Hudson's Bay Company even still have the pre-eminence which they had some two centuries back, as their system is so was that they command nearly avery market. They hold annual they command nearly every market. They hold annual sales in London in the month of March, and many manes in account in the month of march, and many foreigners come over for the express purpose of pur-chasing fara, which are disseminated over Europe through the agency of the grand fair at Leipsic. It is asserted, in a capital article on the subject in the English Encyclopadia, that the value of furs used in Europe every veer cannot be much less than 27,000,000.

Baglish Encyclopadia, that the value of fur used in Rurope every year cannot be much less than 27,000,000. Furlows Darvine. (See Darvine, Furlows). Furlows, fur-long (Sar. furlows), an English mea-sure of length, which denotes the eighth part of a sails, or 250 yards. Furlows, fur-lo (Du. verlof); in Mil. language, the leave of absence granted to any officer or man to absent himself from duty for any length of time. Furlaces, fur-not (Let. furnar), an inclosed fire,

Frien, Area (Fr. fasil), a kind of Britock similar to the old market, but lighter and shorter. Some of

Fusiliers

the light infantry regiments in the British army were armed with this weapon prior to the introduction of the Enfeld rife, from which they acquired the fishinative appellation of fusiliers. Of these, the String Boyal Welsh Fusiliers, raised in 1888 or 1898, is perhaps the most distinguished. The 7th and first regiments were also raised adoptaths time, so the English and Scotch Fusiliers, when the fault was first introduced from France, having should been in use in shat occurry, for about half contary. One of the regiments of the foot-guards, or households troops, is also distinguished as the Stots Fusilier Fusical.

FUSILIESS. (See Fusil.)

FUSILIESS. (See Fusil.)

FUSILIESS. (See Fusil.)

FUSILIESS of the initial in manufacture to velvet, having, in addition to the warp and Well, a species of pile, consisting of other threads doubled together, which are throws up in ridges and conceal the original

of pite, consisting of other threads doubled together, which are thrown up in ridges and conceal the original warp sad weft, which are the groundwork of the fabric. When in the loom, this pile presents the appearance of a set of loops; but these are afterwards out in two and sheared down. The fustian, when polished and finished, presents an evenly ribbed surface on the exterior. The best gescriptions of this class of roads are those known as cotton-wavet and surrace on the exterior. The best gescriptions of this class of goods are those known as cotton-wivet and velveteen; but, besides these, there are moleskin, conducty, and several other kinds. (For further information on the subject see Willyland.)

FURTLAM, in Criticism, is applied to a forced, bombatic style of writing, abounding with metaphors or other rhetorical figures.

other rhetorical agures.

FUSTIO, fust-lik (Sp. fusts).—There are two kinds of fustic used in dysing,—old fustic, which is the good of the Morus tindorie, and young fustic, which is obtained from the Rhus Cotinus. They are both valuable for dysing woollens yellow, and for impacting to them green and olive bues when mixed with indigo. (See

green and olive bues when mixed with indigo. (Nee Macture and Rays.)

FUTURE DEET, in Law, is a debt payable at some future and fixed period. Such differ from contingent debts, in that the payment of them is fixed, whereas in the other case payment depends upon some contingency. In the case of the death or bankruptay of a debtor, future debts are allowed to rank on the estate, interest at the rate of five per cent. being deducted for the period that has to elapse before the debt becomes strictly payable. strictly payable,

G.

G is the seventh letter in our alphabet, as well as in the Latin and all the other alphabets derived from it; while in the Greek and Oriental alphabets it occupies the third place. It has two counds,—one hard, as in gay, go; the other soft, as in gam, giant. It is hard before the vowels a, o, u, and soft before a and a. It thus resembles, which has the double sound of k and it is the seventh of the seventh o thus resemples s, which has the noble sound of k and s. G is liable to many changes in different dislects or languages, as interchanging with \$\mathbb{R}\_i, \mathbb{y}\_i, \mathbb{y}\_i,

and Italians.

G Fair, the note O depressed half a tone; the fifth note introduced in modulating by fourths from the

Casling to the flexibility of the osiers or brushwood that are used in making the gabions, are driven into the ground at equal intervals round the circumference of a circle traced thereon, with a radius of eleven inches, that the outer diameter of the galion may not arged two fast when it is completed. The willow rods, or any either material that can be obtained which is suicable for the garpose, are then twisted between and about this station, such successive layer of rods being tigffly pressed against the one below it, until the nearest work has attained the requisite height. The gabion is then pulled up, the calves are not off about the satisfied and the requisite height. The gabion is then pulled up, the calves are cut off about threadings from the thatest work at either and and charpened. Before Sebattopol, where brushwood was source, the stakes were intervoven with hoop from instead of withes, and the gual way. Tyler's gabion is a sheet of galvanised from, should be set in inches hook the contracted in the small way. Tyler's gabion is a sheet of galvanised from, should be set inches long and 2 feet 9 inches broad, that is brought into a circular form and retained in that position by passing a strong cord or wire through eyes punched along either end of the metal elset. Gabions are used in making earthworks. They are placed on and and filled with earth taken from the ditch dug out in front of the rampert. They add considerably to the strength of the mound, by affording supports to the strength of the mound, by affording supports to the strength of the mound, and the strength of the mound, the form of a considerably to the order that is from the direct strength one line of gabions is placed on top of another, a row of fascines is generally placed between them.

Ganza, gail-bl (Welsh gavesl), in Arch., the name given to the upper part of the end-wall of a building, the sides of which meet in an angle and afford support to the ends of the rafters of the roof. The angle thus formed corresponds to the slope of

and finial, which generally assumed the form of a cross in churches and buildings designed for exclosiational purposes. In Elizabethan architecture, the outline of the gable was composed of curves and angles variously the gable was composed of curves and apples variously combined, that known as the orges gable being the most common. It was often richly ornamented with open stonework. The sloping sides, particularly in old Scotch, Dutch, and German buildings, were sometimes finished in the form of a saries of steps, which, in Scotland, were termed "cubic steps," In domestic Gothic architecture, the roof generally projects beyond the face of the gable-wall, and an ornamental burge-board is attached to the end of the rafters. The end of a hones serminating in a gable is indifferently called the gable or gable-end of the building, as in the title of one of Hawthorne's best tales, "The House of the Seven Gables."

Seven Gables.

one of Hawthorne's best tales, "The House of the Seven Gables."

Gan, ghd (Ang. Sar.), a sharp-pointed wedge, used in Cornwall for splitting rocks.

Gan-Fix. (See Bor-Fix.)

Ganting, gai-de-de (Lat. gades, a cod-fish), a fam. of fishes of the soft-finned order; as the Cod. They are easily known by the position of the ventral fins under the threat and the pointed character of those fins. The bodysislon, rathes compressed, and covered with small soft scales. The head is scaleless; eyes lateral; jaws and anterior part of the somer furnished with several ranges of unsqual testin; the gills large, 7-rayed, and opening laterally; a small beard the tip of the lower jaw. Most of the species have the dorsal fin contained in two or three bundles; they have also fins behind the vent, and a distinct caudal fin. The greater number of the species live in cold or temperate seas, and furnish the greater portion the fish obtained is England and Americs. Their productive powers are very great, and the numbers in which they satisf in some parts of the ocean is perfectly incolubable.

Gantag, or Essa, Language and Interactures, gail-like. The language and the language of the language and and the language of the language and and the language of the language and and the language and language of the language and and and Interactures, gail-like. or Salve of the controlled of modelstring by fourths from the note introduced in modelstring by fourths from the natural or distonic mode.

Garstan, go-fet' (probably from the Ger. gobe, a spile of the salve of the women furshing alloyed to any tax or impost left upon commodities, but which afterwards come to be specially applied to any tax or impost left upon commodities, but which afterwards come to be specially applied to a subject of the loss come to be specially applied to a subject work of the loss of the species have the dorsal fin routened in two or three bundles; and the creating the controlled in the controlled fine the continued in the controlled specially and the controlled in the controlled of the subject of the first obtained in the construction of section of the first obtained in the construction of sections. These has been determined to the controlled of sections of the first obtained in the construction of sections. Most of the species have the dorsal fin routened in two or three bundles; at the tip of the lower law. Most of the women furnished with several ranges of the sev

Gaelic

the Gwyddelian or Gaelic, and to which belong also the Irish and Mass, or that spoken in the Isle of Man. According to Dr. Prichard, the Celts are of Eastern origin, belonging to the great Indo-European family. They arrived before the Teutons from the regions on the Oxus, and from Madia, and penetrated through the Allophylic races along the southern shores of the Baltic Sea, at a time of which we have no historic data. At the time of the Roman invasion, Celtic was the language generally spoken in Western Europe. The dialogts of the Celtic still spoken, besides the three directly mentioned, are the Wesh, and the language of Brittany; while the Cornish, another dialect, though not now spoken, is preserved in books. The three dialects, the Irish, the Scotch Gaelic, and the Manx, approach each other so nearly as to form, in fact, but one language, the peculiarities which distinguish them from each other not being sufficiently broad or vital to constitute either of them a tilatinot language. The differences between the spoken language of the Scottish Highlanders and the Irish exist purity in the pronunciation, partly in the grammar, and partly in the idioms. In the vocabulary, also, there are also marked differences in the language, as spoken in different parts of the Highlands; and a native of Sutherland has some difficulty sin understanding one of the southern districts of Argyle. The Gaelia, which, from a variety of causes, has retained, in a considerable degree, its original purity, is copious, bold, and expressive. It derives no assistance from the languages either of Greece or Rome, from which it differs in its structure and formation. Having affixes and prefixes, it greatly resembles the Hebrew, particularly in the inflections of its nouns and verbs. In Ireland, too, the Gaelia spoken in the different parts varies, and an intimate connection subsisted between that wo countries. For nearly four centuries, from about the Highlands and the north of Ireland were, at an early period, inhabited by the same race or races, and an intimate connection subsisted between the two countries. For nearly four centuries, from about the middle of the 12th to nearly the middle of the 18th century, according to Mr. Skene, "there was not only a close political connection between the western Highlands and islands and Ireland; but the literary influence was equally close and strong; the Irish senachies and bards were heads of a school which included the west Highlands, and the Highland senachies were either of Irish descent, or, if of native origin, resorted to bardio Highlands, and the Highland sennacines were evicer or Irish descent, or, if of native origin, resorted to bardio schools in Ireland for instruction in the language and the accomplishments of their art." A powerful influence must thus have been exercised upon the language and literature of the Highlands, which must language and literature of the Highlands, which must have become by degrees more and more assimilated to that of Ireland. The written and cultivated language of the Highlands thus came to be identical with that of Ireland; but, according to Mr. Skene, we have no reason to conclude, on that account, that there was not a vernacular Gaelio which preserved many of the independent features of a native language, and existed among the people as a spoken dialect. The introduction, however, of the Reformation, in the 16th century, ever rise to a religious literature, which, commencing gave rise to a religious literature, which, commencing in the written, or Irish Gaelic, gradually approached nearer and nearer to the spoken dialect of the country, and, accompanied by the preaching of the clergy in the vernacular dialect, tended to preserve and stereotype the language spoken in the Highlands in its native form and idiom. The first printed book in Gaelic was a translation of the form of prayer issued by John Knox, and wrinted at Ediphurch, 1867. The second a translation of the form of prayer issued by John Maor, and printed at Edinburgh, 1867. The second was a translation of Calvin's Catechism, published in Scot of the Apostle to Galatia are mentioned in the along with an English edition, in 1831. In 1859, the second of these that the epistle was written. Shortly Presbyterian syned of Argyle took up the work of issuing translations into Gashic of the metrical Psalms and of the Scriptures. In 1890, the first Bible was upublished for the use of the Highlands. All these works were in the Irish orthography and Irish dislect, authority, by attacking his character and asserting that he was not divinely appointed. Paul, therefore, the Bible, with a short vocabulary. The first work in his epistles, proceeds to controvert these errors, published in Scotch Gaelic was Baxter's "Call to the Unconverted," translated by the Rev. Alexander Mac-

farlane, in 1750, who, in 1753, also published the Psalms in Scotch Gaelic. In 1767, the art translation of the New Testament was published in the Scotch dialect; and in 1763, a translation of the Old Testament was undertaken by the Society for Propagating Christian Knowledge in Scotland, and completed in 1787. In 1816, a committee of the best Gaelic scholars was appointed by the General Assembly of the Church of Scotland to effect an improved translation of the Scriptures, the whole being published in 1826. The earliest specimens of Scotlish Gaelic poetry are preserved in a collection made in the beginning of the 16th century, by Sir James Macgregor, vicar of Fortingall and dean of Lismore, and now preserved in the Advocates' Library in Kdinburgh. A selection from it has recently (1862) been published, with translations, by the Rev. Thomas M'Lauchlan, and an introduction by Mr. W. F. Skene. Some of the poems are in pure Irish, others in pure Scotch Gaelic; and others in a mixed dialect, in which the one or the other idiom predominates. The MS. is of no mean literary value, as throwing some light upon the much-controverted subject of Ossian's poems. "It contains no fewer than twenty-eight-Cosianic poems, extending to upwards of 2,500 lines; nine directly attributed to Ossian, two to Farris or Forghus Filidb, and one to Caolie McRonan, the three bards of the Feine; two to Allau McRuadri, and one to Gillecallum Mac an Olla, bards hitherto unknown; and eleven poems Ossianic in their style and subject, to which no author's name is athitherto unknown; and eleven poems Ossianic in their style and subject, to which no author's name is attached." At is thus clear, "that the characters introduced into Macpherson's poems were not invented, but where really the subjects of tradition in the Highlands, and that poems certainly existed which might be called Ossianic, is relating to the persons and events of that mythic age;" and "that Macpherson had used many such poems in his work; but by joining separated pieces together, and by adding a connecting narrative of his own, had woven them into longer poems, and into the so-called epics." The Dean's collection affords a fair specimen of the poetic literature in the Highlands of Scotland before the fall of the Lords of the Isles, and the introduction of the principles of the hitherto unknown; and eleven poems Ossianic in their Highlands of Scotland before the fall of the Lords of the Isles, and the introduction of the principles of the Reformation.—Ref. The Highlanders of Scotland; their History, Origin, and Antiquities, by W. F. Skene, 1837. Also Mr. Skene's Introduction to the Book of the Dean of Lismore, 1862.

GAPP, grif (Irish grf), a kind of boom, employed in small ships to extend the upper edges of those sails which are secured to the masts by hoops or lacings, and which are usually extended by a boom below; such, for instance, as the mainsails of sloops, brigs, and schooners.

schooners.

schooners.

Galactodenden, găl-ăk-to-den'-dron (Gr. gala, milk; dendron, a tree). (See Brosinum.)

Galactomater. (See Lactomater.)

flower), in Bot., the Snowdrop, a gen. of the nat. ord. Ameryllidacest. The species G. nivals is found grow-ing wild in our thickets, and is much cultivated in borders for the sake of its early and pretty blossoms. It is a bulbous plant; the flower is solitary, white, and drooping, the inner segments being greenish. It is singular that no varieties have been developed from this favourite plant by cultivation.

singular that no varieties have been developed from this favourite plant by cultivation.

Galarians, Sr. Paul's Rifering to the specific about the year all of the canonical epistles of the New Testament, written, as is generally supposed, about the year all of the substitution of the canonical epistles of the New Testament, written, as is generally supposed, about the year all of the substitution of the epistle itself has never been called in question, and is frequently ofted by the apostolic and other early fathers. Two journeys of the apostole to Calatia are mentioned in the Acts of the Apostole, and if was probably after the second of these that the epistle was written. Shortly after his departure, Judaizing teachers appear to have some among them, preaching "another gospel" than that of Christ, and to whom they were giving heed. These teachers also endeavored to subvert the apostic's authority, by stacking his character and asserting

### Galaxy

doclaring that "though we or an angel from heaven preach any other goodel unto you than that which we have preached unto you, let him be accursed." He then proceeds to point out the relationship of Judaiam to Christianity; that they are now no leuger under the law but under faith, being made the children of God through faith in Jesus Christ; and erhouts them to "stand fast, therefore, in the liberty wherewith Christ halh made us free," and not to be "entangled again with the yoke of bondage." He also exhorts them not to fulfil the lust of the flesh; but to be led of the spirit, the fruit of which is love, joy, peace, &c. The number of commenteries on this spiatle are very numerous; among which may be mentioned those of Lutter, Winer, Rickert, De Wette, Allord.

GALMAN, (See MILKY WAY.)

GALMANUM, gill-dinum (Lat.), a fetid gum-resin used in medicine, internally as an anti-spasmodic, and externally as a stimulant and discutiont application to indolent tumours and chronic swellings. It

tion to indolent tumours and chronic swellings. It tion to indolent tumours and chronic swenings. It is imported from India and the Levant, having probably been brought down the Persian Gulf, and is usually met with in masses of a brownish-yellow colour, more or less translucent and shining. Botaniste have, as yet, been unable to determine the plant yielding this resin. Species of at least four different general training and the property of the have been suggested as the source by different writers. Galbanum is officiual in our Pharmacoposias, and is supposed to be the same substance as the chellenah

cripture. Galburn, gill-hu-lus (Lat., the nut of the coppressive), in Bot., a kind of fruit generally regarded as a modification of the cone. It is described and figured

under the head of CONE.

GALENA, gil-le'nii (Gr. galene, tranquillity, on account of its supposed effect in mitigating disease), an important mucral, forming the principal ore of lead. It is a protosulphide of the metal, and is found crystallized more or less distinctly in cubes of a deep leaden colour and strong metallic lustre. It is found in veius in crystalline rocks, and most abundantly in carbo-

in crystaline roces, and most sunnanny in carso-niferous limestone.

CALENIETS, gai'-les-ists, in Eccl. Hist., was the name of a religious sect, a branch of Waterlandians, Mennonites, or Anabaptists, which arose in the 17th century. Their founder was Galen Abraham Haan, pastor of a Mennonite congregation in Amsterdam, a nan of great penetration and eloquence, who was dis-ceed to law much proper stream two required the posed to lay much more stress upon practice than faith, and held that all who acknowledged the divine origin of the Old and New Testament, and led holy and virtuous lives, ought to be received into their communion.

GALERISIS, in Med. Hist., was a term applied to those who adhered to the system of Galen, more particularly as opposed to the Chemical school. The former ran much upon multiplying herbs and roots in the same composition, which they usually prescribed in the form of tinctures or attracts; while the latter dealt chiefly with mifteral substances, and professed, by means of various chemical processes or out of operations, to extract the virtues or essences out of them into a very small compact.

them into a very small compaes.

GALBRYERS, gittle-ri-deex (Lat. galea, a belimet), in Geol., a gen. of fossil sea-urchins, abounding in the Chaik formation, and from their shape popularly known in Kent and Sussex as "sugar-loaves." The shell is high, more or less conical, and oblong-oval at the base, narrowing towards the hinder part. These heliast-shaped echini can be found in the chalk clifts near Margate with little trouble.

GALTAGER. coll-coll-see. (from galium), in Bot. the

near Margate with little trouble.

Gallace, gill-e-ui'-se-e (from gallum), in Bot., the
Madder fam., a nat. ord. of Dicotyledones, sub-class
Corollifones, consisting of 10 genera and 320 species;
common weeds in the northern parts of the northern
termisphere, and also is the high mountainous districts
of Peru, Chill, and Australia. The order has the foltowing characters — Herbaceous plants, with whorled
extitudiate leaves and angular stems. Calyx apperior,
with the limb 4—3-lobed or obsolete; corolla monoretalous de Alebed members, stammers, eminetalous

albumen horny. The Galiaces are chiefly remarkable for the presence of a colouring matter in their roots. (See Rubla.) Some have valuable medicinal properties. (See Galium.)
Galipea, gd-le-pe-d, in Bot., a gen. of the rat. ord. Rutaces. The species G. officiadis and aspects vield the drug known as Angustura or Cusparia bark. They are natives of South America. (See Angustura BARK.)

SARK.)

GALIUM, gill-e-um (Gr. gala, milk, the flowers of one variety being used for curdling milk), in Bot., the typical gen. of the nat. ord. Galiacca. The species G. Aparius is the common goose-grass or cleavers. The inspissated juice or extract of this plant has been used with success in legra and some other cutaneous discass. The extracts of G. rigidum and G. Mollugo have been employed in exilence.

discasses. The extracts of G. regulum and U. Motungo have been employed in epilepsy.

Gallanter, gill-länders (Fr. galanteris), denotes bravery, heroism, intrepidity, notleness, as well as civility, or polite attention to ladies. It is easy to see how, in carlier times, when chivalry fostered alike valour and devotion to the fair sex, this word should have come to receive its double meaning. When the respect for ladies which chivalry cultivated decompanied more and more into frivious attentions. degenerated more and more into frivolous attentions, the word gallantry came also to be used in a less favourable sense; and at length it has come to receive a bad signification, as synonymous with lewdness or debauchers, though always recaining the meaning of bravery.

bravery.

Gall.-Bladder, gowl (Sax. gealla, gall; Lut. vesicula felliu), in Auat., is an oblong membranous receptacle, situated on the concare side of the liver, under the right lobe. It is about the size of a small heu's egg, and resembles a pear in shape. It has three coats,—an external or peritoneal, a middle or fibrous, and an internal or villous. The inner coat has a reticulated honeycomb appearance, but does not possess any follicles for the purpose of secretion. It serves as a reservoir for the bile, which, when digestion is not going on. regungitates through the cystic duct, serves as a reservoir for the bile, which, when digestion is not going on, regurgitates through the cystic duct, and is retained for future use. The cystic duct connects the gall-bladder with the hepatic duct, which proceeds from the liver, and the two, when united, form the ductus communis choledochus, by which the bile is conveyed to the ducdenum. The cystic duct presents internally a number of folds, which are generally an experiment of the cystic duct presents internally a number of folds, which are generally. rally circular.

CALLEON, gill-le-on, a name given by the Spaniards to a very large kind of vessel, with three masts and three or four decks such as those used by them in their commerce with South America, to transport the precious metals. In the Armada which was fitted out by the above nation in 1588 for the invasion of Engby the above nation in 1688 for the invasion of England, there were about sixty galleons. These were large, dumsy, round-sterned vessels, having bulwarks three or four feet thick, all of which were so encumbered with too hamper, and so overweighted in proportion to their draught of water, that they could bear very little carvas, even with smooth seas and light winds.—Ref. John Lothrop Motley's History of the United Netherlands.

GALLERY, gall-le-re (Dan. gallerie, Fr. galerie), in Arch., a passage open or closed on one cide, and having on the other side the doors of a series of apartments on the other side the doors of a series of apartments which open into it. In this sense it is synonymous with the term "corridor." In ecclesiastical architecture, the name is given to a floor midway between the ground-floor of the building and the roof projecting from the walls on either side, or at the west end, and supported on series of columns; or, if the span be short, a beam stretching from wall to well. They are used to obtain additional accommodation, but they are a reset disfluencement to obtain additional accommodation, but they are used to obtain accurate accommonation, but they are a great disfigurement to churches, especially when they are erected along the borth and south sides. The gallery at the west end of a church is usually set apart for the organ and choir. In theatres, the gallery is the range of seats above the upper boxes: it affords existipulate leaves and angular stems. Calyx superior, the worst view of the stage, on account of the great with the limb 4—0-lobed or obsolute; porella mono, equal in number to the lobes of corolla, and alternate equal in number to the lobes of corolla, and alternate with them; over inferior, 2-celled, with one solities of paintings, soulpture, and other works of art; and tary croot ovule in each cell; styles two; fruit 2-in Mar., to the balcony, that is generally made outside celled, indehiscent, with one exect seed in each cell; the stern of men-of-war and vessels of large size.

GALLEY, gill-le (Sp. galera), a low, flat-built vessel, much used in the Mediterranean See hefore

Galler, gall-le (Sp. galera), a low, flat-built vessel, much used in the Mediterranean Sea before the introduction of steamboats. They were long and narrow, fitted with two masts and lateen sails; and being propelled by ears as well as by sails, they were of great use in those long calms so frequent in the above-mentioned sea. The largest of the common galleys were about 166 feet long, 32 wide, and contained 52 cars. In the Spanish Armada, in 1588, four vessels, called galeases, were smployed, which were about one-third larger than the ordinary galleys, and were each of them rowed by 300 galley-slaves. "They consisted," says Motley, in his "History of the United Netherlands," of an enormous towering fortress at the tarro, a castellated structure almost equally massive in front, with seats for the rowers amidships. At stem and stern, and between each of the slaves' benches, were heavy cannon. They were gorgeously decorated. There were spiendid state apartments, cabins, chapels, and pulpits in each; and they were amply provided with awnings, cushions, streamers, standards, gilded saints, and bands of music. To take part in an ostentatious pageant nothing could be better devised; to fulfil the great objects of a war-vessel, to sail and to fight, they were the-worst machines ever launched upon the ocean."

Gallio Acin, gall-lik (from galls).—This important vegetable acid exists ready formed in the gall-nut, in

upon the ocean."

Gallio Acid, gall-lik (from galls).—This important vegetable acid exists ready formed in the gall-nut, in sumach, in valonia, and in a large number of other astringent vegetables. It is readily obtained by allowing an infusion of gall-nuts, or powdered gall-nuts firely moistened with water, to stand in a warm place for some weeks. A species of fermentation is set up, during which the gallic acid is formed in large quantities by the decomposition of the gallotanic acid or during which the gallio asid is formed in large quantities by the decomposition of the gallotannic acid or tannin contained in the galls. Gallio acid crystallizes in silky needles or brilliant rhomboidal prisms, which dissolve in 100 parts of sold water and three parts of boiling water. It is freely soluble in alcohol, but sparingly so in ether. Gallio acid is tribasic, according to Streeker, and forms three classes of salts, containing one, two, and three equivalents of metal. The gallates of the alkalies speedily absorb oxygen if exposed to the most characteristic reaction of this acid is the formation of a deen phinish black solution, when added to a most one activistic reaction of time and is the forma-tion of a deep bluish-black solution, when added to a mixture of the protosalts and persalts of iron. The gallates give no precipitate with gelatine, in which they are distinguished from the gallotannates. Heated to a temperature of from 410° to 420°, gallic acid sublines, and is whill converted into precognilic and carbonic temperature of from 410° to 420°, gallic acid sublimes, and is wholly converted into pyrogallic and carbonic soids. If the temperature passes 480°, melagallic acid is formed. Callic acid is extensively used as a source of pyrogallic acid, so largely employed in photographs. Gallican Causer, gdl-to-kån (from Lat. Gallia, Gaul), is the name given to the Roman Catholic church in France, which, although in communion with the see at Rome, maintains, in some respects, an independent position. It has, from the earliest times.

the see at Rome, maintains, in some respects, an independent position. It has, from the earliest times, enjoyed certain liberties and immunities, not as grants from the popes, but as forming part of her original constitution, which she has always striven to maintain. When the Church of Rome was grasping after temporal power, their efforts in France were frequently opposed by the sovereigns, and more than one conflict was the consequence. There thus arose two parties in the French church,—those who were opposed to the encroachments of the see of Rome, and were known as the Gallican party, while the supporters of the encroachments of the see of Rome, and were known as the Gallican party, while the supporters of the Boman see were known as the Roman, Papal, or Ultramontane party. The earliest important manifestation of this opposition appears in the pragmatic sanction of Louis IX., issued in 1268, which made the paying of taxes to the pope dependent on the consent of the king and the national clergy, and forbade the interference of a foreign power in the affairs of the national church. The spirit of independence was attemptional church. or me measure character. The spiric of independence was strengthened by the decrees of the councils of Constance and Basel, which were adopted by France at the assembly of estates as Bourges in 1438, and promulgated in the pragmatic sanction of Charles VII.,

the fundamental law of the Gallican church. the uncamental law of the Galliesn church. This placed the general council above the pepe, forbede the psying of taxes to the pope for appointing bishops and prelates, and abolished the annates after the death of the then living pope. This sanction was repealed by Louis XI. in 1461, but restored by Charles VIII., and by Louis XII. through the edict of 1496. It was superseded, however, by the concordat entered into by Francis I. with Leo X., who had promised to confer upon the king greater power in ecclesiastical matters Louis XI. in 1461, but restored by Charles VIII., and by Louis XII. through the edict of 1486. It was superseded, however, by the concordat entered into by Francis I. with Leo X., who had promised to confer upon the king greater power in ecclesisatical matters than he had hitherto enjoyed. This paction gave great disastisfaction both to the French people and the French clergy. In the reign of Louis XIV., a contest arose between that monarch and Pope Innocent XI. regarding the ecclesiastical, rights of the crown, which led to the drawing up of the well-known declaration of the French clergy in 1682, which has since been regarded as the charter of Gallicanism. It was drawn up by Bossuet by order of Leuis XIV., and contained the four following articles:—(1) Kings and princes are in temporal matters subject to no spiritual power, and the latter can never absolve subjects from their oath of obedience; (2) the pope is subject to the decisions of an ecomemical council; (3) the power of the pope is further limited, as far as France is concerned, by the established prescriptions and usages of the Gallican church; and (4) in matters of faith, size, the decisions of the pope are not infallible when not confirmed by the consent of the whole Church. These articles remained valid, and formed the palladium of the Gallican party in the Church that he revolution of 1789, when the Church was formally abolished. Napoleon, as first consul, again established the Church by a concerdat, which he concluded with Pope Pinss VII. in 1801. The following year he added certain articles to the concordat, to the effect that the proclamation of papal decrees depends upon the discretion of the government; that there shall slaways be an opportunity for an appeal to the concided a new concordat with Pins VIII. by which that of 1801 was should by the four propositions of the Bourbon dynasty established the Gallican church in a state of greater dependence upon Rome than it had been before; and in 1817 Louis XVIII. concided a new concordat with Pins party has become almost extinct. As an instance of the spirit that prevails, the Roman liturgy has been introduced into one diocese after another, until it has entirely superseded the old national liturgies. Under Napoleon III., the bishops claim the right to meet without previous authority in provincial councils, and the government, without deciding the legal question, has permitted them to do so, in order to avoid a conflict. Indeed, recent events in that country show that there is nothing the State is more anxious to avoid than a conflict with the Church. The Gallican church has produced some men of distinguished eminence and

### Galliciam

piety; among whom may be mentioned Bossuet, Féndion, and Pascai.—Ref. J. de Maistre, De l'Eglise gallicans; Dupin, Les Labertés de l'Eglise gallicans; and Fraysinous, Les vrais Principes de l'Eglise galli-

GALLIGIER, gdl'-le-sism (Lat., from Gallia, France), in Lit., is applied to any phrase or mode of speech used in our language, but which is modelled after the

French.

Galleracesova Biens, gallis-av-sis-us (Lat. galles, a cock), the name applied to such birds as, in common with the domestic cock, have the upper mandible vaulted, the nostrils pierced in a large membranous space at the base of the beak, and covered by a cartilaginous scale; wings short, flight laborious, and carriage heavy. Birds of this order have an extremely powerful gizzard, and generally a large globular crop; nest artices, and placed on the ground; eggs numerous; food pointed out to their young by the parent. parent.

GALLIOT, gill-le-ot (Fr. galiote), a kind of vessel used on the Mediterranean Sea, which is amaller than a galley, but larger than a felucea. The term is also applied to a strongly-built flat-bottomed vessel used as a bomb-ship. The Dutch, also, have a kind of strong, but heavily- and olumsily-built, merchant-ship, rounded both fore and aft, and of about 200 or 800 tons burthen, which they call by this name.

GALLON, gill-lon (Sp. galon), a measure of capacity, both for dry and liquid articles, which contains exactly four quarts. It is enforced by act of parliament, 5 Geo. IV. c. 74, that "the imperial gallon shall be the standard measure of capacity, and shall contain 10 lbs. avoirdupois weight of distilled water (weighed in air at the temperature of 62° of Fahrenheit's thermometer, the barometer being at 30 inches), or 277-274 cubic inches; and all other measures of capacity to be void. the barometer being at 30 inches), or 277-274 cubic inches; and all other measures of capacity to be void, as well for wine, beer, ale, spirits, and all sorts of liquids, as for dry goods not measured by heaped measure, shall be derived, computed, and ascertained from such gallon; and all measures shall be taken in parts, multiples, or certain proportions of the said imperial standard gallon. The old English gallon, wine measure, contained 231 oubic inches; and the old English gallon all measure, contained 282 oubic inches. As the imperial gallon contains 277-274 oubic inches, it follows that it exceeds the former wine gallon by about one-third; while it is about one-sixtieth less in capacity than the old ale gallon.—Eqf. Macculloch's Commercial Dictionary.

city than the old are gauon.—my. sacronactic cial Dictionary.

Galls, gawls (Sax. gealla, a gall), excrescences produced on the branches and leaves of trees by the attacks of insects. Oak-trees are especially liable to be thus attacked. Galls are extensively employed in tanning, for making ink, and for other purposes in the arts. The different kinds are described under the arts. The differences.

best quality is prepared by immersing the clear metal in a bath of moltan sine covered with as amall quantity of in by voltaic action, before being dipped into the sine; hence the somewhat absurd name by which it is commercially known. (See Leon, Galvanies.)

Galvanometer, galvan-om'es-ter (from galvanies.)

Galvanometer, a measure), an apparatus or instrument constructed for the purpose of detecting the presence of feeble electro-chemical currents. Instruments of this sort wore first introduced by M. Schweig.

presence of this sort were first introduced by M. Solweig-nents of this sort were first introduced by M. Solweig-ger, a German philosopher. The principle upon which his galvanometer-muliplier was made, depended upon the action which a voltaic current exercises upon a magnetized needle. A conductor traversed by a current placed above a needle, but very near it, and parallel to its axis, makes this needle turn to the east

## Gambling

current is transmitted passes first above and then below the needle, so as to form two parallelpranches between which the needle is suspended, the settion of the current upon the needle will be similar in both cases. The upon the needle will be similar in doin cases. Ine force this produced is twice as much as that produced by a single conductor; if, however, the conductor be bent twice, the effect is four times as great; in short, by causing the conductor, usually made of wire, to make a very great number of convolutions, the action of the current upon the magnetized needle can be multiplied to such an extent that very feeble current; can readily be detected. In constructing an instrument of this kind, the copper wire used is covered with silk, so that the different convolutions may be juxtaposed and superposed without there being any direct metallic communication between them. The galvanometar has been greatly improved by Cumming, Nobili, and Melloni, and has been brought to a remarkable degree of delicacy. Other instruments used for the same purpose are Ritchie's torsion galvanometer, in which the magnetized needle is brought back by torsion to its normal position, and the angular distance passed over measured; since it follows that the intensities of the currents are proportional to the angles of torsion. force thus produced is twice as much as that produced currents are proportional to the augles of torsion.

M. Becquerel's electro-dynamic balance measures the strength of electric currents by means of a sensitive steel balance, which can turn at about a hundredth of a

strength of electric currents by means of a sensitive steel balance, which can turn at about a hundredth of a grain. Galvanometers are sometimes called Rheometers, from the Greek reo, I they; metron, a measure.

Gambie, or Gambier, gâm'-beer (after Gambier), a kind of catechu, prepared from the leaves of the Uncaria, or Nauciea Gambir, a plant of the ord. Cinchonacea, and a native of Malscoa and the Indian Archipelago. It is sometimes called pale terra-japonica, and by druggists catechu in square cakes. It is one of the most powerful of astringents, and is largely employed in tanning and dyeing; also in medicine.

Gambir, gâm'-bit, a word derived from an old Italian phrase, used to signify the tripping up of an adversary in wrestling. It is applied in the game of cheas to the first move, by which the player puts forth a pawn caprise, in order to force his antagonist to take it, and thus allow him, the first player, to bring forward his superior pieces sconer than he could otherwise have done. There are several gambits; but the one which is the most important is what is termed the "king's gambit." It is said by an experienced player of the is the most important is what is termed the "king's gambit." It is said by an experienced player of the intricate game of chess, that the most brilliant and animated of all openings are those performed by means of gambits. They are full of risk, but, to a dashing player, they afford time and opportanity for some of the best combinations on the board. (See Chess.)

Gambling, or Gaming, gam'-bling, gai'-ming (Sax. gamian, to risy at any sport), is a vice which has been common among most nations, civilized and novivilized.

common among most nations, civilized and uncivilized. Tacitus tells us that the ancient Germans were so ad-Tacitus tells us that the ancient Germans were so addicted to it, that, when stripped of everything else, they would stake at last their iberty, and their very lures, the loser going into voluntary slavery, and though much younger and stronger than his antagonist, suffering himself to be bound and sold. In Rome, particularly during the empire, the practice was common, and various enactments were made against it. In England, various enactments were made against it. In England, also, gaming was early made the subject of penal enactments. By 33 Henry VIII. c. 9, "ano person shall, for his gain, lunce, or living, keep any common house, alley, or place of bowling, coyting, cloyth, cayle, half-bowls, tennis, diceing-table, carding, or any unlawful game then or thereafter to be used, on pain of forfeiting 40s. a day;" and every person haunting or using the asid houses was declared to forfeit 6s. 8d. By 9 Anne, c. 14, all bonds and other securities given or using the said houses was declared to forfeit 6s. 8d. By 9 Anne, c. 14, all bonds and other securities given for money won at play were declared to be void, and any person losing £10 at one time or sitting might, within three months, recover the same, with costs, a any court of record; and after three months any other person might sue for and recover the same, and trebbe the value thereof, with costs. Various statutes were subsequently enacted on this subject; and in 1845, Act 8 & 9 Vict. c. 109, was passed, which greatly facilitated proceedings against common gaming-houses. It enacted that, in default of other evidence, it shall be sufficient to prove that a house or place is kety or used parallel to its axis, makes has needle turn to the east subsequently enacted on this subject; and in loss, Acc or west according as it is moving in a direction from north to south or from south to north. If the current is below, it causes the needle to turn to the east when it is moving from south to north, and to the west when it is moving from north to south; it follows, therefore, that when the conductor through which the is not necessary, in order to constitute the house a

common gaming-house, to prove that any person found playing attenty game was playing for any money, wager, or stake. Commissioners of police, or justices of the peace, may also authorize superintendents, without the necessity of an allegation by two householders. without the necessity of an allegation by two nonse-holders, to enter any suspected room or house with constables, and, if necessary, to use force for that pur-pose, and to take into custody all persons found therein; and if any cards, dice, balls, counters, tables, or other instruments of gaming, be found in the room or house, or about the person of any of those found therein, it shall be evidence, until the contrary be made therein, it shall be evidence, until the contrary be made to appear, that it was a common gaming-house. This statute also enacts, that cheating at play is to be deemed obtaining money by false pretences, and is to be punished accordingly. It further provides, that all contracts or agreements, whether by parole or in writing, by way of gaming or wagering, shall be null and void; and that no suit shall be brought or maintained in any court of law or equity, for recovering any sum of money or valuable thing alleged to be won upon a wager. By 16 & 17 Vict. c. 119, "betting-houses" are declared to be within this act, and a penalty imposed on persons so betting. The act 18 & 19 Vict. c. 38, enacted penalties and imprisonment against any person attempting to interfere with the against any person attempting to interfere with the constables in the performance of their duty, or obstructing their entrance into any house regarding which there was evidence of its being a common gaming-house. Notwithstanding all these legislative enactments, there still exist within this metropolis not a few of those gaming-houses, and which go by the appropriate name of "hells." In most of the states of Germany gaming is allowed, and the sovereigns of several of them derive a large revenue from letting the exclusive privilege of keeping such establishments, as at some of the more fashionable watering-places. In at some or the more fashionable watering-places. In France, prior to 1858, when the practice was abolished, the exclusive right of keeping public gaming-houses was let out to a company, who paid the government six millions of francs annually for the privilege. Much valuable information on this subject was obtained by the select committees of the House of Commons on

valuable information on this subject was obtained by

gaming, in 1844. (For further information see also the
English Cyclopadia, section Arts and Sciences.)
GAMBGE. (See CAMBGE, GARCINIA.)
GAMB LAWS are a remnant of the ancient forest
laws, by which all game was regarded as the property
of the king, and no person had any right to kill such
animals unless authorized by royal grant of a chase or
free warren. Afterwards, a right to kill game was conceded to such as possessed a sufficient qualification; as,
(1) the having a freehold estate of £160 per annum;
(2) a leasehold for ninety-nine years of £150 per annum;
(3) being the son and heir-apparent of an esquire or
person of superior degree; (4) being the owner or keeper
of a forest, park, chase, or warren. For unqualified
persons transgressing these laws by killing game,
keeping engines for that purpose, or even having game
in their custody, various penalties were assigned. At
length, after much discussion in and out of parliament,
nct 1 & 2 Will. IV. c. 32, was passed, by which the
necessity of any qualification for the killing of game
was abolished, and the right was made to depend simply
on the taking out of a game certificate, for which a
certain annual sum was payable. In terms of this act,
every certified person may kill game, subject to the
law of trespass. Game is declared to include hares,
pheasents, partridges, grouse, heath-game, moor-game,
plack-game, and bustarde: but woodcooks. mites. naw or trespess. Game a declared to include large, pheasants, partridges, grouse, heath-game, moor-game, black-game, and bustards; but woodcooks, snipes, quails, landrails, and conies, though not game, are slap protected, certificates being required to kill them.

#### Game Laws

conviction. When any person shall be found upon any land in the daytime in search of pursuit of any game, it shall be lawful for any person having the right of killing game, or the occupier of such land, or any person authorized by them, or either of them, to require such person forthwith to quit the land, and also to tell his name, surname, and place of shode; or, if he refuse to do so, or remain upon the land, he may be apprehended and brought before a justice of the peace, and shall be liable, upon conviction, to pay a sum of money not exceeding £5, with expenses; but the person so apprehended cannot, on any pretence whatever, be detained longer than twelve hours until he be brought before some justice of the peace. If any unsuthorized person be found, either by day or night, upon any land in search or pursuit of game, and shall then have in his possession any game which appears to have been recently killed, any person having the right to kill game upon such land, or the occupier of such land, or any person or persons authorized by them, may or any person or persons authorized by them, may demand such game, and seize it if not immediately given up. The destruction or taking away of the eggs of any bird of game, swan, wild duck, teal, or widgeon, renders the person liable to a penalty not exceeding 5s. for each egg so destroyed or taken away. The law is still more severe against any persone taking or destroying game by night. By 9 Geo. IV. c. 69, it is declared, that if any person, by night, shall take or kill game or rabbits on any land, or shall enter thereon with gun, net, ngine, or other instrument for the purpose, he shall, upon conviction before two justices, be committed to hard labour in the house of correction for a term not exceeding three months; and at the given up. The destruction or taking away of the eggs committed to hard insour in the house of containing for a term not exceeding three months; and at the expiration of that period find securities for twelve months, himself in £10, and one or two others in a like sum; in default of which, a further term of imprisonments. expiration of that period find securities for twelve months, himself in £10, and one or two others in a like sum; in default of which, a further term of imprisonment of six months. Offenders under this act may be apprehended on the spot by owners or occupiers of lands, their servants or assistants; and if they assanlt or offer violence with gun, olub, stick, or otherwise, they are liable to be transported for seven years (now penal servitude), or to be imprisoned, with hard labour, for two years. The punishment is still more severe where three or more persons enter any land for the purpose of taking or destroying any game. By 8 & 9 Viot. c. 29, the provisions of this act were extended to persons taking or killing game upon the public roads of highways, and other roads and paths leading to inclosed gates, &c. it is unlawful for any person whatsoever (licensed or unlicensed) to kill or take any game, or to use any dog, gun, net, or other engine or instrument for killing or taking any game, on a Sunday or Christmas-day, under a penalty of £5; it is also unlawful for any person to kill or take any participe between the 1st February and 1st September in any year, or any pheasant between the 1st February and 1st October in any year; or any black-game between 10th December and 20th August in the succeeding year (except is Somerset, Devon, or New Forest, Southamptonshire, to 1st September); or any ground, whether open or inclosed, or in any highway, with intent to destroy or nijure any game, shall be liable to a penalty of £1 for each head of game so taken or killed. To put any poison, or poisonous ingredient, on any ground, whether open or inclosed, or in any highway, with intent to destroy or nijure any game, shall be liable to a penalty of £10. Act 25 & 28 Viot. c. 114 (1862), authorizes any constable or peace officer of any county, borough, &c., in Great Britain or Ireland, to search in any highway, street, or public place, any person whom he may have good cause to suspect of having been unlawfully in search or pur 

is payable annually to government. An annual game-license costs £3, but one for about half a year may be had for about £2. A gamekeeper's license costs £2. By 11 £ 12 Vict. c. 28, an owner or compiler may, how-ever, kill harse or rabbits on his own inclosed ground, ever, and maries another to do so, without any game-lisanse. Such are the principal legal enactments in force on this subject at present. The game laws have long been a subject of discontent, and few unprejudiced persons can view them without coming to the conclusion that they are unreasonably oppressive and severe They are a remnant of the ancient feudal system, and Biackstone says, in speaking of the ancient forest laws, "from this root has sprung a bastard slip, known by the same of the game law, now arrived to, and wantoning in, its highest vigour, both founded upon the same unreasonable notion of permanent property in wild creatures, and both productive of the same tyranay to the commons; but with this difference, that the forest laws established only one mighty hunter throughout the land, the game laws har raised a little Minrod in every manor." The game laws are isdeed an attempt fourcestre, in the midst of oultivation and civi-They are a remnant of the ancient feudal system, and axempod in every manor. The game naws are naced an attempt to preserve, in the midst of oultivation and civilisation, the pursuits and amusements of an earlier and a ruder age. They are among the greatest hindrances to the improvement of agriculture, not only in many cases interfering with the operations of the cultivator, but, where plentiful, also causing a serious loss in the actual products. It is said that from three to five hares eat and destroy as much as would keep one sheep. The game is fattened at the tenant's expense, and the land-lord derives all the advantage from them. Many landlords take means to preserve game which none but tenants in a wretched state of dependence would submit to. Further, it has been said that "there is perhaps no single cause more injurious to the morals of the rural populations than the game laws." They constitute that an offence which neither conscience nor common sense can regard to be one; for the peasant does not naturally see any more right of property in a partridge than in a sparrow, nor can he understand that right of property which only continues anderstand has right of property which only continues so long as the animal remains upon a person's land. It is an unfortunate peculiarity of these laws, as protecting not property but a privilege, that they caunot be enforced without arming man against man, and producing conflict and bloodshed. The evidence of the crime is the capture of the committer of it in the act; and hence has arisen an armed game-police, acting not under a public responsible authority, but commanded in each instance by their private employers and owners of the soil. Offences, too, against the game laws are decided upon and punished by a class whose prejudices, if not their interests, favour a stringent application of the provisions of the code. The offender, too, be brought to associate in prison with theirers and housebreakers; and even though he may not have been directly contaminated by them, he not have been directly contaminated by them, he cannot be expected to have the same horror for the baser crimes as he had before. It has indeed been said that the sports of the field are favourable to health, strength, and high spirit. This may have been true of the old system, but it can scarcely, we should think, be said of the modern system of battue shooting,—the woods and plantations being beaten by men and boys, the game driven within gunshot, and attendants loading the sportsmen's guns, so that many hundred heads of game are slaughtered in a few hours.—Hef. English Cyclopadia—Arts and Sciences; Encyclopadia Distances; Paterson's Game Laws of the United Kingdom.

GAMES. gains (Sax. games. diversion. sport. pas-

Games, gaims (Sax. gaman, diversion, sport, passime), a term applied to certain bodily exercises and meantal vectorations practised as a relaxation from business or study, or employed as a mode of passing the time. They are divided naturally into two classes, mental and physical, but more definitely they are distinguished as games of chance, games of skill, and mixed games. In the first class the result does not depend upon the attention and deterrity of the player, but is merely determined by chance; it includes games played with dice alone, such as hazard, and many of the games played with cards, such as quinze, vingt-etm, languenet, commerce, loo, &c. The second class semprehends those games which, when once begun,

are independent of chance, and are gained by the superior skill and experience of out party. In many games of this kind, however, where the skill of the parties is equal, he who plays first is most frequently the winner. There are very few mental games of this class; but chess and draughts hold the highest places. It includes several interesting and popular physical games; among others, cricket, curling, bowling, golf, tennis, billiards, &c. In the third class the games are generally decided by chance where the players are generally decided by chance where the most important of these are whist, cribbage, piquet, casino, all-fours, and backgammon. Some games are very ancient, and dice were very early used by the ancient Greeks and Romans. Among the latter a game was played closely resembling the modern hazard. They had to work and so dice—the tesser and the tall; the former were exactly similar to modern dice, marked with Roman numerals on the sir sides; the latter were oblong pieces of bone marked on four sides only. The game of chess is also very ancient, and is supposed to have had its origin in the East. (See Craxes.) The several games at cards are modern in their origin; they are said by some to have been invented about the close of the latte entury for the musement of the French monarch Charles VI., while others place the French monarch Charles VI., while others

spectacles of varied kinds celebrated by the ancients, which, in the earlier ages, were connected with religious ceremonials. The public games of the Greeks were very numerous, and the origin of many of them is lost, on account of the religious mystery in which they were founded. Among the Grecian games, the most celebrased were the Olympic, the Pythian, the Nemean, and the Isthmian. The conquerors in the Olympic games were held in high respect, and were looked apon as the noblest and happiest of men. These games were held every five years at Olympia, in Elis, on the west side of the Poloponnesus. Among the exercises, some were designed to give strength, and others agility. The lighter exercises comprised runing, leaping, throwing the quoit, and hurling the javelin. The more severe course of discipline included wrestling and boxing. Racing also constituted a particular feature in all the ancient games. The Isthmian games were held at Corinth, and, together with athletic exercises, horse and chariot races, constituted a large portion of the spectacle. Originally these games were connected with the worship of Neptune, the wide diffusion of which gained for them the great celebrity which they long enjoyed. The Persian war gave an impulse to the Isthmian games, while the Peloponnesian war dimmed their glory. Under the Romans, these cames did not lose their importance, but were exhibited with increased calebrity. They were then held every three years, and comprised three leading divisions,—musical, gymnastic, and equestrian contests. The prize at the Olympic games was merely a chaplet of wild olive. These chaplets, together with branches of palm, which were carried in the hands of the victors, were placed on a tripod in the middle of the course, so as to be seen by all the spectators. At the Isthmian games, the prize was partier during the mythic periods; in later times, however, the victor was generally crowned with a wreath of pine-leaves, although parsley was also often employed. The amusements in the Roman circu

terially from those which were selebrated in the games of ancient Greece.\* The thericonachia, or beast-fight, was a favourite species of entertainment among them; and the men employed in this barbarous amusement, in which men fought with wild beasts, were called bestiarii. The combatants were divided into two classes,—those who fought voluntarily for amusement or pay, and who were provided with weapons,—and condemned persons, who were generally exposed to the fary of the animals naked, without arms, and sometimes bound. The Romans were passionately fond of these beast-fights, and very large numbers of animals were emgaged in them. Under Pompey, no less than 600 lions were thus destroyed; and under Titus, 6,000 wild and 4,000 tame animals perished us a similar manner. There is no doubt that, although these latter exhibitions produced a debasing effect upon the minds of the beholders, the athletic games of the ancients not only improved the physical development of the people, but tended directly to advance their intellectual and moral oulture. The early and long training by which they were preceded, and the long training by which they were preceded, and the exercises through which the child, the youth, and the man were conducted by successive stages, ultimated at length in that union of beauty and strength in which physical perfection consists, and in which the ancient Greeks surpassed every other known nation.

ancient Greeks surpassed every other known nation.

Gaming. (See Gamille).

Gaming. (See Gamille).

Gaming. Gaming. A term applied to the table or scale invented by Guido d'Arrezzo, from his having adopted the gumma, or third letter of the Greek alphabet, as a sign for its lowest note, which was one note below the proslambanomenos, or lowest tone of the ancients. It consisted of twenty notes, viz., two octaves and a major sixth. In modern music, the term gamat signifies the distortion scale and is occasionally applied to the the diatonic scale, and is occasionally applied to the note G below the bass clef.

GARGLION, gång'-le-on (Gr.), in Anat., is a small rounded or elongated nervous mass, of a reddish-grey colour, situated in the course of the nerves. They are of two kinds, one forming part of the cranial system of nerves, and situated near the origins of many of the cranial and all of the vertebral nerves; the other forming part of the sympathetic system, extending in a series along each side of the vertebral column, and occurring numerously in other parts. They differ series along each side of the vertebral column, and occurring numerously in other parts. They differ widely from each other in figure\_saud size, some of them being large and conspicuous, while others may be almost termed microscopic. They are composed of two substances, one white, like the medullary matter of the brain, the other reddish-grey, somewhat resembling the cerebral cortical substance. The internal medullary filaments are the continuation of the nerve upon which the ganglion is situated; they are invested externally by a thin but firm and closely-adherent envelope, continuous with the sheath of the nerves, and composed of dense arcolar tissue. This outward covering sends processes inwards through the interior mass, ing sends processes inwards through the interior mass ang sense processes investe through a the interior mass, dividing it, as it were, into lobules, and supporting the numerous fine vessels which pervade it. A section through a ganglion in the direction of the nervous cords connected with it discloses to the naked eye merely a collection of reddish-grey matter, traversed

cords connected with it discusses to the mater cyc
meresy a collection of reddish grey matter, traversed
by the white fibres of the nerves.
Ganglion, in Surg., is a small indolent fluctuating
tumour, developed in the course of the tendons,
and containing a semi-fluid secretion inclosed in a
cyst, generally communicating with the tendonous
sheath. They sometimes form without any apparent
cause, but generally they arise from some wrench or
tension of the tendon. They are most frequently
globular; but when much enlarged, it is rendered irregular by the pressure of the tendons. The treatment
consists in rupturing the cyst, and allowing the contained fluid to be extravasated into the cellular tissue,
where it is speedily absorbed, whilst the cyst inflames
and becomes obliterated. A common mode of rupturing them is either by firm compression with the
thumb, or by striking the swelling sharply with some
obtuse body, as the back of a book, the part being
subsequently bandaged, and rest enjoined for a few
days.

GANGREET, gang'-green (Gr., From grao, I feed upon), in Med., is a term applied to the first stage of morti-

fication, so called from its enting way the flesh. It is divided into two kinds, the moist and the dry; the former, called also inflammatory or acute gangrees, is that which is preceded by inflammation; while the latter, called also chronic or idiopathic gangrees, is that which takes place without any visible inflammatory action having preceded it. The most frequent causes of gangrees are violent inflammation, cryspelss, causes of gangrene are violent inflammation, crysic contusions, burns, cold, deficient circulation of the blood or nervous energy. When it results from high and active inflammation, there is at first severe pain and acover innammation, there is at first severe pain in the part attacked, and generally n considerable degree of swelling. After a time, however, the part, from being painful, loses all sensibility and becomes cold, the reduces disappearing, and being replaced by an irregular dark colour of the skin, in some parts cold, the reduces disappearing, and being replaced by an irregular dark colour of the skin, in some parts approaching to black, while in others it is of a dark brown or greenish hue. If there is a running sore, the discharge from it will cease; the cuticle is raised by vesications, from which, on breaking, there issues a bloody serum. The constitution sympathises with these local changes; the inflammatory fever of the tense to an enarges; the innammatory rever of the earlier period disappears, and is succeeded by great languor and debility; the pulse is weak, quick, irregular, and sometimes intermittent; the stomach is deranged, delirium frequently occurs, and hiocough is one of the most characteristic signs of the disease in its more advanced stage; the countenance also indicates the existence of great local and constitutional derangement, the features are collapsed and the eyes sunk. When the gangrone is not the result of high and active inflammation, the inflammatory or febrile symp-toms are slight or altogether wanting; but there is the same discoloration of the skin, vesication, discharge of bloody serum, and morbific appearance. In the trestsame disconvention of the skin, vestication, discharge of bloody serum, and morbific appearance. In the trestment of this disease, during the active inflammatory stage, local bleeding with leeches, and also bleeding from the sam, if the strength of the patient warrant it; but care has to be taken to reduce the general tone of but care has to be taken to reduce the general tone of the system as little as possible. Soothing fomentations and warm poultices should be applied to the part; and, as internal remedies, bark, wine, and opium will be found most beneficial. When the gangrena cannot be stopped in its first stages, then the separation of the mortified parts is to be expedited, which is best done by yeast or port-wine poultices, supporting the constitution at the same time. When this cannot be done, the removal of the limb, if practicable and not contra-indicated by a too-wakened state of the body, is the only chance of saving the patient's life. Gangrene resulting from severe cold is remarkable for the little pain generally preceding, the part having frequently resulting from severe cold is remarkable for the little pain generally preceding, the part having frequently periahed without the patient being aware of the circumstance. A part suffering from a severe degree of cold should first be rubbed with snow or a coarse towel, in order to restore the suspended circulation, avoiding at first any artificial heat, which might be the means of inducing inflammation. Gangrene may also arise from a diseased state of the blood-vessels, attended with debility of the constitution, a form of the disease commonly known as gangrena senitis. It rarely occurs except in advanced life, and neually attacks the lower extremities, proceeding from the toos nowards. occurs except in advanced life, and usually attacks the lower extremities, proceeding from the toes upwards. Its progress is sometimes slow and sometimes rapid; in some cases it is attended with little or no pain, in others it is very painful. As the parts mortily, they become dry and hard. The constitution should be strengthened by the free use of bark, opium, and port wine, and the part should be covered with lint moistened with campaignated spirits of wine, and the limb wrapped in cotion. Hospital gangrene, or phagelena gangreness, is a form of this disease which attacks open wounds or ulcers, and is so called from its appearing most frequently in crowded hospitals, and sausing a fearful mortality among the patients. Its symptoms and treatment are similar to those already mentioned. already mentioned.

already mentioned.

Gangway, gdng'-way (Ang.-Sax.), a term used in Mar. to denote a peasage or thoroughfare of any kind. In deep-waisted ships, it designates a narrow way built horizontallyshing the upper part of a ship's side from the quarter-deck to the forecastic.

Gangur, gang (derived from Ger. gang, a channel or vein), the mutrix or veinstone of ores. These are always included in some stony matter which forms the

principal portions of the veins or beds which are worked for the sake of their metalliferous contents. worses for the most common veinstone, and has been called the mother of ores. Calearons spar is also a frequent predominant material of veins. Sulphate of barytes, or heavy spar, and fluor spar, are also found as gangues. found as gangues.

GANNET, Or SOLAN GOOSE, gan'-net (Sax. ganot).— In the north of Scotland, the Hebrides, and in Nor-In the north of Scotland, the Hebrides, and in Norway, this bird is very abundant. It is almost the size of the tame goose. The bill is about six inches long, jagged at the sides, and straight nearly to the point, where it inclines downwards. A loose skin, bare, and capable of considerable distension, hung from the blade of the lower bill, and extended over the throat, serves as a pouch in which to convey food to its young. The neck of the gannet is long; body flat, and very full of feathers. The crown of the head and a small space of the hind part of the neck are helf-colour, and full of feathers. The crown of the head and a small space on the hind part of the neck are buff-colour, and, with the exception of the quill and the bastard wing-feathers, the remainder of the plumage is white. The legs and toes are black, but the forepart of-each is marked with so bright green stripe. The male and female are nearly alike. The young are at first covered with very beautiful snow-white down; at the age of about six weeks, the feathers make their appearance, and at the end of three months they are ready to fly. The food of the gannet consists of salt-water fish, the herring and pilchard being the staple. It takes its prey by darting down on it from a considerable height. It makes its nests, which are composed chiefly of turf and sea-weeds, in the caverne and fissures of rocks or on their ledges, as well as on composed chiefly of turf and sea-weeds, in the carerns and fissures of rocks or on their ledges, as well as on the plain surface of the ground. The female lays three white eggs, somewhat smaller than those of the goose. It is stated, however, that the three eggs are only laid in the event of the first and second being removed; and that if left to its own devices, the bird will lay but one egg. These birds are found in great abundance on the island of Kilds, a little spot standing remotely westward in the Atlantic Oceau. The annual "yield of hirds is computed at from ventry to effect thousand of birds is computed at from twenty to fifty thousand, while the egg crop is almost incalculable. The most favourite resort for these sea-fowl, according to the late Bishop Stanley, is a tremendous precipice about thir-teen hundred feet high, formed by the abrupt termination of Conadean, the most elevated hill in the island of Britain. The great dependence of the egg-takess are ropes of two sorts,—one made of strips of hide, the other of the hair of cows' tails, all of the same thickness. These ropes vary in length from fifty to two hundred feet, and sre three inches in circumference. So valuable are these ropes, that a St. Kilda swain marrying a damsel whose dower is a good long cowtail-hair rope, considers that he has made rather a splendid match. The scientific name of this bird is Sula Bassana.

GAOL, or JAIL, jail (Fr. geol; Sp. jaula, a cage) (See PRISON.)

GAOL DELIVERY is a commission directed to the justices of assize, &c. of each circuit, empowering them to try and deliver every prisoner who may be in gaol when they arrive at the circuit town, whenever gaoi when they arrive at the circuit town, whenever or before whomsoever indicted, or for whatever crime committed. In this respect their authority differs from that of justices of oyer and terminer, who can proceed only upon indictment found before themselves. Gables, gar-bi (Fr. garber, to make clean), in Law, signifies to separate or sever the good from the bad,

the sufficient from the insufficient. Hence in London the garbler of spices was anciently one empowered to enter into any shop, warehouse, &c. to view and search drugs and spices, and make clean the same, or see that it be done.

That it De Gone.

GARCINIA, gar-sin'-e-d (in honour of Dr. Garcin, an oriental traveller), in Bot., a gen. of the nat. ord. Guttifera. The species G. manyostana, a native of Malacca, produces the mangosteen, which is reputed to be the most delinious of all fruits. This plant has recently been brought to bear fruit in stoves by British hortinulturists.

an application to chapped hands, and has been recently imported into this counts. One or more species of this genus are supposed to yield our commercial and official gamboge, which is brought from Siam in cylinders, either solid or hollow, and in large cakes or amorphous masses. The pipe, or roll gamboge, is the finest kind. In medicine, gamboge is used as an active hydragogue and drastic purgative. In over-doses it acts as an acrid poison. In the arts it is much employed as a water-colour, and to give a golden tint to lacquer-varnish for brass-work.

Gandenia, gar-de-ne-d. in Bot., a gen. of the nat. ord. Cinchonacea. From the fruits of G. grandifora, florida, and radicans, beautiful yellow dyes are prepared, which are extensively used in China and Japan. The genus was named after Dr. Garden, of Charleston, South Carolina, who corresponded with Linneus.

GARDENING, gar'-den-ing (Fr. jardin, a garden), the act of laying out and cultivating pieces of ground, generally of limited extent, and inclosed for the purpose of rearing vegetables, fruits, and flowers. As an of rearing vegetables, fruits, and flowers. As an art of design and taste, gardening is of very ancient date, and with the exception of certain modern improvements, such as glass-houses, &c., was in a high state of perfection two thousand years ago. The earliest gardens of which there is any account are those of Solomon, which are described as having been of quadrangular form, surrounded by high walls. They contained aviaries, wells, and streams of water. The gardens of Cyrus and other Persian monarchs were of creat extent and generally laid out in romantic situation. gardens of Cyrus and other Persian monarchs were of great extent, and generally laid out in romantic situations. They were also distinguished for the great diversity of their uses and products. The first allusion to terraces in gardens is to be found in the description of the celebrated hanging gardens of Babylon. Although Herodotus and others do not mention it in their descriptions, there is little doubt that these terraces were decorated with vases, parapets, &c. Most of the elements of a modern architectural garden are alluded to in connection with those of Babylon. The terraces are described as being furnished with groves, containing fountains, seats, parterres, and banqueting-rooms, and as combining the minute beauties of flowers and foliage with masses of light and shade and existantive prospects. The grove of beauties of flowers and foliage with masses of light and shade and expansive prospects. The grove of Orontes, described by Strabo, must be regarded as a park or large garden in the picturesque style: it was nine miles in circumference. In ancient Greece gardening was rather a neglected art at first, but in process of time great advance was made. The vale of Tempé, the Academus at Athens, and other public gardens, were extremely elegant, and were ornamented with temples alters towns gaters monuments and with temples, altars, tombs, statues, monuments, and towers. On account of the nature of the climate, the towers. On account of the nature of the climate, the chief qualities required in a garden were shade, concess, fresh breezes, fragrance, and repose. The Greeks copied their gardening from the Persians, and the Romans, in their turn, copied that of the Greeks. Little is known of the early style of Roman gardening: the vast edifices projecting into the sea, and the immense artificial elevations, are apparently ridiculed by Cicero and Varro. About this time, however, the cultivation of odoriferous trees and plants began to be attended to; and the planting of trees adjoining each other, whose odours assimilated, was then as much a study with the gardener as the harmonious blending of colours at the present day. The early French and a suny with the gardener as the harmonious blending of colours at the present day. The early French and Dutch styles of gardening were evidently adopted from the description of Pliny's garden. On this subject Loudon remarks:—"The terraces adjoining the house, the lawn declining from themes, the little flower, and any with the fountain in the centre the walks had and so the iswn declining from theence, the fitte howers garden with the fountain in the centre, the walks bordered with box, and the trees sheared into whimsical artificial forms; together with the fountains, alcoves, and summer-houses, form a resemblance too striking to bear dispute." The use of glass in the construction to be the most delicious of all fruits. This plant has creently been brought to bear fruit in stoves by British the construction and the fruit in stoves by British the construction in horticulturists. G. cornea, Kydiana, and pedan-culata yield fruits of a similar character, but much inferior. The seeds of G. purpura, upon being rare trees from India and China, the myrtle and boiled in water, yield a concrete oil called kokum crocus in flower, and the cinnamon and frankincense butter, or oil of mangosteen. It is very useful as trees covered with leaves. Cucumbers were also

#### Garfish

grown there all the year round. The use of hot water in forcing vegatalies was also employed at the same time. Gardening, like all the other arts, languished during the dark ages; but with the revival of learning, the invention of printing, and the Reformation, it began again to flourish. The art was revived and patronised by the family of the Medici in Italy; and their gardens, which were of the geometric and architectural style, long served as models for most of Kurope. It continued to be imitated in France, Germany, and Britain, until the introduction of the English or natural style. In garden architecture very little progress, as far as hothouses are concerned, has been made in the south of Europe, the warmth of the climate rendering them all but useless. There are, however, plant-houses in many places in Spain and Portugal. The French and Dutch styles of gardening resemble each other closely: symmetry and profuse ornament are the characteristics of both. The Dutch style is eminently adapted to the nature of the country, where there are no inequalities of surface as in England. The French style seems to have arisen about the middle of the 17th century, during the reign of Lonis XIV. The most celebrated cardens of the in England. The French style seems to have arrived about the middle of the 17th century, during the reign of Louis XIV. The most celebrated gardener of the period was Le Notre, who laid out the famous gardens of Versailles. Le Notre's style spread rapidly into other countries, and was extensively adopted in this country. The first erection of hothouses in France of the reign of Louis XIV. of versalies. Le Noire sayle spread aspuny aucher countries, and was extensively adopted in this country. The first erection of hothouses in France cocurred towards the end of the reign of Louis XIV., by M. Fagon, in the Jardin des Plantes. The first magnificent attempt at hothouse-brilding was that of Francis I. of Austria, in 1753. They were in five ranges, extending altogether to the length of 1,290 feet, many of them being 30 feet high. Landscape gardening, and the sdoption of the English style, rapidly spread into France, Germany, and Russia, after the year 1762. In the latter country there are several magnificent conservatories, only surpassed by those of Kew, Chatsworth, and the Regent's Park, in this country. The first examples of the English, or natural style of gardening, were those of Pope at Twickenham, and of Addison at Bilton, near Rugby. But these were on a small scale. The higher examples were those of Stowe, Pain's Hill, Claremont, Esher, Hagley, and Woburn Farm, near Weybridge. The earliest hothouses for the cultivation of fruits seem to have been those of the duke of Rutland, erected at have been those of the duke of Rutland, erected at cave been those of the duke of Rutland, erected at Belvoir, in 1705. In modern times, the best-constructed, or most improved, kitchen and foreing gardens, are those of her Majesty at Frogmore. The Royal Botanic Gardens at Kew are unequalled in Europe, while those of Chatsworth, Eaton Hall, and Trentham, are models of taste and judgment. The art of cultivating flowers and fruits in gardening will be found more particularly described under the article HORHTCHYDEN. HORTICULTURE.

HORTCULTUER.

GABFISH, gar'-fish (Esox Belone, Linn.), a fish of the Pike fam., common on the English, Irish, and Scotch coasts. It is about two feet in length, body tapering towards the tail, and of small circumference; beak-like enout; teeth minute and numerous; tail considerably forked. It possesses many names besides that here applied to it, and among the rest, "mackerel guide," because of its supposed habit of preceding the shoals of mackerel in their annual visits to shallow waters for the nurroes of snawning.

or macrered in their annual visits to snahow waters for the purpose of spawning.

GARGLE (Lat. gargarisma, from Gr. gargarizo, I wash the throat), in Med., is a lotion or wash for the throat. It is used by taking a mouthful of the liquid, and then throwing back the head, by which it is passed into the throat, where, by expelling air from the lungs, it is agitated and made to wash all parts of the inner surface. Gargles are extremely useful in various diseases of the throat, and differ in their composition according to the nursues which they are intended to serve. of the throat, and differ in their composition according to the purpose which they are intended to serve. In order to allay inflammation or reduce swelling, warm water with a little vinegar is the best that can be used. When a stimulating effect is required, a mixture of capsicum; to promote suppuration, barley-water and inclusion of linseed used warm; and, as a pure astringent, a decotion of Peruvian bark, with alum or borax, will be found useful.

Gargoyle. or Gurgoyle. now. and [Fe required]

GARGOYLE, or GURGOYLE, gar'-goyl (Fr. gargouille), in Arch., the name given to an ornamental spout pro-

### Garrison

jecting below the battlements of a tower or the para-pet of a well, through which the rain that falls on the roof is discharged at a little distance beyond the face of the wall. The gargoyle forms a striking feature in the Early English and Decorated Rugish styles; being the Early English and Decorated English styles, being frequently in the form of a dragon, or lion, or some heraldic monster, and sometimes a grotesque representation of the human face and figure. It was introduced to mask the unsightly appearance of a piece of leaden pipe sticking out of the wall, the pipe being passed through a block of stone, which was subsequently carved into a form corresponding to the general character of the architecture of the building.

Garner, gar-net (Fr. grenat), in Min., one of the precious stones or gems. It is found in rhombic dodecahedra, and consists chemically of the double silicate of lime and alumina, coloured by iron and manganese. When cut en cabochon, garnets are known as carbuncles (from carbunculus, a little coal). The pryrope is a species of garnet found in Bohemia, coloured with seaquicitied of chromium.

Garnement, gar-nich-ment (Nor. garnisker, to earl) is a warning or notice given to a marky not to nearly

Girmsemmer, gor nich-ment (Nor. garnisher, to warn), is a warning or notice given to a party not to pay money, &c., to a defendant, but, to appear and answer to a plaintiff-oreditor's suit. By the Common Law Procedure Act of 1854, it is declared lawful for any creditor who has detained. who has obtained a judgment in any of the superior courts, to apply to the court, or a judge, for a rule or order that the judgment-debtor should be orally examined as to any and what debts are owing to him, before a master of the court, or such other person as the court or judge shall appoint; and the court or judge may make such rule or order for the examination the court or judge shall appoint; and the court or judge may make such rule or order for the examination of such judgment-debtor, and for the production of any books or documents. And it is lawful for a judge, upon the ex-parts application of such judgment-creditor, and upon affidavit by him, or his attorney, that judgment has been and is still unsatisfied, and that a third person is indebted to the judgment-debtor, and is within the jurisdiction, to order that all debts owing or accruing from such third person (called the garnishee) to the judgment-debtor, shall be attached to answer the judgment-debt, and the garnishee may also be ordered to appear before the judge, or master of the court, and to show cause why he should not pay the judgment-debt. If the garnishee does not forth-with pay into court said sum, and does not dispute the debt, the judge may order execution to issue without any previous writ or process; or, if the garnishee disputes his liability, the judge may, instead of ordering an execution, grant liberty to the judgment-creditor to proceed against him by writ, calling upon him to show cause why execution should not proceed against him for said debt. Payment made by, or execution levied upon the garnishee, under any such proceeding, shall be a valid discharge to him for such amount, as against the judgment-debtor, although the proceeding may be set saide or the judgment reversed.—Ref. Wharton's Law Lexicon.

Garatte, or Garatter, garatte, (Sp. garrote, a stick or Law Lexicon.

Law Lexicon.
GAROTTE, or GARROTE, ga-rot' (Sp. garrote, a stick or cudgel), is the name given to a kind of capital punishment employed in Spain. The criminal is seated on a stool, with his back to a stake, and formerly death was inflicted by means of a rope passed round his neck and tightened behind with a stick (garrote); but now an iron collar is commonly employed, tightened by a screw. The term has recently been adopted in this country, and applied to a mode of robbery, in which one ruffian from behind grasps tightly the victim's throat, so as to prevent him from crying out or making any resistance, while another rifles his pookets. An account of the mode of procedure in such cases will be found in the Cornhill Magazine for January, 1863.
GARRISON, gär-re-son (Fr. garnison, from the low

Cornhill Magazine for January, 1863.
GARRISON, gür'-re-son (Fr. garnison, from the low
Lat. garnison, ammunition, military stores), a term
applied to a body of troops stationed in any town or
fortified place, either to defend the position against an
enemy, to keep the inhabitants under subjection, or
merely to be subsisted. By military writers, the term
garrison is generally applied to a forto refortress, to
the body of troops or guard placed in a citadel, or to
any troop of soldiers quartered in a town.

909

GARRYAGRE, gon-re-av-se-e (after N. Gerry, of the Hudson's Bay Company), in Bot., the Garrya fam., a small nat. ord., of Dicotyledones, sub-class Mono-alkamydes. There are but two genera, which include six species, all shrubs found in the temperate parts of North America, or in the West Indies. Nothing is known of their properties.

known of their properties.
GARTER, ORDER OF THE, gar-ter (Fr. jarretière),
one of the most celebrated and ancient of all military
orders of knighthood in Europe, was instituted by
Edward III. The origin of this decoration is ascribed
to a trifting incident which occurred at a ball at which
the king and the countess of Salisbury were present.
The countess is said to have dropped her garter whilst
daming. the kine misking it up, and, observing some danning; the king picking is up, and, observing some of the courtiers to be smiling, restored it to the countess, with the remerk, Hons soit qui mal y pease, "Evil be to him who evil thinks;" and he shortly afterwards is said to have instituted the order of the Garter wards is said to have instituted the order of the traffer with the above motto, as an incentive to chivalry amongst his knights. Another account states that it dates its origin from the reign of Richard Cœur de Laon, who, during his battles in the Holy Band, ordered his knights to wear a white garter above their tenee, to distinguish them from their Saracen foes; and that Richard, on his return to England, instituted the order, in commemoration of that circumstance. Still, according to Ashmole, the date of the order is 1411; and, as the first of its statutes is dated 1450, this 1311; and, as the first of its statutes is casted 1400, thus seems tolerably securate; whence it follows that it was established in the reign of Edward III. Upon the original constitution of the order, it consisted of the sovereign and twenty-five heights companions. The only alteration which has taken place in this respect, only alteration which has taken place in this respect, was caused by the statute passed on the 17th January, 1805, whereby it was decreed that the order should consist, thenceforth, of the sovereign and twenty-five knights companions, together with such lineal descendants of George II. as may be elected, always excepting the prince of Wales, who is a constituent part of the original establishment. Special statutes have likewise been, from time to time, passed for the admission of foreign sovereigns and extra knights; but these are always admitted into the twenty-five companions as soon as yacancies occur. passed for the admission of foreign sovereigns and extra knights; but these are always admitted into the twenty-five companions as soon as vacancies occur. The Military Knights of Windsor are also considered as adjunct to the order of the Garter. The officers of theorder are, firstly, the Prelate, which dignity was first filled by William de Edyngton, bishop of Winchester for the time being; the office enabling him to take his seat in parliament next to the bishop of Durham. The next officer is the Chancellor, who, until the year 1337, was the bishop of Salisbury; but since the see of Oxford has included Berksbire (and consequently the town of Windsor), the chancellor is always the bishop of Oxford. The Registrar, who is dean of Windsor, is the next official; and after these we have the Garter Kingst-Arms (which see), and the Usher of the Black Red. All these officers are bound to attend the chapters of the order held in St. George's Chapel, Windsor, on St. George's Chapel, Windsor, on St. George's Chapel, Windsor, or St. George's day, where the installations of knights are held, and they are sworn to adhere to all the institutes of their shility. The peculiar dress which distinguished the order, and to promote its well-being to the best of their shility. The peculiar dress which distinguished the order of the Garter from other similar institutions, at its flest establishment, was a mantle, tunic, and of their shilty. The peculiar dress which distinguished the order of the Garter from other similar institutions, at its first establishment, was a mantle, tunic, and hood of bine cloth lined with ermine, that of the severeign differing from the knights by the fur of the lining being of miniver instead of ermine. All these three garments were embroidered with garters of blue and gold; and the garter itself was worn under the left knee, and was composed of dark blue velvet edged with gold, with the motio "Honi soit qui mal y pense" inferribed by it with letters of gold; the buckle and pendant were likewise of the same precious metal. Henry VIII. added a collar, composed of pieces of gold worked in the fashion of garters, the centres of each being alternately white and red (alluding to the junction of the York and Lancaster families in the house of Tador), and these links, or garters, were exactly twenty-six in number, typical of the strength of the order. He also added the greater and lesser Georges, which copies of gold medallions with the figure of St, George and the Dragon thereon in relief,

Charles II. made the last alterations, substituting crimson for the surcost and head, and a lining of white taffets instead of ermine. The ribbon by which the medallion of St. George is suspended over the left the medallion of St. George is suspended over the left shoulder is of blue,—whence the expression "receiving the blue ribbon," instead of being installed a member of the order of the Garter. Down to the reign of Edward IV, some hairs, as the queen, &c., were ad-mitted to share in the honours of this magnificent. mitted to share in the honours of this magnificent fraternity; and the splendid appearance of Queen Philippa, clad in some of the habiliments of the Garter, is mentioned by Froissart as very imposing. The dress and ceremonies are at present exactly as they were when first instituted, with the exception of the alterations above mentioned; and the Garter is still held to be, and will no doubt continue to hold its fame of being, the first order of the kind in Europe in every sense.

sense.

GARTER KING-AT-ARMS, the fourth officer of the order of the Garter, is rendered exceptional from the circumstance of his being also the principal officer in the College of Arms, and chief of the heralds. He was first elected by the universal consent of all the knights companions in the reign of Henry V. The services which he afterwards performed were previously done by the Windsor herald-of-arms, an officer orested by Edward III. The cath administered to him on done by the windsor nersia-or-arms, an omore created by Edward III. The oath administered to him on appointment is, to yield obedience to the sovereign and knights companions; to keep silence, and not disclose the secrets of the order; to make signification of the death of each knight companion; to execute faithfully all things committed to his care; to inquire diligently after all the noble acts of the knights companion; and armiting the secret of the knights companion. panions, and certify the same to the registrar; and, handly, said the same as that of the other offices. His dress is the same as that of the other officers, and differs but little from that of the knights of the order.

differs but little from that of the knights of the order. Gas, gis (probably from Ger. geist, a spirit), in Chem.—This word was first applied by Van Helmont to denote any permanent vapour produced from solid or liquid substances by chemical action. The elementary gases are,—bydrogen, oxygen, nitrogen, and chlorine. The principal compound gases are,—hydrochloric, hydrobromic, and hydriodic acids; sulphureas acid, nitrous acid, peroxide of chlorine, chlorous acid, hypochlorous acid, carbonic acid, sulphuretted, phosphoratted, seleminetted, and telluretted hydrogen; cyanogen, protoxide of sitrogen, deutoxide of nitrogen, earburetted hydrogen, olefisht gas, carbonic oxide, and ammonia.

ammonia.

GAS, MANUFACTURE OF.—The term gas is popularly applied to the important material which is produced by the destructive distillation of coal, those species by the destructive distillation of coal, those species being chosen which contain the largest amount of hydrogen. When coal is burnt in the open air, or in an ordinary stove, the principal products are carbonic acid and water, small quantities of ammonia and sulphurous acid, and finely-divided carbon in the form of phurous acid, and meey-civided caroon in the form of scot. When, however, coal is burnt in closed vessels, the products are much more numerous and complicated. The most important gaseous matters are marsh gas, olefant gas, hydrogen, carbonic oxide, carbonic acid, sulphurous acid, sulphuretted hydrogen, and ammonia. The liquid portions contain water, a nome soid, sinpurrous soid, sinpureretted syrrogen, and ammonis. The liquid portions contain water, a mixture of benzol, toluol, camol, and other hydrocarbons, commonly known as cond-ton mapthia, and dark viscous substance called coal tar. To render the gaseous products available for lighting purposes, all the shove-named, except the march gas and the elefant gas, must be abetracted, not only from their interfering with the illuminating power of the gas, but from their combustion being deleterious to health. Thecarliest attempts at illumination by this means were made by Mr. William Murdock in Cornwall, about the year 1792, who carried on his experiments for several years, until he succeeded in illuminating a large portion of the manufactory of Boulton & Watt at Soho, near Birmingham, to celebrate the peace of Amiens in 1802. Ten years afterwards the Chartered Gas Company made the first great experiment of lighting the streets with gas; from which time the employment of this material has gone on steadily increasing, until the whole of the large towns and most of the small towns of England and the contingat are illuminated by its means. The coal used for this purpose is that found

# Gas, Manufacture of

in the Durham coal-field, known as Newcastle coal, a in the Durham coal-field, known as Newcselle coal, a ton of which will yield nearly 10,000 cubic feet of gas, leaving behind shout 13 cwt. of coke of excellent quality. From Scotch coal is obtained a gas of higher illuminating power; but the quantity is smaller, and the coke produced is inferior. The average yield of coke is about 13 cwt. per ton. The process of manufacture is briefly as follows. Pit coal is heated in long flattened cylinders of clay or iron called retorts, arranged in long brick furnaces. The mouths of the retorts are fitted with morable ilds, which may be rendered air-tight by clay tubing. From the upper side of the end of each retort proceeds a tabe, which dips into a larger tube containing the tar and condips into a larger tube containing the tar and con-densed moisture called the hydraulic main. The gas passes through the tar and water, leaving a small por-tion of these substances behind it with a serpentine arrangement of tubes termed refrigerators, which arrangement of tubes termed refrigerators, which separate the remaining portions of water and tar. From the refrigerators it passes to the time-purifiers, which consist of large cylindrical vessels containing perforated shelves upon which the dry slaked lime is placed. Lastly, it passes through dilute sulphurio acid, by which means the last portions of ammonia are removed. In certain works the last washing with acid is superseded by a process termed scrubbing, which consists in passing the gas through a vessel filled with coke, upon which a stream of water is constantly trickling. The gas is stored in large reservoirs or gas-meters, the general shape of which is that of a cylinder, closed at the top, and floating, or suspended, with its open end in a reservoir of water. The dimensions of the gasometer are regulated by the geometrical law of the gasometer are regulated by the geometrical law that a cylinder has the greatest capacity with a given surface, when its height is equal to half its diameter; hence the capacity of the gasometer is such that, when raised to its highest point in the water, its height is equal to the radius of the base. It is customary, however, to increase this height by one or two feet in order to prevent the gas from escaping under the edge. Thus a gasometer capable of holding 30,000 cubic feet of gas has a diameter of 42 feet and a height of 23 feet. On account of the enormous consumption of 23 feet. On account of the enormous consumption, of gas in London and other large towns, the gas-works which supply them require to be provided with very large gasometers. They are made of sheet-iron plates, riveted, and coated with tar on both sides, in order to make the joints gas-tight. The covered cylinder is suspended in the water by means of a chain, and counterbalanced and guided by weights and wheels, so as to rise and fall with ease. Two tubes pass under and through the water reaching above its surface into as to rise and fall with ease. Two tubes pass under and through the water, reaching above its surface into the hollow of the gasometer. One of these admits the gas from the purifiers and the other carries it off when required for use. When full of gas, the gasometer is near the top of the water; and by lessening the counterbalancing weight, it is pressed down, and the gas forced out through the other pipe, which conveys it to the mains. As the gasometer voids the gas, it to the mains. As the gasometer voids the gas, it inks and fills with water, when it is again ready to receive a fresh supply of gas. Most gas-works are supplied with a number of gasometers, some filling, and others emptying; and nearly every gasometer is now furnished with some contrivance which indicates the exact quantity of gas which it contains. The gasometers above mentioned require a large space of ground, as so much depends upon the diameter of the ground, as so much depends upon the diameter of the cylinder. This fact led to the invention of the telescope gasemeter, which, with the same diameter, will hold a larger volume of gas without increasing the uses of the ground. This gasemeter consists of two, three, or more concentric cylinders, the bottoms and tops or more concentric cylinders, the bottoms and tops of which, except the uppermost, are furnished with flanges furned in opposite directions, the flange turning or outwards and upwards at the bottom, and inwards and downwards at the top. When the gas is introduced, the innermost cylinder rises first, and when its bottom flange catches the flange of the next cylinder, which also rises; and when this has risen sufficiently high it if its the next; and so on. The secape of gas and the admission of air are prevented by the lower flange of each cylinder taking up a quantity of water, which acts as water-late. These gesometers are usually anspended at three points in their circumference by three

### Gascomade

chains running over pulleys attached to three pairs of pillars. It is of the greatest importance that the temperature at which the gassis produced should be regulated with great nicety. If the temperature be too low, the coal distils into liquid hydrocarbons, whilst, if too high, a great portion of the gas is burned in the retort; besides which, bisalphide of carbon is formed, which cannot be got rid of by any known process, and which, when burnt gives rise to vapours of sulphurous soid, to the destruction of the furniture of the spatiment in which it is used. In the United States of America methods of taking supplies of gas in steamboats and on railroad cars have been for some time in operation. By one plan sheet-iron cases, of the capachains running over pulleys attached to three pairs of pillars. It is of the greatest importance that the operation. By one plan sheet-iron cases, of the capacity of 50 or 60 feet, are fitted under the cars, and filled, as occasion requires, from the street mains under ordi-nary pressure. The tops of the cases are lined with a lose sheet of india-rubber, which swells upwards as the gas flows in beneath. To expet the gas for use, air is forced in above the lining by the action of a meter running by clockwork under uniform pressure.
The clockwork is impelled by a spring, which is wound
up by hand, and the action is suspended whenever the
valves for the burners are closed. The motion of the valves for the burners are closed. The motion of the cars does not affect the regularity of the supply to the burners. From the permeability of all flexible sheets, this process cannot be regarded as entirely safe from danger of explosion. By the method of the New York Car and Steamhoat Gas Company the gas is first compressed by a force-pump into strong cylindrical gasholders, made of boiler-plate iron, and measuring 7 or 8 feet in length, by about 14 inches in diameter. By the pressure of twenty atmospheres in diameter. By the pressure of twenty atmospheres thus not into a space of five cubic 100 feet of gas is thus put into a space of five cubic feet. To secure a uniform rate of discharge when the cylinders are connected with the gas-pipes of the car or steamboat in which they are carried, a regulator of improved form is attached to the pipes, which the aperture through which the air passes is gradually made to enlarge with the diminition of pressure. In Jersey city a stack of cylinders, conpressure. In every only a scale of syndron, our neeted by small pipes, seve as a reservoir, into which the gas is pumped at a pressure of 450 lb. From this a pipe extends to the railway station—a quarter of a mile distant,—and as the cylinders attached beor a mile distant,—and as the cylinders attached be-neath the cars require a new supply, they are simply connected with this pipe and directly filled. The Meropolitan (Underground) Railway Company also light their carriages by means of portable gas, which is stored for use in cisterns piaced upon the roof of the vehicle. Gas as fuel.—Recently, gas has been applied in suitably constructed stores as a source of heat. Being under perfect control. and easily directed heat. Being under perfect control, and easily directed to produce the required effect, it has in many cases proved a most economical fuel. In summer it may be made to heat, in suitably-arranged apparatus, culi-nary and other utensils without materially adding to nary and other utensis without materially adding if the warmth of the apartment; while in winter, con-sumed in stores adapted for diffusing heat, it has been made to take the place of other fires; and the application is especially convenient when a fire is only occasionally required a little while at a time. In chemical laboratories gas has long been employed as fuel. It has been found particularly convenient for heating and complete and the distantion of the beating small crucibles; and by directing through the sygned burner in which it was consumed an annular concentric current of sir, intense heat has thus been attainable at any moment. It next came to be applied in many of the mechanical arts, and upright cylindri-cal stoves of sheet iron were contrived, in which the

cal stoves of sheet from were contrived, in which the gas, being ignited, heated by its combustion the tools placed for the purpose in the upper part of the atove. GARCONNADS, gds-con-said (Rr.), is a term used in the French language to denote a habit of boasting, or speaking beyond the truth in conversation. The name is derived from the province of Gascony, the inhabitance.

give the public an idea of the ability with which he had executed his task, gravely assured them that his translation was so much admired that it was to be translated back again into the language of the original

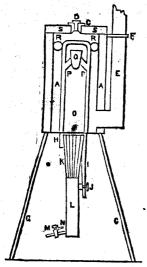

GASES, DIFFUSION OF. (See DIFFUSION OF GASES.) GASES, DIFFUSION OF. (See DIFFUSION OF GASES.)
GAS-EVERACE.—Messes. C. W. and F. Siemens have patented a regenerative gas-furnace, which promises to become of the highest utility. In a lecture delivered at the Royal Institution, on June 20, 1862, Professor Faraday thus described it:—"The gaseous fuel is obtained by the mutual action of coal, air, and water, at a moderate red heat. A brick chamber, perhaps air feet by twelve feet, and about ten feet high, has one of its end walls converted into a fire-reate.—i.e. about half down it is a solid plate and grate, ...i. e., about half down it is a solid plate, and for the rest of the distance consists of strong horisontal plate bars, where air enters, the whole being at an inclination such as that which the side of a heap of somal plate bars, where ar enters, the whole being at an inclination such as that which the side of a heap of coals would naturally take. Coals are poured through openings above upon this combination of wall and grate, and being fired at the under surface, they burn at the place where the air enters; but as the layer of coal is from two to three feet thick, various operations go on in those parts of the fuel which cannot burn for want of air. Thus the upper and cooler part of the coal produces a large body of hydrocarbons; the cinders, or coke, which are not volatilized, approach, in descending, towards the grate; that partwhich is nearest the grate burns, with the entering air, into carbonic acid, and the heat evolved ignites the mass above it. The carbonic acid passing slowly through the ignited carbon, becomes converted into arbonic oxide, and mingles in the upper part of the chamber (or gas-producer) with the former hydrocarbons. The water, which is purposely introduced at the bottom of the arrangement, is first vaporized by the beat, and then decomposed by the ignited fuel, and only the sabes of the coal are removed as solid matter from the chamber at the bottom of the fire-hare. The mixed cases form the cases form the and only the sakes of the coal are removed as solid matter from the chamber at the bottom of the firebars. The mixed gases form the gaseous fuel. The nitrogen which entered with the air at the grate is mingled with them, constituting about a third of the whole volume. The gas rises up a large vertical tube for about twelve or filteen feet, after which it proceeds horizontally for any required distance, and then descends to the heat-regenerator, through which it passes before it enters the furnaces. A regenerator is a chamber packed with fire-bricks, separated so as to allow of the free passage of air or can between to allow of the free passage of air or gas between them. There are four placed under a furnace. The to allow of the free passage of air or gas between them. There are four placed under a furnace. The gas ascends through one of these chambers, whilst air ascends through one of these chambers, whilst air ascends through the neighbouring chamber, and both are conducted through passage outlets at one end of the furnace, where mingling, they burn, producing the heat due to their chemical action. Passing onwards to the other end of the furnace, the combined gases find precisely similar outlets, down which they pass; and traversing the two remaining regenerators from above downward, heat them intensely, especially the upper part, and so travel on in their cool state to the shaft or chimney. Now, the passages between the four regenerators and the gas and air are like four waycocks in their action; so that by the use of a lever these regenerators and air-ways, which were carrying off the expended fuel, can in a moment be used for conducting air and gas into the furnace, and those which just before had served to carry air and gas into the furnace, now take the burnt fuel away to the stack. It is to be observed that the intensely heated flame which leaves the furnace for the tensely heated flame which leaves the furnace for the stack always proceeds downward through the regenerators, so that the upper part of them is most intensely ignited, keeping back, as it does, the intense heat: and so effectual are they in this action, that the games which enter the stack to be cast into the air are not usually above 300° F. of heat. On the other hand, the entering gas and air always pass upward through the entering gas and air always pass upward through the regenerators, so that they attain a temperature equal to a white heat before they meet in the furnace, and there add to the carried heat that due to their mutual chemical action. It is considered that when the furnace is in full order, the heat carried forward to be evolved by the chemical action of combustion is 913

### Gas-Furnace

about 4,000°, whilst that carried back by the regeneraabout 4,000°, whilst that carried back by the regenera-tor is about 3,000°, making an intensity of power which, unless moderated on purpose, would fuse fur-nace and all exposed to its action. Thus the regenera-tors are alternately heated and cooled by the outgoing and entering gas and air; and the time for alternation is from half an hour to an hour, as observation may indicate. The motive power on the gas is of two kinds—a slight excess of pressure within is kept up from the gas-producer to the bottom of the regenera-tor, to prevent air entering and mingling with the from the gas-producer to the bottom of the regenera-tor, to prevent air entering and mingling with the fuel before it is burnt; but from the furnace downward through the regenerators, the advance of the heated medium is governed mainly by the draught in the tall stack or chimney. Great facility is afforded in the management of these furnaces. If, whilst glass is in the course of manufacture, an intense heat is required, an abundant supplied of one and six is given; when the the course of manufacture, an intense heat is required, an abundant supply of gas and air is given; when the glass is made, and the condition of heat has to be reduced to working temperature, the quantity of fuel and air is reduced. If the combustion in the furnaces is required to be gradual from end to end, the inlets of air and gas are placed more or less apart, the one from the other. The gas is lighter than the air; and if a rapid evolution of heat is required, as in a short puddling furnace, the mouth of the gas inlet is required, as in the long tube-welding furnace, the recurred as in the contrary arrangement is used. Sometimes, as in the enameller's furnace, which is a long muffle, it is requisite that the heat be greater at the door end of the nuffle and furnace, because the goods, being put in muffle and furnace, because the goods, being put in and taken out at the same end, those which enter last, and are withdrawn first, remain of course for a shorter time in the heat at that end; and though the fuel and air enter first at one end and then at the other alter-nately, still the necessary difference of temperature is preserved by the adjustment of the apertures at those ends. Not merely can the supply of gas and air to the furnace be governed by valves in the passages, but the very manufacture of the gas-fuel itself can be but the very manufacture of the gas-fuel itself can be diminished, or even stopped, by cutting off the supply of air to the grate of the gas-producer; and this is important, inasmuch as there is no gasometer to receive and preserve the sëriform fuel, for it proceeds at once to the furnaces. Some of the furnaces have their contents open to the fuel and combustion, as in the puddling and metal-melting arrangements; others are inclosed, as in the muffle-furnaces and the flint-glass furnaces. The economy in the fuel is estimated practically as one half, even when the same kind of coal is used, either directly for the furnace or for the gas-producer; but as in the latter case the most worthless kind can be employed—such as slack, &c.,—which can be converted into a clean gaseous fuel at a distance from the place of the furnace, so many adwhich can be converted into a creat gaseous area as distance from the place of the furnace, so many advantages seem to present themselves in this part of the arrangement." Professor Faraday concluded his lecture with the following statistics:—Carbon, burnt lecture with the following statistics:—Carbon, burnt perfectly into carbonic acid in a gas-producer, would evolve about 4,000° of heat; but if burnt into carbonic oxide, it would only evolve 1,200°. The carbonic oxide, in its fuel form, carries on with it the 2,900° in chemical force, which it evolves when burning in the real furnace with a sufficient supply of air. The remaining 1,200° are employed in the gasproducer in distilling hydro-carbons, decomposing water, &c. The whole mixed gaseous fuel can evolve about 4,000° in the furnace, to which the regenerator can return about 3,000° more. A most useful and about 4,000° in the turnace, to whom the regenerator can return about 5,000° more. A most useful and powerful form of gas-furnace has been invented by Mr. George Gore, who thus describes it:—A is a cylinder of fire-clay about nine inches high and six inches diameter, open at both ends, with a bole in its side near the bottom, to lead into the chimney; it is covered by a morable plate of fire-clay (B), with a hole in the centre for introduction or removal of the crucible, &c.; this hole is closed by a perforated plug of clay (C), for access to the contents of the crucible, or clay (0), for access to the contents of the crumble, and that again is closed by another clay stopper (D). E is a chimney of sheet iron, about five or six feet high, kept upright by a ring of iron (F) attached to the top of the furnace. The fire-clay cylinder is inclosed in a sheet-iron casing, with a bottom of iron, to which are fixed three igon legs (G). An iron tube

#### Gas-Furnace

(H), with a prolongation (I), supports, by means of the screw J, the burner K, and its tube L, which is open at both ends. Gas is supplied to the burner by means of the tap M, which has a small index (N) attached to it for assistance in adjusting the gas. In-side the larger cylinder is another fire-olay cylinder, or cupols (O), with open ends, and with three projec-

GORE'S GAS-FURNACE.

tions of fire-clay (P) for supporting the crucible (Q). It is kept steady by means of three fire-clay marbles (R). The gas-burner is a thin metal cylinder deeply (M). The gas-burner is a tain metal cylinder deeply corrugated at its upper end, with the corrugations diminishing to nothing at its lower end. The action of this furnace is as follows. Gas is admitted to the open tube L by the tap M; it there mixes with air to form a nearly explosive mixture, which ascends through the burner and burns in the clay oplinder O, through the burner and what is the consider of the air necessary to complete combustion through the tube H to the outer surface of the flame by means of the spaces between the corrugations. The flame and products between the corregations. The name and products of combustion pass up through the cylinder O, and then downwards outside it to the chimney, the focus of greatest heat being at Q. It is important in using this furnace that the burner should be placed quite in the centre of the bottom of the tube O, also that a cracible of not too large, or not too small, dimensions the colorion of the tube O. The most suitable way of supporting erecible of not too large, or not too small, dimensions be selected. The most suitable way of supporting a smaller crucible is by placing it in a larger one that has had its upper parts broken off. If desirable, a little elsay luting may be placed round the top edge of the iron casing, to exclude air entering between it and the cylinder; also a little thin clay luting upon the part of the bottom of the furnace where the inner avoinder O rests. In lighting the furnace the place part of the bottom of the furnace where the inner ovlinder O rests. In lighting the furnace, the plugs C and D are removed, a light held inside the opening, and the gas turned on full. Should the flame blow down to the bottom of the tube L on lighting (which, however, rarely occurs, unless the furnace is already hot), the gas must be turned off and the bottom of L momentarily closed, whilst lighting the gas as before. Should the flame not burn down to the burner, but the prifice in the claysulate B. it must at Should the flame not burn down to the burner, but only burn at the orifice in the clay-plate B, it must at once be extinguished and relighted, otherwise some of the gaseous mixture will pass into the chimney unburned, and subsequently ignite and cause an explosion. A large flame now issues from the top orifice, and is white if too much gas is on, and chiefly violet or red with the proper quantity; it should now be

#### Gas-Furnace

coarsely adjusted until these appearances are presented. The annular ping C should now be inserted, which will compel it to pass downwands towards the chimney, and as soon as the small remaining fisme now issuing disappears, or nearly disappears, as it will in a few seconds, the small stopper D should also be inserted. In lieu of this, the large fisme may be defeated against the chimner by warms of a pince of flected against the chimney by means of a piece of aheet iron, until it withdraws inward, as before mentioned; the two plugs may then be re-inserted. The gas-tap may now be partly adjusted. The crucible should be placed in the furnace after the act of lighting the gas, but not impediately after it he formance. ing the gas, but not immediately after if the furnace is cold, or explosions may occur by unburned gaseous mixture passing the crucible into the chimney, and igniting afterwards. After about five minutes the gas should be slowly adjusted, until a sound is heard in-side like a series of small explosions. This sound is sometimes not very distinct, especially at high tem-peratures, and therefore requires a little experience peratures, and therefore requires a little experience in the use of the furnace in order to be detected. It is, however, a chief guide in determining the proper amount of gas, and should therefore be carefully studied. To, assist in adjusting the gas, it will be found very useful to place a small piece of locking-glass beneath the tube L, and to adjust the gas tap until the flame between the burner and the crucible appears wholly violet or slightly white. But this test is liable to fallacy if employed when the gas is just lighted, because the coldness of the parts makes the flame much whiter than it otherwise would makes the flame much whiter than it otherwise would haves the name muon whiter than it otherwise would be. It is also fallacious, the flame appearing whiter than it really is when the crucible is very hot. It is, however, of great use at intermediate temperatures. A rough deposit on the outer edge of the crucible indicates an excess of gas. The deposit is carbon. Less gas is required with a crucible in the furnace than Less gas is required with a crucible in the furnace than without one; also less is required when the small hole at the top of the furnace is open, than when it is closed; also less is required when the furnace is cold than after it has been lighted some time, because the draught gradually increases and draws in more air. After having accurately adjusted the gas, no further attention to the furnace is requisite. Having once found the proper adjustment of gas under certain known conditions, it is well to notice the position of the indexpointer N, in order to be able at once to adjust it to about the right point upon ether occasions. Under ordinary circumstances, during daylight, I have found it best to set the gas nearly full on at first, and fully on at five minutes afterwards, when the draught has on at five minutes afterwards, when the draught ha on at five minutes afterwards, when the draught has become more powerful; but during twilight, when the supply from the gas-works is more free, I have set the index-pointer at the numbers 2½ or S. The gas should be supplied by a pipe of not less than \$\frac{1}{2}\$-inch bore, with a main pipe of half an inch; but all dependation that the pressure of gas at the particular locality, which is very variable. The consumption of gas varies from thirty to forty cubic feet per hour, the value of which is about twopence. The top of the chimney should be placed in a nesition where the prochimney should be placed in a position where the pro-ducts of combustion can pass freely away. If it is placed in an opening or pipe leading to another chimplaced in an opening or pipe testing to shother ohim-ney, care must be taken not to have the draught too powerful, otherwise the heat will be drawn more into the chimney, and the supply of gas in the daytime may be found rather deficient. The furnace will act may be found rather deficient. The furnace will act satisfactorily, though less powerfully, with the chimney standing in an open room, without any special outlet for the products of combustion, provided the full height (6 feet) of chimney is employed. Under other circumstances, I have generally used a chimney 44 or 5 feet high. This furnace will produce what is generally called a "white heat." It will readily melt half a pound of copper or six ounces of cast from. Is will melt as large a quantity of those substances as the largest-sized crucible that can be introduced into it will contain, nufficient space being preserved around it will contain, nufficient space being preserved around the largest-sized orucible that can be introduced into will contain, sufficient space being preserved around the crucible for draught. It requires from twenty to thirty minutes to acquire its highest temperature, and then the entrance part of the chimney exhibits a faist red heat in daylight. If it exhibits much more than this, the draught is too powerful, and, if less, there is not sufficient gas. When the small hole D is open, some air is drawn in that way, and less air passes up

## Gaslight in Houses

Gases, Liquefaction of

with the gas through the tube. But the cold air does not much diminish the temperature of the crucible, because it combines with the excess of gas now passing over the edge of the inner cylinder; it, however, renders the flame round the crucible white by deficiency of air, and this should be partly corrected by lessening the gas. An excess of either gas or air renders the surface of the melted copper dull. When it is desirable to perfectly avoid contact of air with the fased substance during manipulation, a narrow crucible should be employed, and a thin and narrow ring of fire-clay should be placed upon the top of the tube O, to contract its opening; the flame then closes completely over the top of the crucible, and prevents access of air. A proper adjustment of gas, together with the exclusion of air in this manner, enables a perfectly bright surface of melted copper, or even tin, to be continuously maintained, from which the images of parts above are clearly reflected. The claying may be withdrawn by lifting the plate B. A less perfect exclusion of air may be obtained by employing a narrow crucible placed rather low. A small iron dish should be placed beneath the tube L, to receive any melted metal.—For a description of many ingenious forms of furnaces, the reader is referred to Ure's Dictionary of Arts, Manufactures, and Mines; and to Watta's Dictionary of Mechanics the following article relative to the consumption of gas inhouses:—'Serious objections stand in the way of the introduction of gasight into private dwellings, unless some means can be adopted for removing the products of combustion. For every cubical foot of gas burnt rather more than a crubic foot of carbonic acid is produced. A pound

a orbic foot of carbonic acid is produced. A pound of coal gas contains on an average 0'3 of hydrogen and 0'7 of carbon; it produces when burnt 2.7 of water and 2.56 of carbonic acid gas; consumes 4.26 cubic feet of oxygen, which is the quantity contained in 193 cubic feet of air. It is thus obvious that the air of a close chamber must soon be vitiated by the combustion of gas, and that the consequences of breathing an atmosphere impregnated with a large proportion of carbonic acid must, consequently, soon be felt by the inhabitants. The water evolved at the same time in the state of steam is found to be seldom same time in the state of steam is found to be seldom free from sulphurous and sulphuric acids, derived from impurities in the gas; and this condensing upon the furniture, books, goods in shops, &c., very soon damages them in a very perceptible manner. The large quantity of water evolved from the Bude burner in lighthouses, condensing on the glass windows, and materially impeding the passage of the light, attracted the attention of Mr. Faraday to the invention of some means for effectually removing the noxious products of combustion. After several more or less successful trials, he made use of a method which was a beautiful of combustion. After several more or less successuriarials, he made use of a method which was a beautiful adaptation of the principle of a descending draught to a lamp-burner. The invention sensisted of an ordinary Argand burner, with a common straight chimney; the glass-holder, however, was so constructed, as to sustain not merely the chimney, but an outer oplinder of glass also; the glass-holder was provided with an aperture, connected by a mouthpiece with a metal tube, which served as a ventilating-flue, and which, after passing horizontally to the centre of the chandelier, ascends to produce draught and carry off the products of combustion into the chimney or the open air. The outer cylinder was closed at the top by a plase of mics, or, still better, by two plates of mics, one resting on the top of the glass, and the other dropping a short way into it. They were connected together by a metal screw and nut, which also kept which had no opening, except at the bottom, for the admission of air to the burner. It is stated that the intense heat produced by the hot current of for the admission of air to the burner. It is stated that the intense heat produced by the hot current of air traversing the space between the two glass cylinders eases the glass to become more excless opaque, and thus obstrants the passage of the light. To avoid this objection, the same principle has been applied in a still more elegant and perfect manner, to a ventilisting form of gas-burner, in which the air for the flame descends through apertures in the top of a glass 914

cylinder, being afterwards carried off through a flue, when it has supplied oxygen to the flame and become vitiated. Ventilating burners of this kind not only prevent the diffusion of the products of combustion through the apartment in which they are erected, but, with the hot current of gas ascending through the metal tube, a large quantity of air from the room is also carried away, and thus a proper circulation established." Among the many commendable forms of gas-burners which have been brought under the notice of the public, the Whinfield lucent burner, in which the Liverpool button is applied to an Argand gas-burner, is among the best and most ingeniously constructed. The peculiar form of the chimney causes an external current of air to impinge at a certain angle upon the flame, producing the same affect as the metallic cone in the solar lamp. A basket of wire gauze is fitted into the crutch of the burner, which moderates the supply of air from below, and prevents the flickering caused by sudden draughts, by fixing the chimney to a circular ring, which acrews up and down upon the triangular support. Lowe, in his improvement upon this form of burner, alters the direction of the external current caused by the contraction of the chimney, and by converting the button into a screw, its height can also be altered and the internal current regulated.

GASES, LIQUEFACTION OF (in Chem.).—Many gases which are aeriform at ordinary pressures and temperatures, may be condensed into liquids, and even solids, by the combined action of pressure and cold. The experiments of Faraday in this direction have shown that the difference between gases and vapours is only one of degree, gaseous carbonic acid bearing the same relation to the solid gas that steam does to ice. The apparatus employed by this philosopher is extremely simple. It consists of a very strong tube closed at both ends and bent at an angle. One end contains the substances necessary for the production of the gas, while the other is immersed in a freezing mixture. Some of the gases are liquefied with greater facility than others; thus a mere reduction of temperature to 0° is sufficient to reduce sulphurous acid to a liquid state. The gases which have been solidified, up to the present time, are the following:—

Temp. of Solidification. at 32° F. Sulphurous acid...... -105° 1:59 atmos Cyanogen — 30° Hydriodic acid — 60° 2.37 ... 3.97 Ammonia.... -103° Sulphuretted hydrogen ... -122° 4.4 32. Protoxide of nitrogen ..... -150° \*\* 38.5 Carbonic acid..... - 70° \*\* Buchlorine ...... - 75° Hydrobromic scid ..... - 124° Fluoride of silicon ...... -220°

It will be observed from the — mark placed before the figures given above, that below 0° is meant. The following have only liquefied, having as yet resisted all attempts at solidification by combined pressure and cold:—

Chlorine,
Arsenetted hydrogen,
Phosphuretted hydrogen,
Hydrochloric soid.

The lowering of the temperature that takes place in the surrounding stmosphere during the passage of a gas from the liquid to the gaseous state, by the abstraction of an amount of heat sufficient for it to renter its aëriform condition, has been taken advantage of by M. Carré, an ingenious French mechanician, in his ice-machine. It consists simply of two strong iron ressels connected by a tabe, one of which contains strong liquor ammonias. Heat is applied to the liquor ammonias by means of a lamp or furnace. The ammonia immediately rises in vapour, and becomes condensed in a liquid form in the vessel at the other end. The lamp is removed, and the vessel containing the liquefied gas is plunged in another vessel containing the substance to be frozen. The liquid gas gradually reassumes the gaseous form, abstracting from the

#### Gas Meter

liquid to be frozen a sufficient amount of heat to com vert it into ice. The apparatus is perpetual, the only condition necessary for its use being its perfect airtightness

Ightness.

Gas Merru (Gr. metron, a measure), an instrument through which coal-gas is made to pass, in order to ascertain the quantity consumed in a particular time or place. They are divided into two classes,—wet and dry gas meters. The former usually consists of a cylindrical case, within which is snother cylinder, shut at both ends, and movable round an axis, divided into four parts. This vessel is so far filled with water, that the pine which conveys the gas into it just rises above it. plarts. This vessel is so a find it just rises above it.

As the gas enters, it causes the cylinder to move on its
axis, and as each volume of gas passes through, the
wheel of the axis, which works in other toothed wheels, registers, by means of an index, the number of cubic feet passing through the meter in a given time. The dry meter is an improvement on the wet, as the latter admits of fraudulent means being employed by The water in the wet meter is also the consumer. liable to get frozen in winter. Dry gas meters are made in various forms; one of the most simple and accurate is that of Defries. It is similar to that of Messrs. Croll & Richards, and both contrivances depend on causing the gas to fill expansible chambers of definite relationships of the alternate expansion and contraction of

causing the gas to fill expansible chambers of definite volume, the alternate expansion and contraction of which are registered by clock-work. Of late years dry gas meters have come tate extensive use in London. GASOMETER. (See Gas MANUFACTURE.)
GASTEROFODA, giz-ter-op'-o-di (Gr. gaster, stomach; poss, foot), a class of molluscous animals, whose means of locomotion consist of a fleshy disc or foot situated under the abdomen. They are both terrestrial and anustic, and maked and possessed of a shell. Of the aquatic, and naked and possessed of a shell. Of the

aquatic, and naked and possessed of a shell. Of the naked Gasteropoda the common slug will serve as an example. Among the terrestrial of the genus is found the snail; and among the aquatic, the whelk, winkle, &c. GASTRIC JUCK, gids-trik (from gaster, the stomach, is the name given to the digestive fluid contained in the stomach, and which is secreted by the gastric glands on the introduction of food or other foreign substance. It is a clear transparent fluid, inodorous, a little saltish, and very perceptibly acid. Its most singular component is a peculiar organic substance called pepsine, to which its special properties are chiefly owing. The use of the gastric juice is to dissolve the various kinds of food in the stomach, reducing the albuminous and gelatinous portions of it to a state fit for absorption into the system. It has also an antiseptic property, as it suspends putrefaction and restores the freshness of tainted meat.

GASTRITTS, gids-tri-tim (lat.), in Surg., denotes in-

restores the freshness of tainted meat.

Gastaffie, gda-tri'-tis (Lat.), in Surg., denotes inflammation of the stomach. It is known by pain in the
epigastric region, increased when anything is taken
into the stomach, vomiting, and hiccough; the pulse
small and hard; and general prostration of strength,
attended by fever and anxiety. It is produced by
poisons of various kinds taken into the stomach, as
arsenic or corrosive sublimate; by food of an improper
nature; by draughts of any cold liquid when the body
is much heated. It is a rapid and very dangerous
disease, and requires prompt measures to be adopted.
The means employed are copious and repeated general The means employed are copious and repeated general The means employed are comous and repeate general bleedings; the application of leeches to the epigastrium, followed by fomentations or the hot bath, after which a large blister may be applied. When sorid substances have been taken, mucilaginous drinks may be of use to aid their evacuation and protect the stomach, and when it arises from active poisons, the

stomach-pump may require to be used. GASTONERIUS, gis-tro-ne'-me-us (Gr. gaster, the sto-mach; kneme, the leg), is the name given to the belly or calf of the leg; and is also applied to two of the mucales of that part. The gastronemius externus arises by two distinct heads from the inner and outer condyles of the os femoris, which units a little below the oyies of the stemoris, which these states estowers in joint; and below it unites with the gastronemius internus, to form the tendo Achillis. The gastronemius internus, called also the soless, is situate immediately under the above, and rises by two heads from the posterior part of the head of the fibula and the upper and posterior part of the tibia. The nee of both these muscles is the same; namely, to raise the heal and extend the foot.

extend the foot.

### Guaging

GASTRONOUY, gds-iron'-o-me (gaster, the stomach, and nome, law), may be strictly defined to be the science of eating and drinking or, in short, the physiology of taste. In the classics we read of many names rendered celebrated by the fact of their being names rendered celebrated by the fact of their being excessive gourmands, or worshippers of good living, as Lucullus and Apicius; and, indeed, one Archestralus, of Syracuse, a contemporary of Pericles, has handed down to posterity a poem on the art of gastronomy, which has been translated by Ennius. This author is the first who appears to have treated on the subject, as M. Brillat-Savarin, who, in his Physiologic du Goût, has exhausted every argument which could be used in its favour, is the last. Gastronomy must not be confounded with cookery, from which it is wholly distinct. wholly distinct.

GASTROTOMY, gits-trot'-o-me (Gr. gaster, and toms, an incision), in Surg, denotes an incision into the cavity of the abdomen, an operation sometimes resorted to in desperate osses; as where, in consequence of a rupture of the uterus, the child escapes into the peritoneal

GATEWAY, gait'-way (Ang.-Sax.). — The gateways, or gatehouses, of the middle ages were most imposing structures; but, in the present day, this branch of architecture seems to have become neglected, or has architecture seems to have become neglected, or has fallen into disuse. They used to be erocted over the principal entrances of the precincts of religious establishments, colleges, and other buildings, and sometimes also in the courts of private houses, and those before castles and other fortifications. In military edifices, the entrance usually consisted of a single archway, with a charge door large another to a single archway, the entrance usually consisted of a single archway, with a strong door, large enough to admit carriages, and portculis at each end, with a vaulted ceiling pierced with holes, through which missiles might be rained down on an enemy. The sides of the gateway were generally flanked with large projecting towers pierced with loopholes, and the upper part terminated in a series of machicolations and a battlemented parapet. In civil edifices, the gateway admitted of much greater diversity of form. Sometimes it was formed of a single square tower, with the front ornamented; or it was extended to a considerable breadth, as at Battle Abbey, in Sussex. The gateways of religious houses had frequently a chapel attached to them. Examples of them may be seen in most of our old cathedral towns; as at Oxford, Canterbury, &c.—

them. Examples of them may be seen in most of our cold cathedral towns; as at Oxford, Canterbury, &c.—Ref. Glossary of Architecture.

GAUGE, gaipe (from. Fr. jauger, to gauge), an instrument or apparatus used for measuring the state of a phenomenon. Thus the gauge of an air-pump is a barometer, connected with the interior of the receiver, which shows the degree to which the air is rarefled. which shows the acgree to which the air is refrect. The wind-gauge, or automometer, is used in order to measure the force or velocity of the wind; and the water-gauge, or hydrometer, for determining the specific gravity of liquids, and thence the strength of spirituous liquors. (See ANEXOMERER, HYDROMERER.) In various and the property of the second o liquors. (See ANEMOMETER, HYDROMETER.) In various trades and manufactures, gauges of different kinds are employed; such as those used for measuring wires and sheet metals. These are generally thick plates of steel, of varied size and form, round, and near the edges of which, are drilled various holes, with notches sawed from the edge into every hole. Small parallel plates of hardened and tempered steel, called "drifts," are then driven into the notches in order to smooth the of hardened and tempered steel, called "drifts," are then driven into the notches, in order to smooth the sides and make them uniform. The Birmingham gauge for iron wire, and sheet iron and steel, differs from the gauge used for sheet brass, gold, silver, &c.; and both these differ from the Lancashire gauge for round steel wire. Many other gauges are used in par-ticular trades; such as the rod-iron gauge, the nail-rod gauge, the button-makers' gauge, &c.; others are used in watch-work; gum-makers also use a gauge for the bores of guns and rifles. Garange, and into. the method of determining by

bores of guns and rifles.

Gaveira, gai'-jing, the method of determining by actual measurement the number of gallons contained in ressels intended to hold goods; chiefly casks, barrels, vats, &c. The principal use of gauging is in the collection of the revenue, in which it is necessary to measure the bulk of vessels, without disturbing their contents. The principles of gauging are those which are furnished in geometry for the measurement of solids. As, however, the men who are engaged either in compares or by the excise, for the purpose of gauging, are not likely,

in general, to be acquainted with the principles upon which the art depends, a set of technical rules and appropriate instruments have been contrived, by which the art can be practised by any one of moderate intelligence. The instrument usually employed is the gauging rod, or diagonal rod, by which the contents of a cask are inferred from its diagonal length, measured from the bung-hole to the extremity of the opposite stave at the head. A scale of inches, for taking the transaure of the diagonal, is described on one face of a source rule, usually about four feet lone; and on the square rule, usually about four feet long; and on the opposite face is a scale expressing the corresponding contents of the cask in gallons. Although this method, obviously, can only give approximate results, yet, by using larger sliding-rules for calculation, and the aid of habit, derived from experience, it is possible to attain habit, derived from experience, it is possible to attain considerable accuracy in measuring the contents of casks, which do not depart much from a given standard of form.

of form.

GAULT, gawit, in Geol., the term which is applied to a series of dark blue marls or calcareous clays, which occur between the upper and lower greensand of the Chalk formation. It can be examined very well at Folkestone and Cambridge. The marine shells contained in it are often beautifully preserved, having been well packed and protected from atmospheric influences. The word "gault" is a provincial term for the clay itself, which is much used for brickmaking.

When decomposed it forms a very fartile soil and is When decomposed, it forms a very fertile soil, and is

the main repository of the phosphatic nodules which are now so highly prized by the agriculturist.

GAYELEIND, gdv'-el-k:nd, in Eug. Law, is a species of tenure of lands, which is supposed to have been, previous to the Norman conquest, the general custom of the realm, and which is found to this day in Kent, in consequence, it is said, of the success that attended the struggles of the Kentish men to preserve their ancient liberties. The origin of the term is much dis-puted. According to Coke, it is formed from "Gave puted. According to Coke, it is formed from "Gave all kinds; for this custom giveth to all the sons alike;" but the more generally received opinion is that it is de-rived from the Saxon word gavel, or gavel, signifying rent, or a customary performance of husbandry service; and hence the land which yielded this kind of service, as rent, or a customary performance of husbandry service; and hence the land which yielded this kind of service, as opposed to knight-service, was called garelkind. The chief distinguishing features of this kind of tenure are—(1) that the lands descend not to the eldest, youngest, or any one son only, but to all the sons together; but the issue of a deceased son inherits his sharp, whether male or female; (2) that the tenant is of sufficient age to aliene his estate by feofiment at the age of fifteen; (3) that the estate does not escheat in case of an attainder and execution, their maxim being "the father to the bough and the son to the plough." In most places, the tenant had a power of devising lands by will, before the statute authorizing the devise of lands generally was made. In default of sons, the land descends in equal shares to daughters; in default of lineal heirs, the land goes to the brothers of the last holder; and in default of brothers, to their respective issue. The husband is tenant by courtesy of a moiety of his wife's lands, whether there be issue or not, so long as he remains unmarried; and a wife is endowed of a moiety of the lands of which her husband died seized, during her chaste widowhood. Though

row, and pointed; eyes large, mild, and black. The size of the gazelle about equals that of the roebuck; but the legs of the former are considerably longer, and the entire form more graceful. The face and checks are reddish fawn-colour, with a dark stripe down the nose; on each side of the face, passing over the eyes, from the horns down to the nose, there is a broad white stripe, and beneath this, from the anterior canthus of the eye, a narrower dark stripe parallel to it and separating it from the fawn-colour of the check. The remainder of the body is dark fawn above and it and separating it from the fawn-colour of the cheek. The remainder of the body is dark fawn above and white beneath, the latter colour being separated by a broad brown band along the flanks. The knees are furnished with bruahes of dark hair, and the ears are filled internally with long white hair. It lives in large troops, and when pursued by the hunter, flees at great speed for some distance, then stands still to gaze on him, then bounds off again. When brought to bay, these animals defend themselves with courage and obstinacy, meeting in a close circle, with the females and fawns in the centre, and presenting their horns at all points to their enemies.

GAZETTE, gä-zet' (Ital. gazzetta), in Lit., is the name of certain newspapers in this country and on the con-tinent. It is said to be taken from gazzetta, the name of a Venetian coin worth somewhat less than a farof a Venetian coin worth somewhat less than a farthing, and which was the price of the earliest new-paper published in Venice (1563). According to others, it is derived from gaza, a treasure, or gazza, a magpic. The first fazette published in France (under that name) appeared in 1631, the first in England in 1685. The first fourteen numbers of the London Guzette were published at Oxford, the court being then resident there on account of the plague in London. It is published under suthority of the government. then resident there on account of the pague in London. It is published under authority of the government, and appears regularly twice a week, on Tuesdays and Fridays. It contains all proclamations, orders of council, and an account of all matters done by the queen in her official capacity; promotions and appointments to commissions in the army and nary; the appointment of ambassadors, consuls, and other civil officers of the higher ranks; also various matters connected with legal proceedings, notices of bankruptcies, insolvencies and sequestrations, dissolution of partnerships, &c. Notices of intended applications to parliament for private acts, relating to railways, canals, &c., require to be published in the Gazetts.

GAZETTERE, giz-et-teer', is, in other words, a dictionary of geography, a work giving an account of the different places on the face of the earth, under their particular names, in alphabetical order. The first work of this kind with which we are acquainted is that of Stephen of Byzantium, who lived about the beginning of the the content of the stands is the "Dictionarium Historico-Geographicum" (Geneva, 1868) we Charles Gischares with efficiency we W Lloyd. don. It is published under authority of the govern-

of fifteen; (3) that the estate does not escheat in case of an attainder and execution, their maxim being "the father to the bough and the son to the plough." In most places, the tenant had a power of devising lands by will, before the statute authorizing the devise of land generally was made. In default of sons, the land generally was made. In default of sons, the land descends in equal shares to daughters; in default of lineal heirs, the land goes to the brothers of the last holder; and in default of brothers, to their respective issue. The husband is tenant by courtesy of a molety of his wife's lands, whether there be issue or not, so long as he remains unmarried; and a wife is endowed of a moiety of the lands of which her husband died seized, during her chaste widowhood. Though the lands of Kent have now, for the most part, been disgouetted by particular statutes, yet the presumption is still in favour of this species of tenure until the contrary be shown—Ref. Robinson's Treatise of Gazekkind.

Gazor, gd-set (Fr. gavotte), a dance consisting of two light lively strains in common time, each being played twice. The first usually contains four or eight hars, and the second eight or twelve, and sometimes more. The first strain should close in the dominant or fifth of the key; for if it has its termination in the tonic or key-note, it is not a gavot, but a rondeau.

Gazelle, gd-zet/ (Fr.), (Antilope Dorcas, Pallas), one of the most beautiful and graceful of the antiloperation of the most beautiful and graceful of the antiloperation of the most beautiful and graceful of the antiloperation of the most beautiful and graceful of the antiloperation of the world, published by Fullation & Co. (7 vols. etc.) and finally forwards. The horns of the adult male rise nearly perpendicularly above the orbits, are black, almost cylindrical, bending at first gently back, and single Pronouncing Gazetteer of the United States of the United States are Lippincott's "Complète Pronouncing Gazetteer of the United States" (Philadelphia,

the World" (Philadelphia, 1856), and Harper's "Statistical Gazetter of the World."—Of other countries may be mentioned Möller's "Geographisch-Statistisches Lexikon" (1847); Ritter's "Geographisch-Statistisches Lexikon" (1847); Ritter's "Geographisch-Statistisches Lexikon" (4th ed. Leipsio, 1855); Hoffmann's "Encyclopsedie der Erd., Volker- und Staatenkunde" (Leipsio, 1855, et seg.); Krämer's "Geographisch Woordenboek" (Gouda, 1853); Castro's "Gran Dizionario Geografico" (Milan, 1855); "Dictionnaire Géographique universel," par une Société de Géographes (10 vols. Paris, 1822-33); Dictionnaire Géographique universel," par une Société de Géographes (13 vols. Brussels, 1839); Bescherelle's "Grand Dictionnaire de Géographic universelle, ancienne et moderne" (4 vols. Paris, 1856-7).—One of the most extensive and valuable Gazetteers of particular countries is the "Diccionario Geografico-Estadistico-Historico de España," by Pascual Madoz (Madrid, 1847-8), in 16 volumes.—A valuable dictionary of ancient geography is that recently published by Dr. William Smith. Nor under this head must we neglect to mention the geographical section of the "English Cyclopedis."

GEBENNA, ge-ken'-nd, is the Greek form of the Hebrew Ge-kinnow, the valley of Hinnom, and is used in Scripture to signify hell, or the place of eternal punishment. The valley of Hinnom was a narrow valley or gorge in the neighbourhood of Jerusalem, where the sewage and filth of that city was carried, and where perpetual circs were kept up to destroy the noxious matter. In later times et became a favourite

and where perpetual dires were kept up to destroy the noxious matter. In later times it became a favourite place for the celebration of idolatrous rites, and at a part of it, named Tophet, it is recorded that the abominable practice of infant sacrifice was exercised.—Hence the terms Gehenna and Tophet came to be synonymous

GELATINE, or GELATIN, jel'-ă-teen, jel'-ă-tin, an azo-tised principle, which has hitherto been obtained from animal tissues only. Bones, skins, flesh, and other parts of the animal, yield gelatine when boiled, but it does not appear to exist in a free state in any of these substances. Gelatine softens and swells in cold water, but does not dissolve until the liquid is heated. When the solution cools, it solidiles to a firm jelly; hence its name. It is insoluble in alcohol and ether, and may be precipitated from its aqueous solution by the former. With tannic acid it forms an insoluble compound of a buff colour, which is the basis of leather. It is also abundantly precipitated by solutions of corrosive sub-limate and bichloride of platinum. By continued boiling, gelatine is converted into metagelatine, which does not possess the property of gelatinizing as the liquid cools. The term is derived from the Spanish

figure coust. The verm is derived from the Spenisses gelating, from the Lat. gelo, I freeze.

Gelatine and Chue, in Manuf.—As gelatine is only glue in a greater state of purity, it will be as well to onsider the two substances under one heading. Glue

consider the two substances under one heading. Glue is obtained from the parings and refuse trimmings of or and other hides, which generally contain from 40 to 50 per cent. of glue. They are steeped for several days in lime-water, to remove the hair and blood, and then drained and dried in a current of air, in order that the lime may absorb carbonic scid from the atmothat the lime may absorb carbonic acid from the atmosphere. They are then boiled down in a copper containing a perforated false bottom, fresh clippings being added until the liquor gelatinizes in cooling. It is then kept at a gentle heat until the impurities have settled, and it is transferred to wooden boxes, or coolers, in which it is relativistic. and it is transcerred to wooden acceptance which it gelatinises. The blocks so formed are cut into cakes while soft, and dried in nettings, the threads of which leave the well-known cross-bar markings. The of which leave the well-known cross-bar markings. The drying is the most particular part of the process, a sudden rise of temperature will destroy the whole batch, by partially dissolving it; or a frost will split the cakes into fragments. Gelatine is simply glue which has been dissolved in a large quantity of water, and allowed to settle until colourless. Size is a less-tona-

thus forming ten times more jelly than a like weight of the best animal gelatine. Jelligs made from this sea-weed are much employed for food in Japan.

GRLOSE. (See GELIDIUM.)

GEMINI, jem'-e-ni (Lat., the twins), in Astron., the third constellation, or sign of the zodiac. The title is referred by the Greeks, not only to the fable of Castor and Pollux, but also to those of Hercules and Apollo, Triptolemus and Ission, Amphion and Zethus, &c. The name of the Twins is given to the constellation from two remarkable stars of the first and second magnitude, to which the names of Castor (or a Gemimagnitude, to which the names of Castor (or a Geminorum) and Pollux (or \( \beta \) Geminorum) are given. These two stars, when once known, can be easily recognized on account of their proximity. By drawing a straight line through the belt of Orion and the two bright stars, the line of which cuts through the belt, the Gemini may be easily found; for the straight line, when lengthened upwards, will pass very near the two stars. They are also about halfway between Regulus and Aldebarau; and when Orion and the Great Bear are seen together, Capella on one side and Castor and Pollux on the other, form the most conspicuous boundary-marks of the space between.

Gemore, ge-mote' (Ang.-Sax.), was the name of certain motes or courts held at certain times among the Angle-Osaxons; as the shire-gemote, or county

the Anglo-Saxons; as the shire-gemote, or county court, which met twice a year; the burg-gemote, which met thrice; and the hundred-gemote, which assembled every month. The witens-gemote was the great national council of the Anglo-Saxon kings.

met turice; and the innered-gemote, which assembled national council of the Anglo-Saxon kings.

GEMS, jems (Lat. gemma, a precious stone), a term commonly applied to all precious stones, and particularly to those which are used in jewellery. They are usually cut by the lapidary and set in gold, or carved as signets for rings, &c. The chief objects desired in minerals of this kind are brilliant lustre, perfect transparency, and richness of hue. Amongst those gems which are cut, the diamond holds the first place for brilliancy of lustre, or water, as it is termed. (See Diamond.) The oriental ruby is next in value, when of considerable size, of perfect transparency and rich colour. It is chiefly found in the Capellan mountains, near Syrian, in the kingdom of Ava. The sapphire, which varies from a dark rich blue to a pale and almost colourless tings of the same hue, holds the next place. It is found in comparatively large masses in Ava and Ceylon. The emerald, with its peculiar rich green colour, is held in high estimation by Eastern monarchs. The aquamarine is a pale blue variety of the globe; and for the striking changes which it undergoes when it is exposed to heat, and the fine colours which it naturally displays, is peculiarly suited to the lapidary's art. Garnets of very rich colour are obtained in Ceylon and Greenland. Chrysolites of a pale green colour come from Constantinople; deep red hyscinths from Ceylon; and tournalines of various hues from most parts of the world. Other stones also come under the designation of gems. Among these may be mentioned the opal, and many varieties of quartz, such as the amethyst, sarde, onyx, cat's-eye, and agate. The art of engraving on gems is very old, although it has been doubted whether the ancients understood the method of cutting the diamond, or sculpturing the emerald and topaz. The Eastern nations are still unacquainted with the proper mode of outting and polishing the diamond. In the year 1500, an Italian, named Ambross Caradopo, engraved the portrait of a father o named Ambrose Caradopo, engraved the portrait of a father of the church on a diamond, which he sold to Pope Julius II., a great patron of the arts, for £5,500, a large sum for that period. His example was followed by other artists, diamond-dust being employed in reducing the gem. The minerals most used for purposes of engraving, both in modern and ancient times, are not mystel or opening of various column and decious kind of glue, made from parchment parings and the thinner pieces of skins.

General Stromer Strome St

### Gendarmes

the decline of their country, the Greeks became much more eminent for their gems than any other nation of antiquity. They practised seal-engraving at an early period, but apparently not upon stones. Many cele-brated names of engravers before the era of Alexander brated names of engravers before the era of Alexander have been handed down. Among others, that of Theodore of Samos, who engraved a lyre on a celebrated emerald belonging to king Polyoretes 750 years before Christ, which the owner, to mortify himself, threw into the sea. Between the period of Alexander and the Augustan age, the chief gem-engravers were Admone, Apollonides, Polyetetes, who was also a sculptor, and Tryphon. The taste for engraving on precious stones was still preserved by both Greeks and Romans during the earlier part of the dark ages. With the introduction of Christianity, the art languished, and after the 7th century it almost entirely disappeared, and remained in obscurity till the 15th century, when it was revived by the Italians. From this tury, when it was revived by the Italians. From this period, engraving on gems fluctuated greatly, and it was some time before the art was fully re-established. Modern gems are considered inferior to those of aucient times; and hence many attempts have been made to substitute fictitious gems for those which are real. These are produced in three different ways;—either by attempting to improve a precious stone, or by producing an absolute counterfeit of it, or by inscribing the name of an ancient engraver on a production of modern origin. Independently, however, of these methods of producing counterfeit gems, the ancients were acquainted with several expedients for making nrtificial gems, and chemists in all ages have turned their attention to this branch of art. In modern times, Mitscherlich, Brothier, Gauden, and others, have suc ceeded in producing artificial rubies, corundum, blue and red spinelle, garnet, and emeraid, by crystallizing mixtures containing their component parts at exceedingly high temperature. The artificial gems produced were found to possess all the properties of the real stones bether produced was to be about the red to th

stones, both in colour, hardness, and crystalline form. GENDARMES, zhau(g)-darm (Fr., from gens d'armes, mon-at-arms), is the name of a body of military police in France, comprising both infantry and cavalry. In the 15th and 16th centuries, the gendarmes constituted the most distinguished cavalry corps in the French army. Afterwards, in 1669, the name was transferred to a squadron of the royal household troops, who cone royal household troops, who constituted a kind of body-guard of the king. In 1791 this corps was abolished, and the name given to a body of police. It consists principally of soldiers taken from the army generally on account of intelligence and good the army generally on account of intelligence and good behaviour, and it is regarded as a kind of promotion, as they have better pay, and enjoy greater liberty. The corps still constitutes a part of the army, and is liable, in case of necessity, to be sent on active ser-vice. They have the character of being well-behaved and trustworthy men, and are frequently intrusted by government with the execution of matters of import-

ance and delicacy. They amount to about 25,000 men. GERDER, jen'-der (Fr. gendre, from Lat. genus, race, kind), in Gram., is the distinction of nouns according to sex. Nouns denoting the male sex are said to be masculine; those denoting the female sex, feminine; and those which denote neither male nor female are and also winds unon denote neutrer male nor female are said to be neuter (Lat. neutrins generis), of neither gender; and hence grammarians have come, somewhat incorrectly, to speak of three genders. There can, properly speaking, be but two genders, the maculine and the feminine, as the sexual distinction is the basis upon which this doctrine is built. There are many animals, however, of which it is difficult, or useless, to determine the sex; and there are also many things which cannot be so distinguished at all. These are which cannot be so distinguished at all. These are generally regarded as belonging to what is termed the nester genter. There are, however, certain ideas, as magnitude, strength, vigour, &c., which are considered as characteristic of males; while gentleness, timidity, submission, &c., are regarded as properties of females, which, when they come to be associated with a neuter noun, raises it to the masculine or feminine: thus we speak of the sun as ks, and of the moon as she. Abstract nouns and general terms are size usually regarded as feminines. The mesculine and feminine Abstract nouns and government of the meaculine and temmine regarded as feminines. The meaculine and temmine are sometimes denoted by different words, as boy, girl, horse, mare, cock, hen; sometimes by a change in the SIR

termination, as count, countess; executor, executrix; songster, songstress; and sometimes by the addition of a word, as cock-sparrow, hen-sparrow, he-gost, she-gost.—Rel. English Cyclopadia, section Arts and Sciences.

Generations, je-ne-all-o-je (Gr. genealogia, from genos, race, and logos, account), is an account or enumeration of the ancestors or relations of a particular person or family. No nation was more careful to trace and preserve its genealogies than the children of Israel. Their serve its genealogies than the children of Israel. Their snared writings contain genealogies which extend through a period of more than 3,500 years, from the creation of Adam to the captivity of Judah, and even after that time. Josephus informs us that he traced his own descent from the tribe of Levi by means of public registers, and that, however dispersed and depressed his nation were, they never neglected to have exact genealogical tables prepared from authentic documents which were kept at Jerusalem. Since, however, their destruction as a nation by the Romans, all their tables of descent seem to have been lost; and however, their destruction as a nation by the Romans, and even the Levites, who are still distinguished from the rest of the people by the exercise of special honorary religious functions, are known as such only by being acknowledged as descendants of parents who exercised the same. The inequalities of rank and right which prevailed during the middle ages made genealogical inquiries highly important; and it was then that researches of this kind assumed RM form of a science. searches of this kind assumed the form of a science, which became closely connected with heraldry (which see). Very little critical care, however, was usually employed in such cases, the chief object being to trace the origin of families into the remotest antiquity. the origin of families into the remotest antiquity. Attempts to carry this to an absurd length are frequently manifested in the earlier genealogical works. Critical genealogical studies were not begun before the 17th century. Genealogical accounts are not only interesting to porsons who feel a more or less natural curiosity about their ancestors, but are also useful to the historian, as elucidating the often complicated relations of dynasties, families, claims, and controversies of successions, &c. They are also of importance in legal cases concerning claims of inheritance; and, indeed, are indispensable in states in which the enjoyment of certain rights is made to depend upon lineage or descent. A genealogy, or lineage, is frequently represented in the form of a tree (arbor consanguintitatis), giving a distinct view of the (arbor consenguintiatis), giving a distinct view of the various branches of the family, and the degrees of descent from the common progenitor, who is generally represented in the root or stem. Genealogical tables are either descending or ascending. The former are chiefly used in historical records, presenting the descendants of a certain person in the order of procreation; the latter, in documents of nobility, serving to show the claims of any man or family to the titles of paternal and maternal ancestors. Sometimes both forms are used together. Persons descended one from another successively, form a direct line; those descended from a common progenitor, but not one from another, a collateral line. The collateral line emanother, a collateral line. The collateral line em-braces the agnates, or the kindred on the father's side, and the cognates, or kindred on the mother's side

GENERA, jen'-e-ra (Lat.), the plural of genus (which

of under their respective names.

General, jeni-s-räi (Fr. général), the name of the highest military rank, with the exception of that of field-marshal, that can be conferred on officers in the British and continental armies. It is the title given to the commander-in-chief, unless he be a field-marshal, to the commanders of armies and military districts, and to the commanders of divisions and brigades, who exercise the functions of a general with respect to the different bodies of men under their respect to the different bodies of men under their command which compose the entire army in the aggregate. In the English army, general officers are of three grades,—generals, listenant-generals, and major-generals. In the French and continental services, the rank of general of division is equivalent to that of

lieutenant-general in our service, and that of general of brigade to the rank of major-general. The command of a division in our service is always given to a mand or a division in our service is always given to a lieutenant- or major-general, but the colonel of a regi-ment may command a brigade with the temporary rank of brigadier-general. The title seems to have originated in France about 1450, when John, count of Dunois, was made lieutenant-general of the French forces, or commander-in-chief, representing the sovereign, who had delegated to his lieutenant-general the performance of the duties that would otherwise have devolved upon him as actual commander-in-chief of the armies. upon nm as actual commander-m-ener of the semies.
The title came into use in England in the reign of
Henry VIII., when the appellation of captain-general
was given to the commander-in-chief of the England.
From that period the title of general, both alone and
distinguished by various prefixes, has been preserved
in the Dettick services. in the British service.

GENERAL ASSEMBLY. (See ASSEMBLY, GENERAL.)
GENERAL BASS, in Mus., is synonymous with thorough bass. (See Bass.)
GENERAL ISSUE, in English Law, is a plea which
thwarts or denies at once the whole declaration of the plaintiff, without offering any special matter whereby to crade it; as in action for wrong, "not guilty," or for debt, "not indebted." They are called the general issue because, by importing a general and absolute denial of what is alleged in the declaration, they amount at one to an issue, by which is meant a fact affirmed on one side and denied on the other. Formerly the effect of side and denied on the other. Formerly the effect of pleading the general issue was to leave everything open,—the fact, the law, and the equity of the case; but in this way much abuse crept in, and by statute \$2.4 Will. IV. o. 42, the plea of general issue was restricted to its proper and ancient province.

Generallissing, jen-e-rill-is-e-mo (Ital.), the name sometimes given on the continent to a general officer who has the chief command of two or more armins on

who has the chief command of two or more armies, or command of general officers who act independently of each other, and are subject only to the control of the generalisaimo or commander-in-chief for the time being. grand divisions of an army, which are also under the

GENERALIZATION, jen-e-ral-i-zai'-shun (Lat. generalis

GENERALIZATION, jen-s-rai-1-221'-zan (Lat. generalis, general), the act of extending from particulars to generals; the act of making general.

GENERALIZATION, in Log., "the act of comprehending under a common name several objects, agreeing in some point which we abstract from each of them, and which that common name serves to indicate." When we constitute that the server in the that common name serves to indicate." When we con-template several objects resembling each other in some part of their nature, we can, by attending to that part alone, assign them one common name, which will ex-press or stand for them all as far as they agree; and this is what is called generalisation. Another kind of press of stand for them all salars as takey speer; and this is what is called generalisation. Another kind of generalization is when, from observing that two or more objects have certain things or properties in common, that therefore they have others also in common; as where Newton, from the fall of an apple, discovered the law of gravitation. In this process of generalizing there is involved a principle which experience does not furnish, by which we aftirm not only that all heavy bodies which have been observed gravitate, but that all heavy bodies which have been observed gravitate, but that all heavy bodies which have been observed gravitate, but that all heavy bodies which have been observed gravitate, but that all heavy bodies. Whether they have been observed or not, do so. In this there is implied a belief that there exists a certain order in nature, and that, under the same circumstances, the same substances will present the same phenomens. (See Induction, Classification.)

Generations, Alternation of, jene-orai-shauz (Lat. generatio), a term applied by Professor Steenstrup to a series of phenomens connected with the mode of reproduction of many of the lower animals. In their development from the ovum to the adult state, a large number of these beings not only pass through

In their development from the ovum to the adult state, a large number of these beings not only pass through various stages, as exemplified in the insect tribe, but also possess the power of multiplying themselves at certain periods of their growth. The animals which exhibit this peculiarity have been called "nurses," and the phenomenon has been particularly observed in the Anophalm, Entozos, Polypifers, Salps, and Vorticelle. In the translation of Professor Steenstrup's work by the Ray Society, the abstraction of generations is fully described. The mode of development by means

of "nurses," or intermediate generations, is shown to be an ordinary phenomenon in sature. "The circumstance," he observes, "of an animal giving birth to a progeny permanently dissimilar to its parent, but which itself produces a new generation, which either itself or in its offspring returns to the form of the parent animal, is a phenomenon not confined to a single class or series of animals; the vertebrate class is the only one in which it has not yet been observed. It would consequently appear that there is something intrinsio in this mode of development, and that it occurs, as it were, with a certain necessity; on which account as it were, with a certain necessity; on which account is it were, with a certain necessity; on which account it will undoubtedly soon be recognized to a greater extent and more generally." If the whole system of development by means of "nursing" generations be collected and regarded in one view, it appears, as the essential feature in this course of development, that essental leature in this course or development, that the species is not fully represented in the solitary, full-grown, fertile individuals of both sexes, nor in their development; but that to complete their repre-sentation, supplementary individuals, as it were, of one or, of several precedent generations are necessary. one of or several precedent generations are necessary. The greatest incompleteness and the highest degree of mutual dependence is to be observed in the Campanularize and similar polypes, in which the generations representing the unity of the species are very unlike each other, and in which all the individuals are found into a part of male and the conditions of the species are very unlike each other, and in which all the individuals are unitie each other, and in which all the individuals are fused into an outward unity, or into a set of polypes. "They exist organically connected with each other, and are normally free only in their first generation, and, indeed, only in their earliest stage of development, and only for a short time; since the free-swimming collisted each way the stages about in the water at most for and only for a short time; since the free-swimming ciliated embryo swims about in the water at most for some hours, in order to find a suitable place for the foundation of a new polype stem. In the Coryne clavi-form polypes, the organic connection between the individuals and generations is rather more lay; the perfect gemmiparous or ovigerous individuals are pericer geminiparous or ovigerous individuals are usually quite free, often even at an early age; so that they do not attain their full development until after their separation from the "nursing" generations. In the Medusæ and Scalpæ, the generations which are connected together into one whole become more like each other." Among the Entozoa, similar attempts connected together into one whole become more like each other." Among the Entozos, similar attempts at becoming free and accomplishing a perfect growth are also described. The development of animals which do not belong to the water, but to the air, also presents similar phenomena, but in a still higher and more free stage. The propagation of the Aphides through a series of generations has been long known. In the spring, a generation is produced from the ora, which grows and is metamorphosed, and, without a previous fertilization, gives birth to a new generation, and this again to a third; and so on for ten or twelve weeks; so that in certain species which have been observed nine again to a third; and so on for ten or twelve weeks; so that in certain species which have been observed nine such changes have been noted. At last, there occurs a generation consisting of males and females, the former of which, after their metamorphosis, are usually winged; fertilization and the deposition of eggs take place, and the long series of generations recommences in the next year and in the same order.—Ref. Transactions of the Ray Society,—J. J. Steenstrup on the Alternation of Generations.

Generations.

Generations. Generations on account of its containing a narrative of the generation or pro-

name given to the first book of the Bible, on account of its containing a narrative of the generation or production of all things. The Hebrew name is Bereshith, 'in the beginning,' from its commencing with that word, Its history goes back to the very earliest ages of the human race, and extends over a period of at least 2,870 years. It gives an account of the creation, the fall of man, the settlements, genealogies, arts, religion, corruption, and destruction of the antedluvian world: of the re-peopling and division of the earth, the religion, corruption, and destruction of the antediluvian world; of the re-peopling and division of the earth, the dispersion of its inhabitants, the calling of Abraham, the rise and progress of the Jewish nation, &c. It is divided into two main parts, one universal and one special; the former being the ancient history of the whole human race, contained in chapters I.—XI., the latter the early history of the children of Jersal (XII.—L.). There are some critics who maintain that this book was not written by Moses; and there are certainly some passages of it that must have been written by some one after his death, as they refer to subsequent events; but that the book as a whole was Genii

written by Moses, there is little room to doubt. Much ingenious speculation has been expended, as to the manner in which Moses was made aware of what had taken place so many centuries before his own time. According to some, the different events recorded in the According to some, the different events recorded in the book were divinely revealed to him; others hold that he acquired his knowledge of them by tradition; and a third class, that he obtained it from old documents. The second of these is the commonly received opinion in this country, and the third is that which is generally maintained by the German theologians of the present day. Neither of the arriver second a "little present". day. Neither of these views necessarily militates against the belief in the inspiration of the book; for that divine gift would be necessary to enable him to distinguish the true from the false. We cannot help thinking, however, that if either or both of these had been the sole or only sources whence Moses had drawn his information, there would have been some allusion to, or evidence of it, in the book itself. His knowledge of the later events may, and probably was, obtained in this way; but we incline to the opinion that the earlier part of the book must have been the subject of divine revelation. book must have been the subject of divine revelation. For those that believe in prophecy, there is 'nothing hard of belief here; the one being a divine revelation of the future, the other a divine revelation of the past (Regarding the various subjects of controversy in this book, see CERATION, DELUGE, &c.) The authenticity of Genesis was distinctly recognized by Christ, and passages from it are cited in the New Testament, twenty-seven times literally, and thirty-eight times substantially.—Ref. Graves On the Pentateuch; Horne's Introduction to the Kernburger. Eighborn's Kinleting Introduction to the Scriptures; Eichhorn's Einleitung in's Alte Testament; Jahn On the Books of the Old Testament; Turner's Companion to Genesis.

Testament; Turner's Companion to Genesis.

Genii, je'-ne-i (Lat.), among the Romans were supernatural beings, corresponding to the demons among the Greeks. According to them, every human being had his genius allotted to him at birth, who guided and accompanied him through life, and conducted him out of the world at the close of his career. But not only persons but places, and even inanimate objects, were fabled to have their genii. The collective Roman people also had their genius, who was sometimes represented on coins. Those of the collective from a people also had their genius, who was sometimes represented on coins. Those of the women were called Junones. They sometimes held that each person was accompanied through life by two genii, a white and a black; the former good and favourable, the latter bad and unfavourable; at other times they believed in but one, which was black and white by turns. Divine honours were paid to the genii; and it was usual for each one to offer sacrifices to his genius on his birthday. The genii or diinns of the Rast hear was usual for each one to oner sacrinees to his genius on his birthday. The genii or djinns of the East bear little resemblance to those of the Romans. They are regarded as an intermediate class of beings, between angels and men, but inferior in dignity to both; and are not objects of worship. In poetry they are described as having been created out of fire, and as having scribed as having been created out of fire, and as having inhabited this world before its occupation by man, as the subjects of a certain Ján Ibn Ján. They rebelled, and God sent his angel Iblis, or Eblis, who, after conquering Ján Ibn Ján, rebelled against God, and set himself up in his room; whereupon God condemned him to attach providence. himself up in his room; whereupon God condemned him to eternal punishment. The djinns, like men, are some good and some evil. They cat and drink, are subject to passions and death, but may live for centuries. They are capable of becoming invisible, or assuming the forms of men, beasts, or monsters, at pleasure. They frequent baths, wells, ruined houses, seas, rivers, cross-roads, and market-places. The evil genii delight in mischief for its own sake, raise and direct whirlwinds, and dry up the springs of the desert. The ghouls are a subordinate class of evil genii, haunting deserts and burial-grounds. and killing and devouring deserts and burial-grounds. The ghouls are a subordinate class of evil genii, haunting deserts and burial-grounds, and killing and devouring men and women that fall in their way. The peris, or fairies, are beautiful female genii, who believe in God, and in Mahommed, his prophet, and do good to man. The Mussulman doctors believe in the existence of diluns, as supernatural beings; but their ideas of them differ much from those of the poets and romanoers.

GERIFA, jew-i-pā, in Bot., a gen of the nat. ord. Cinchonaces. Some species have edible fruit; thus the G. americana, the lana-tree of South America, produces a delicious fruit called the genipap. In British Guiana a bluish-black dye is prepared from the injue of this fruit. the juice of this fruit.

Genius

GENISTA, jen-ie'-tă (Lat. genu, knee, in allusion to the angular or jointed appearance di its twigu), in Bot., a gen. of leguminous plants, three species of which are found wild in Britain. G. tinctoria, the dyer's broom, yields a good yellow dye, or, when mixed with woad (Isait tinctoria), a green.

GENISTYE, jen'-i-tiv (Lat. genitivus, Gr. genike), in Gram, is the name of the second case in the decicasion of nouns, generally indicating the relation expressed in English by the preposition of. "The Latin genitive," says Max Müller, "is a mere blunder; for the Greek word genike never meant genitivus. Genitivus, if it is meant to express the case of origin or birth, would in says Max Müller, "is a mere blunder; for the Greek word genike never meant genitivus. Genitivus, if it is meant to express the case of origin or birth, would in Greek have been called gennetike, not genike. Nor does the genitive express the relation of son to father. For though we may say 'the son of the father,' we may likewise say 'the father of the son.' Genike in Greek had a much wider, a much more philosophical meaning. It meant casus generalis, the general case, or rather the case which expresses the genus or kind. This is the real power of the genitive. If I say a bird of the water,' of the water' defines the genus to which a certain bird belongs; it refers it to the genus of water-birds."—(Lectures on the Science of Language.) In English, the genitive or possessive case is marked by the addition of the letter s, preceded by an apostrophe; as, the king's son, my father's horse. When the plural ends in s, the additional s of the genitive is omitted, and only the apostrophe'added; as, kings'sons. GENIUS, je'n-e.us (Lat., from gigno, I beget or produce), was the term applied by the aucient Romans to a class of spiritual beings which attended upon man. Every human being, according to them, had his special genius allotted to him at birth, to guide and direct him through life; and his general character and conduct was ascribed to the influence of his genius hence the word came to signify the natural powers and sbilities of men, more especially their natural inclina-

hence the word came to signify the natural powers and abilities of men, more especially their natural inclina-tion or disposition. In modern times it has come to be employed in a still more restricted and special sense, as signifying the very highest condition of the mental powers, the perfection of human intelligence. Like many other words of a similar kind, it is difficult or impossible to define it in words; but there is always or impossible to define it in words; but there is slways associated with it the idea of creative or inventive power. According to Emerson, it is the "constructive intellect" which "produces thoughts, sentences, poems, plans, designe, systems. It is the generation of the mind, the marriage of thought with nature." "The thought of genius is spontaneous; but the power of picture or expression in the most enriched and flowing nature implies a mixture of will, a certain control over the apportaneous states without which no productive. over the spontaneous states without which no produc-tion is possible." Genius produces what has never tion is possible." Genius produces what has never before been accomplished; "it is the advent of truth into the world, a form of thought now for the first time bursting into the universe, a child of the old eternal soul, a piece of immeasurable greatness." Its chief faculties are the reason and the imagination; and according as one or other of these faculties predominates, it becomes either scientific or artistic. "In the first case it seizes at once those hidden affinities which otherwise do not reveal themselves except to the most patient and rigorous application, and, as it were, intuitively recognizing in phenomena the unalterable and eternal, it produces truth." In the latter it seeks "to exhibit its own ideal in due and appropriate forms; it realizes the infinite under finite types, and so creates the beautiful." Genius is sometimes used to signify that talent or aptitude which we receive from nature for excelling in any one thing whatever. Thus we speak of a genius for mathematics as well as a genius for poetry; of a genius for war, for politics, or for any mechanical employment. The distinction between mechanical employment. The distinction between genius proper and talent is thus given by De Quincey:—
"Genius is that mode of intellectual power which moves in alliance with genial nature, i.e., with the capacities of pleasure and pain; whereas talent has no vestige of such an alliance, and is perfectly independent of all human sensibilities; consequently, genius is a voice or breathing which represents the total Lature of man, and therefore his enjoying and suffering nature; whilst, on the contrary, talent represents only a single function of that nature." And hence, also, it is, that, "besides its relation to suffering and cujoyment, genius always implies a deeper relation to virtue and vice; whereas talent has no shadow of a relation to moral qualities, any more than it has to vital senso."

CEES, jess (Lat.), was a term applied, in ancient Rome, to a clan or party, which included several families under a bond of alliance, whose religious ceremonies, sacrifices, &c., were performed in common. Persons who belonged to the same gens were called gentiles, and those of the same family were distinguished. gentiles, and those of the same family were distinguished by the term agnati. At first patricians only oould have the honour of being gentes; but, after the law passed which enabled the plebeians to intermarry with the higher ranks, the latter class likewise were admitted to share in the clanship; and hence there were both patrician and plebeian gentes, which, of course, often assimilated, by reason of the intermarriage law. The gens Cornelia may be mentioned as an instance of a gens: it embraced the families of the Lentuli, the Scipiones, the Cethegi, and many others too numerous to mention.

GENTIAN. (See GENTIANA.)
GENTIANA, jen-she-ai'nd, in Bot., the typical gen.
of the nat. ord. Gentianaces. The officinal gentian,
so well known for its bitter tonic properties, is the
root of G. lutea, a native of the mountains of central
and southern Europe. From gentian the Swiss prepare a spirit much prized by them as a stomachic.
The genus is stated to have been named after Gentius,
a king of Sclavonia, who discovered if

a king of Sclavonia, who discovered it.

GENTIANACEE, jen-she-an-ai'-se-e, in Bot., the Gen tiana fam., a nat. ord. of Dicotyledones, sub-class Corolliforæ. Herbs, or rarely shrubs, usually smooth. Leaves flora. Herbs, or rarely shrubs, usually smooth. Leaves usually simple, entire, opposite, sessile, and strongly ribbed; rarely alternate, or stalked, or compound; always exstipulate. Flowers almost always regular, variously coloured, axillary, or terminal. Calyx inferior, persistent, usually with five divisions, occasionally four, six, eight, or ten. Corolla persistent, its divisions corresponding in number to those of the calyx; estivation imbricate, twisted or in duplicate. Stamens as many as the segments of the corolla, and alternate with them. Over Lealled or provide the called with them. Overy 1-celled, or rerely pertially 2-celled, from the projection inwards of the placentas, with numerous ovules; placentas 2, parietal, anterior and posterior to the axis, and frequently turned inwards; style 1; stigmas 2, right and left of the axis. Fruit capsular, 2-valved, with septicidal dehiscence, or a berry. Seeds numerous and small; embryo minute, in the axis of fleshy albumen. The order has been divided into two sections or sub-orders, the characters of which are taken from the æstivation of the corolls. of which are taken from the estivation of the corolls. These are, Gentianeæ, with the corolls imbricate-twisted, and Menyantheæ, with the corolls plaited, or in duplicate. The plants included in the order are found in nearly all parts of the world, even in the coldest and the hottest regions. A bitter principle almost universally pervades them; hence many are used medicinally for their tonic, stomachic, and febrifugal properties. There are 64 genera and about 450 exercise.

GENTILE, jen'-tile (Lat. gentilis, from gens, a nation), a term used in Scripture to denote a pagan, or worshipper of idols. The Jews classed all the inhabitants shipper of idols. The Jows classed all the inhabitants of the earth, with the exception of their own peculiar race, under the general name of goim, which is equivalent to the Latin gentes, nations; and after a time the term Gentiles began to be applied in a reproaching instead of a general sense. All who were not circumcised and Jews, were regarded as Gentiles or heathens, and as such they were excluded as much as possible from all those privileges and relations by which the Jewish nation became so exalted. As the Gentiles were consequently, considered as outcasts and aliens were consequently, considered as outcasts and aliens were, consequently, considered as outcasts and aliens from the favour of God, it is not much to be wondered at that the Jews were very prejudiced against a Saviour and a Gospel which inculcated the union of the

man to the appellation of gentleman, or to determine a standard by which persons who claim to hold this rank, as undoubtedly it is, may be distinguished from those who possess no right to it. It is generally applied to all who compose the bulk of the great middle class of English society, consisting of professional men, merchants, and others largely engaged in trade and commerce, and all whose income or education raises them above the lower classes of the trading community. Strictly speaking, it is the title of one who bears coat-armour, and takes rank next to an equire and above a yeoman, or, according to the definition given by Jacobs, in the Law Dictionary, "one who, without any title, bears a coat of arms, or whose ancestors have been freemen; and by the coat that a gentleman giveth he is known to be, or not, descended from those of his name that lived many hundred years since." It of his name that lived many hundred years since. may therefore be said, with ruth and justice, that one who inherits the right to bear coat-armour from his father, and his mother if she be an heiress, is bond fide father, and his mother if she be an heiress, is bond fide a gentleman by indisputable right, and, if it were worth while to contest the point, is entitled to take precedence of all others to whom the title is conceded in virtue of their professional standing, income, or education. The original derivation of the word is from the Lat. gentilis, belonging to a tribe or gens, and home, a man. In the early days of Rome, the inhabitants of that city were divided into two classes,—the populus, or that portion of the community in whom all power lay, and the plebs, or commonalty. The populus, or body of the patricians or nobles, was further divided into tribes or gentes, and each gens into families, all the members of which bore the common appellation of the tribe. To belong to a gens or tribe, was to take the members of which bore the common appellation of the tribe. To belong to a gens or tribe, was to take rank among the nobles, and in after-times, when the privilege of admission to a tribe was conceded to men of plebeian origin, it was equivalent to the grant of a title of nobility by letters patent from the crown in our own times. Hence the term gentilis was applied to all who were free-born, being descended from free-born ancestors and belonging to a noble family; while that of sine gente, without family or standing, was applied to men of low rank and origin, and those that were

ancestors and belonging to a noble family; while that of sine gente, without family or standing, was applied to men of low rank and origin, and those that were born of slaves. The term has been adopted in all European languages of which Latin forms the foundation-stone and parent stock; while it is found in our own language in the word "gentleman," and gives the clue to the meaning of the expression "gentle," well-born, in contradistinction to its opposite "simple."—Ref. English Cyclopadia,—Arts and Sciences.

GENTLEMEN-AT-ARMS, a band of fifty gentlemen who were enrolled by Henry VIII., in the year 1509, to attend strictly about the royal person. They were first denominated "spears," but were afterwards called "gentlemen pensioners," which name they bore until the year 1834, when they were called gentlemen-at-arms. The members are elected exclusively from officers in the army or navy, who enjoy their half-pay at the same time that they receive their pension as gentlemen-at-arms. The officers are a captain, who has £1,000 per annum; a licutenant, with a salary of £500; a standard-bearer, with £310; a clerk of the cheque with £120; and forty gentlemen with £70 per annum each. The duty of the gentlemen-at-arms, in the present day, is principally to attend at drawing-rooms and leyees. What when they were first originateper annum each. The duty of the gentlemen-at-arms, in the present day, is principally to attend at drawing-rooms and levees; but when they were first originated, they had the exclusive privilege of bringing in the royal dinner, and placing the same on the table, a service which they still have the honour of performing at coronations; in reward for which latter service, the sovereign has often conferred the rank of knight-back on each of the follows or gentlemen of the bund. hood on one of the officers or gentlemen of the band, ordering the fees for the same honour to be paid out of the treasury. Their uniform is decidedly military, and very similar to that of the foot-guards, although on some occasions it has been assimilated with the

caviour and a cospel which inculcated the union of the two different sects, and placed the Gentiles on an equal footing with the Jews. Those of the Gentiles of the Gentiles of the Gentiles of the Gentiles of the many section in the New Testament, is sometimes identical with Gentiles.

Gentiles, Gentiles, Gentilhomme, from gentilloff, of good birth, and home, man).—It is a matter of difficulty to give a correct definition of what entitles a genera has thus become more copious as the study of the good birth.

natural history has progressed, and presents one of the difficulties which the student of zoology has to contend against. (See Special).

Genus, in Bot, the term genus is applied to a collection of species of plants which resemble one another in general structure and appearance, more than they resemble any other species. Thus the various kinds of brambles constitute one genus; the roses, another; the heath, willows clovers cake and as forth force. of brambles constitute one genus; the roses, another; the heaths, willows, clovers, oaks, and so forth, form also, in like manner, so many different genera. The characters of a genus are taken exclusively from the organs of reproduction, while those of a species are derived generally from all parts of the plant. Hence a genus may be defined as an assemblage of species which resemble one another in the structure and gene ral characters of their organs of reproduction. It does not necessarily happen that a genus should contain a number of species; for if a single one presents peculiarities of a marked kind, it may of itself constitute a genus.

GROCENTRIC, je-o-sen'-trik (Gr. ge, the earth, and

tention, a point, centre), an expression that is applied to the position of a planet as it would appear to an observer stationed at the centre of the earth. It is opposition to the term heliocentric, which is used to denote a planet's position as it would be seen by an observer at the centre of the sun.

Observer at the centre of the sun.

GROUN, jet-ods (Gr. gaiodes, earthy, from ge, the earth), in Min., a term applied to a round lump of agate, or other mineral, or to a mere incrustation of the same. Its interior is sometimes empty, and in that case the sides of its cavity are lined with crystals, as in agate balls. Sometimes it contains a solid movable nucleus, and sometimes it is discovered to be supported by the contains a solid movable nucleus, and sometimes it is discovered to be tilled with an earthy matter different from the external envelope.

GEODEY, je-od'-e-se (Gr. ge, the earth; daio, I di-vide), that science which enables us by measurement and direct observation to determine approximately the shape or figure of the earth, and ascertain the area of its entire surface, or any part of it, as well as the varia-tions in the force of gravitation at different parts of the earth. The figure of the earth was known to be nearly spherical some time prior to the Christian era, and even in the present day we are taught to consider its form to be that of a regular oblate spheroid, or its form to be that of a regular oblate spheroid, or sphere flattened at the poles, which is a sufficiently close approximation to its actual shape for all general and practical purposes. If the latitudes and longitudes of places on the earth's surface, deduced from geodetic measurements, coincided with those obtained from astronomical observations, the form of the earth would be that the form of the earth would be that of a regular spheroid of rotation; but there is such a difference in the results obtained by the two methods, that no regular shape can be assigned to the earth by which these results can be reconciled. measurements of arcs of the meridian that have been made during the 18th and 19th centuries, in various parts of the world, have, however, tended to show that the diameter of the earth from pole to pole is, to its diameter at the equator, as 289 to 300; but they have also served to prove that there is a dissimilarity of shape between the northern and southern hemispheres, and that the curvature of the earth's surface is different in meridional arcs of either hemisphere, that are at no great distance from each other; which shows that the earth cannot be a regular spheroid. The discrepancy in the shape of the hemispheres, and the irregularity of curvature in different parts of the same hemisphere, can only be accounted for by the supposition that the earth was once in a fluid state, and that the irregularity in the cooling, and consequent solidification of various parts, had produced a corresponding irregularity of form in its surface, and a departure from the uniform spherical shape, which it would have undoubtedly assumed under the influence of centriugal force, if the whole mass had been homogeneous, and the conditions under which it had cooled had been the same at all parts of its surface. The following is a brief notice of some of the more important attempts that have been made to obtain accurate measurements of arcs of the meridian at different parts of the earth's surface, with some account of the method by which trigonometrical surveys are made for this purpose, and for determining the area and obtaining correct delineations of large 922

tracts of country. Eratosthenes was the first who at-tempted to determine the length of a geographical degree, about 250 s.c. A degree was also measured in the plains of Mespotamia, rather more than a thousand years after, by order of the caliph Al Ma-moum; and in 1617 Willebrod Snell measured a degree of the meridian at Landon and assistant distributed. moum; and in 1017 whienrod duen measures a segree of the merdian at Leyden, and estimated it at about 68-75 English miles. There were, however, some errors in Snell's calculations, which he had detected himself, in Snell's calculations, which he had detected himself, but which he was prevented from correcting by his death in 1628. In 1633, Norwood measured the meridian from London to York, and obtained a tolerably accurate value of the degree. In 1671, Picard and La Hire effected the measurement of the meridian between Amiens and Paris, and obtained a result of 691 English miles as the length of a degree. This was followed, in the commencement of the 18th century, by the extension of the measurement of the meridian by the extension of the measurement of the meridian by the extension of the measurement of the meridian begun by Picard, to Dunkirk towards the north, and Collioure, in the Pyrenees, towards the south, when James Cassini, under whose direction the operation was completed, found the length of a degree between Paris and Dunkirk to be rather less than the result which was obtained by Picard, and also less than the length of a degree between Paris and Collioure, which gave rise to an idea that the length of a degree of the gave ruse to an aces that the tengua or a negree or one meridian must grow less in proportion to its distance from the equator, instead of greater, as it must do of mecessity if the form of the earth be that of an oblate spheroid. This caused Cassini and others to conjecture that the earth must be in the form of a prolate spheroid; that the earth must be in the form of a prolate spheroid; but this idea was shown to be erroneous by the measurement of an arc in 1736, in Lapland, to the north of the Gulf of Bothnia, from which it appeared that there was an increase, instead of a decrease, in the length of a degree of the meridian in proportion to its distance from the equator, although it was discovered that their computation errod in excess when a measurement. from the equator, attaongh it was discovered that their computation erred in excess when a re-measurement of the arc was made by Svanberg in 1802. While Maupertuis was measuring an arc of the meridian in Lapland, Bouguer and La Condamine, assisted by some Spanish officers, were performing the same operation near Quito, in Peru, an iron toise being used as the standard of measurement, which has since been adopted as the standard for the expression of the length of the greater number of the degrees that have been measured on the continent, all of them, indeed, laving been ultimately referred to this as the unit of measurement. In the measurement of the arc effected in Pern, the length of a degree was found to be about 68.72 English miles by the French mathematicians, and rather more by the Spaniards. The results, however, of the two measurements effected simultaneously in Peru and Lapland went far to prove that the form of the earth was that of an oblate spheroid. In 1752, Lacuille measured an arc of the meridian at the Cape of Good Hope, from which operation he obtained a result nearly equal from which operation he obtained a result nearly equal to the length of the degree measured by Picard be-tween Paris and Amiens, although the scene of his labours was about 30° south of the equator, while that part of France selected by Picard is 50° to the north of it; and, according to the received theory of the oblate-spheroidal form of the earth, the length of the degree measured at the Cape ought to have been less than that which was assigned to it by Leccille. The disthat which was assigned to it by Lacaille. The dis-crepancy has, however, been accounted for and ex-plained by Maclear, who has lately remeasured La-caille's arc. In 1791 the arc of the meridian of Paris was remeasured from Dunkirk to Barcelons, by order of the French Convention, to establish the length of the mètre, the new French standard of measurement, which was to be the ten-millionth part of a quadrant of the meridian. This was carried out with great care by which was to be the ten-minimonal part of a quantum on the meridian. This was carried out with great care by Delambre and Mechain; but an error has since been discovered in the work, which affects the length of the measured are to the extent of nearly sixty-eight toises, and makes the mètre to be shorter than it should be by a very small and trifling fraction of its present length.
The trigonometrical survey of the British isles was brought about by the means taken to establish a con-nection between the observatories of Paris and Greendection netween the conservatories of raris and threm-wich, which was effected by carrying a series of triangles from Greenwish to Dunkirk; this was performed by General Roy with great accuracy. The survey itself was commenced in 1791 by Gelonel Williams and

General Mudge, and has been continued by General Colby, Cotonel Hall, and Colonel James, who have been successively superintendents of the Ordnance Survey. In connection with the survey, an arc of the meridian was measured from Dunnose, in the Isle of Wight, to Saraford, in the Shetland islands; embracing an extent of nearly 10° 18°, the length of the arc being found to be a little more than 700½ English miles. In the course of this survey, bases of verification were measured on Housslow Heath, Salisbury Plain, and Misterton Carr in England; on Ehuddlan Marsh, in Wales; on Belhelvic Links, near Aberdeen, in Scotland; and on the shores of Loch Foyle, in Ireland. The base on Sslisbury Plain was remeasured in 1849. The trigonometrical survey of India was commenced in 1801, by Colonel Lambton, who measured an arc of the meridian from Punnee, near Cape Comorin, to Damargida, near Beder, in the Nizam's territories. He was succeeded by Colonel Everest, who continued the system of triangulation from Damargida to Kalianpur, in the plain of Seronj. Colonel Everest, however, considered that the work performed by Colonel Lambton and himself had not been carried out, from various causes, with that degree of nicety and precision which should distinguish works of this nature. He therefore recommenced his labours in 1830, from which the most satisfactory results were obtained, an arc of the meridian having been mest accurately measured by him, assisted by Captain Waugh and Captain Rennie, from Kaliana, near the Himalayas, to Damargida, the differ-ence of the results of the actual measurement of the basis of verification, and their length when computed basis of verification, and their length when computed from each other being but a few inches. The extent of the arc measured from Kaliana to Damargida, by Colonel Everest, was 11°27′33″; while that from Damargida to Punnee, measured by Colonel Lambton, was 9°53′40″; giving an entire length of 21°21′13″. In Europe, during the present century, General Krayenhoff has made a trigonometrical survey of Helland which is a continuation of Delamber's averser. Holland, which is a continuation of Delambre's survey of France. A survey of the Russian empire has also been made, and an arc of the meridian has been measured under the auspices of the Swedish and Russian sured under the auspices of the Swedish and Russian governments, extending from Fugelnaes, on the Arctio Ocean, to Ismail, on the Danube. This includes that portion which was measured in Lapland by Maupertuis, and subsequently by Svanberg. It is the largest are that has yet been measured on the surface of the earth, its length extending over 28° 8′. Two small arcs of the meridian have also been measured in Denmark and Hanover, with great care and accuracy; and an arc of the meridian of Königsberg, in Prussia, by Bessel, when he was engaged in connecting the triangulation of the Russian survey with that of Central Europe and France and England. By means of these surveys, all the principal observatories of the continent of Europe have been connected by a system of triangles, and the geodetical position of its chief cities, and most striking physical features, have been ascertained by actual measurement. In commencing a trigonometrical survey, the first thing to be done is to obtain a base-line, in terms of which the sides of the triangles and distances from station to station are to be computed. To effect this, a piece of ground is selected that is as level and open as possible. The extremities of the base are then marked by the intersection of lines on a plate of metal that is fixed on a block of wood driven firmly into the ground. The course of the line is determined by setting pickets in the ground between the extremities, in the manner adopted for setting out a straight line in surveying. (See Surveying.) The distance from one and of the base to the other is then measured with the most scrupilous care by means of chains or rods, with various appliances to correct their expansion or contraction under the influence of changes in the temperature of the atmosphere. The best of all the different kinds of measuring-rods that have been proposed for effecting this portion of the work with accuracy, seem to be the apparatus of compound bars of zinc and mon which Bessel used to measure the base for the Prussian survey; and that anyented by Colonel Colby, consisting of bars of brass and icon, with steel tongues at right angles to the bars at either end, by which the base on the shore of toch Foyle was measured. As 029

soon as the base has been measured from end to end its length is ascertained on a great circle of the earth, in terms of the standard to which the measuring rods have been referred. But in order that the results of different surveys may be more easily compared, the radius of this circle must be determinate, or, in other words, the radius of the earth at the level of the sea, and the length of the base obtained at a height above the sea-level, must be reduced to its length at the mean level of the sea, which is found by dividing the measured length of the base multiplied by the radius of the earth, by the sum of the earth's radius and the height above the sea-level at which the measurement of the base has been made. When this has been done, the triangulation is commenced, stations being chosen which form the angular points of the princi-pal triaugles. In doing this the sides of the triangles should be made as long as may be practicable, and angles that are very acute should be avoided; for if the length of the sides of the triangles be as great as may be possible, and their angles not too acute, but approaching as nearly as may be to an angle of 60°, there will be less lisbility to error, since a very slight disorepancy in the measurement of an extremely acute angle will give rise to considerable error in the length of any side of a triangle that may be computed from it; and in triangulation from any base, the greater the number of intermediate triangles the greater will be the error of a distance computed through the whole system of a distance computed through the whole system of triangles. After determining the stations, signals are erected, from which the angles of the triangles are measured by means of the theodolite. When the measured by means of the theodolite. When the stations are at a great distance from each other, lamps with reflectors have been used as signels when the observations have been made by night; and plates or hemispheres of polished metal, or pieces of lockingglass, as in the heliotrope invented by Gauss, when they have been taken by day. In observations made by day, piles of stones or wood have also been erected as signals which have been visible with a powerful telescope even at the distance of a hundred miles. When the observations have been made, the angles are When the observations have been made, the angles are reduced to the centre of the station, if the theodolite has been removed from the vertical line, passing through the signal itself, and forming its axis, to a position on either side of it, or in front of or behind it; and they are also reduced to the horizon by trigo-nometrical formulæ. They are also further corrected with regard to spherical excess, and their relation to each other through the whole system of triangles, and the length of the sides of the various triangles is then computed by the aid of trigonometry. As it requires an extensive knowledge of the science of mathematics to enable any one to comprehend the minutise of the operations, and the calculations by which geodetic surveys are effected, and the results obtained, it will be manifestly out of place here to give more than the above brief notice of the more practical features, in above brief notice of the more practical features, in such an elaborate and difficult operation, that may be intelligible to the general reader, and to refer those who may desire a greater insight into the science, to works written by those who have been engaged in carrying out the chief trigonometrical surveys in England and Wales, and on the continent. It should, however, be mentioned, that, in obtaining data for deli-neating the physical features of a tract of country contained within the limits of each of the great triangles of the entire survey, the surface thus bounded is subdivided into smaller or secondary triangles, and is subdivided into smaller or secondary triangles, and the position of the intermediate objects effected by the methods adopted in ordinary surveying.—Ref. Delambre's Méthodes Analytiques pour la Détermination d'un Arc du Méridien; Puissant's Traité de Géodésie; English Cyclopædia,—Arts and Sciences; Encyclopædia Metropolitana,—Figure of the Earth; Everet's Account of the Meavement of Two Sections of the Meridional Arc of India; Clarke's Account of the Principal Triangulation, dc., relating to the Ordnance Survey of the British Isles.

GROGMOSI. (See GEOLOGY.)
GROGMAPHIOLI DISTRIBUTION OF ANIMALS. (See

GROGRAPHICAL DISTRIBUTION OF ANIMALS. (See DISTRIBUTION OF ANIMALS.) GROGRAPHICAL DISTRIBUTION OF PLANTS. (See PLANTS, DISTRIBUTION OF.)
GROGEAPHY, je-og'-raf-e (Gr., from ge, the earth,

and graphe, a description), is that science by means of which we obtain a knowledge of this earth, both as it is in itself and at it is connected with a system of other similar bodies. It comprises a knowledge of its figure and dimensions; of the natural features, divisions, and productions of its surface; of the position of the various places upon it; and of its various inhabitants. It is usually arranged under three principal branches,—Mathematical, Physical, and Political. Mathematical Geography deals with the earth principally in its planetary relations, as a member of the solar system; a great part of this being common to it with astronomy; and hence it is sometimes termed astronomical geography. It treats of the figure, magastronomical geography. It treats of the figure, mag-nitude, density, and motion of the earth; of the movements of the other heavenly bodies which exert an influence upon it; the relative positions and distances of the various places upon its surface; and the representation of the whole or portions of its surface upon globes or maps. By mathematical geography, we ascertain that the earth is spherical in form, or rather what is called an oblate spheroid, being a little flatter what is called an oblate spheroid, being a little flatter. what is called an oblate spheroid, being a little flatter at the poles than at any other part of its circumscrence; that its mean diameter is 7,913 English miles, the equatorial exceeding the polar by 26 hiles; that its orbit round the sun is slightly elliptical, while its mean distance from that luminary is about 95,000,000 of miles; that it performs its revolution in 365 days, 5 hours, 48 minutes, 50 seconds, the mean rate at which it travels being about 68,000 miles an hour; that the eath has also a motion round its own axis, which it completes every twenty-four hours, and that it revolves round the sun with its axis constantly inclined to the round the sun with its axis constantly inclined to the plane of its orbit at an angle of 66° 32″. To the former of these motions we are indebted for day and night; to the latter, for the vicissitudes of the seasons. In order to determine the relative positions of different places upon the earth's surface, geographers have supposed certain lines or circles traced upon it. One of these, the equator, being equally distant from both poles or points of rotation, divides the earth into two hemispheres, the northern and southern. Another encircling line drawn at right angles to the equator and passing through the poles, divides it into the eastern and western hemispheres. Parallel to the equator and numbered from it, are the lines or degrees of latitude, of which there are ninety in the northern, and as many in the southern hemisphere. The equator is divided into 360 equal hemisphero. The equator is divided into 360 equal parts, and lines drawn perpendicularly from the points of division to the poles constitute the lines or degrees of longitude. They are numbered east and west from a certain meridian, as that of Greenwich, Paris, Washington, &c. The meridian of a place is a line passing through that place to the poles at right angles to the equator. All places lying in the same latitude have equal length of day and night at the same time, while all places in the same longitude have mid-day at the same length at the equator; but the former, on account of the flattening of the surface of the globe, are slightly elongated towards the poles, while the latter are slightly elongated towards the poles, while the latter gradually diminish in length as they recede from the equator. The length of a degree of longitude at the equator is 69 06 English miles. Each degree is divided into 60 equal parts termed minutes, and every minute into 60 equal parts termed minutes, and every minute into 60 equal parts termed/seconds; marked thus, ° '". On maps, the latitude is denoted by figures at the sides, the longitude by figures at the top and bottom. The top of a map is the north, the bottom the south, the right hand the east, and the left hand the west. As the earth revolves round the sun with its axis constantly inclined to the plane of its orbit at a considerable angle, it follows that the sun does not remain perpendicular to the equator; but is one half of the perpendicular to the equator; but is one half of the year to the north and the other to the south of it. An imaginary circle, marking the sun's vertical position with regard to the earth, is termed the celiptic, and cuts the equator obliquely at two points, termed the equinoctial points or nodes, the sun being then vertical to the sun that the sun terms of the sun terms of the sun terms. equinocusi points or nodes, the sun being then vertical to the equator. The vernal equinox occurs on the 21st of March, the autumnal on the 21st of September. The sun is vertical at different times of the year to all that portion of the earth's surface tying between 23°28' N. and 23°28' S. of the equator; and this region being subject to the greatest amount of heat, is called 924

the Torrid Zone, and is bounded on the north by a circle termed the Tropic of Cancer, and on the south by another termed the Tropic of Capridorn. The sun is on the parallel of 23° 28' N. on the 21st of June and on the parallel of 23° 28' S. on the 21st of December; termed respectively the summer and winter solstice. From this inclination of the earth's axis, it also follows that the whole region within 23° 28' of either pole, or, in other words, above 66° 22′ of N. or S. latitude, is, for a certain period of the year, involved in continual night or continual day. The northern of these regions is termed the North Frigid Zone, and is bounded by the Artitic girlls: the southern the South Friend Zone. is termed the North Frigid Zone, and is bounded by the Arctic circle; the southern, the Bouth Frigid Zone, and bounded by the Antarctic circle. Between the tropic of Cancer and the Arctic circle is the North Temperate Zone; and between the tropic of Capricorn and the Antarctic circle is the South Temperate Zone,—Physical Geography comprehends a description of the principal features of the earth's surface, as consisting of land and water, the different animal and vegetable products; climate, elevation and direction of mountain-chains, &c. (See PRISICAL GEOGRAPHE.) Political Geography describes the countries and nations of the earth as they are politically divided, and deals with mankind in their social aspect and organization. It gives an account of the laws and government of the different countries, their language, religion, civilization, resources, all of which fell to be treated of in the presources, an or which fell to be treated of in the pre-vious volume of this work, under the names of the different countries. Geography, in its practical appli-cation, "has for its object the determination of all those facts, as to any given country, which will enable us to judge of its fitness to provide man with food and to promote his civilization." It is thus a subject of the utmost importance; for it is well known that outward circumstances exert a very manifest influence upon mankind. The climate and physical characteristics of a country determine, in a good measure, the nature of its inhabitants, and its productions guide their pursuits, In order to convey a minute and correct account of a country, it is necessary for the geographer to separate the different parts from each other, and give a partic-ular account of each, following some general plan. The following plan will be found to be pretty complete; but of course it may require to be more or less modified, to out ourse it may require to be more ress monther, to suit particular cases.—Physical features: including an account of position, extent, and natural divisions of the country; its boundaries; the extent and character of country; it's boundaries; the extent and character of its coast; the height, form, and direction of its mountains; the extent and elevation of its plains; the character of its valleys; the length, direction, size, and velocity of its rivers; the nature and extent of its lakes and marshes; its springs.—Climate: account of, including variations of temperature; fall of rain; direction of prevailing winds; atmospheric pressure.—Geology: comprising an account of its geological formation, its various mineral resources, and the character of the soil.—Botany and Zoology: the number and distribution of the various species of animals and plants, their uses a ministering to the precessities or comforts of the of the various species of animals and plants, their uses a ministering to the necessities or comforts of the people, as supplying them with materials for labour, or as furnishing them with articles of trade.—Agriculturs: the extent of cultivated land, heaths, forests, pastures, &c.: state and progress of agriculture; modes of cultivation; agricultural implements; fertility of the soil; the different kinds of crops; their amount, and the proportion they bear to the wants of the people; the number of the various kinds of cattle, and their uses in agriculture or domestic economy.—Mining: the number, character, and productiveness of the mines; the ountities and values of the different ores raised; the quantities and values of the different ores raised; the progress of mining, and the modes of carrying on operations.—Fisheries: the various kinds of sea and river fisheries; their importance, and the means and manner of prosecuting them.—Manufactures: their progress and present state; the different branches of manufacture; their principal seats; their importance as contributing to the wealth of the country, or as affording employment and means of subsistence to the people; the amount and value of the labour expended upon them; the machinery employed; how far the raw materials are home-produced or imported; how far the manufactured articles are necessaries or luxuries; and how far they are for home consumption, or for exportation,—Commerce: the amount of the exports and quantities and values of the different ores raised; the

imports; the quantities and values of the principal articles; the principal ports; the countries with which trade is chiefly carried on, and the principal articles exported to or imported from each; by whom or underwhat flags the trade is principally carried on; how far the imports are necessaries or luxuries; how far for direct consumption, for manufacture, or for exportation; how far the exports are raw or manufactured goods, are the natural production of the country, or imported or manufactured. It comprehends also an account of the nature, amount, &c., of the internal or coasting trade.—Facilities for Commerce: the amount of shipping belonging to the country, distinguishing sailing from steam vessels; the character of the harbours; length of the navigable rivers and canals; nature and length of the roads and railways; nature of the conveyances.—Fopulation; the number of the nature and length of the roads and railways; nature of the conveyances.— Population: the number of the people at different times; the different races; rate of increase; emigration and immigration; proportion of the sexes, and the marriage relations; the different ages of the population; the average duration of life, and how affected by locality, climate, occupation, or mode of life; the nature and prevalence of certain diseases; the proportion of the population to the production, wealth, and consumption of the country.—Social Condition: the general character, disposition, and habits of the people; their manners and customs; their progress in civilization; the different classes of society; their numbers and relations to one another; the social condition and intellectual and moral culture of each; the number of and relations to one another; the social condition and intellectual and moral culture of each; the number of houses; distribution of wealth and power; occupations of the people; the proportion of capital to labour; skilled and unskilled labour; wages; price of provisions; amount of chief articles of consumption; national vices; pauperism.—Language and Literature: character and growth of the language; different dialects; affinity with other languages. The character, condition, and progress of its literature; the several branches in which it is principally distinguished; names of the principal and the of the principal authors; different classes of publica-tions; literary associations; public libraries; restric-tions on literature, or liberty of the press.—Science and drt: state and progress of; branches in which the country is chiefly distinguished; institutions for the promotion of, as academies, scientific associations, museums, picture-galleries, &c.—Government: its nature, form, and progress; the legislative, judicial, and executive functions, in whom vested, and how carried out the absence of its laws, the relief in the country is the second of the legislative. out; the character of its laws; the political divisions of the country; how far and in what way the different of the country; how far and in what way the different classes of the people are represented; public works, and other means adopted by government for the encouragement of industry and commerce, or for promoting the social and intellectual progress of the people.—

Religion: its character, condition, and history; its connection with the State; toleration; the various religious sects; number of ohurches, and extent of accommodation; the various classes of the clergy; their emoluments; the amounts and sources of the church revenues, as provided by the State, by voluntary contributions, &c.—Education: the number and character of the various seminaries of education; their efficiency; how supported; fees; the number of teachefficiency; how supported; fees; the number of teachers; their incomes; number and ages of the scholars, and their proportion to population, especially between the same ages; how far the State controls or interferes with education. — Crime: state of crime; different classes of offences; the social condition of offenders, classes of offences; the social condition of offenders, age, sex, education, &c.; number of convictions: proportion of convictions to committals; the different kinds of punishment; means employed for the punishment or detection of crime; prisons, reformatories, police, &c.—Defence: the natural defences of the country; its fortresses, &c.; the amount and efficiency of its army, navy, militia, &c.—Finances: amount of national debt, its nature and growth; the various sources of revenue; the gross and net amount received from each; proportion of income to expenditure; the various branches of expenditure.—Tazation: amount various branches of expenditure.—Taxation: amount of; its character, as direct or indirect; its several branches; the articles on which imposed; how levied; expenses of collection; how far protective or retalia-tory; effects on industry or commerce; recent altera-tions, and consequences of — Loney, &c.: the weights, 925

measures, moneys, &c., of the country, and their equivalents; banks and banking system, &c.—Antiquities: the different classes of antiquities; their character and age; their state of preservation, &c. Information on these various points, so far as they may be applicable to suy particular state or country, is necessary, in order to a thorough geographical knowledge of it, i. e., physically and socially,—in order to understand its present position, to trace the various circumstances by which it has arrived at that state, and to acquire some knowledge of the action and re-action that is constantly knowledge of the action and re-action that is constantly taking place among its various elements. The sphere of the geographer is thus a very extensive one, and demands of him to be familiar with a vast variety of anhienta

GEOLOGY, je-ol'-o-je (Gr. ge, the earth; loges, discourse or reasoning), that department of natural science which embraces all that can be known of the constitution and history of our planet. In the words of Mr. J. Beete Jukes, it is not so much one science as the application of all the physical sciences to the examination and description of the structure of the earth, the investigation of the processes concerned in the production of that structure, and the history of their action. The fact that geology rests upon all the natural sciences accounts for its modern origin. It was not till some very considerable advances had been made in all the sciences which relate directly to the earth, that geology could begin to exist in any worthy form. It was not till the chemist was able to explain to us the true nature of the mineral substances of which rocks are composed; not till the geographer and meteorologist had explored the surface of the earth, and taught us the extent and the form of land and and taught us the extent and the form of land and water, and the powers of winds, currents, rains, glaciers, earthquakes, and volcanoes; not till the naturalist had classified, and named, and accurately described, the greater part of existing animals and planta, and explained to us their physiological and anatomical structure, and the laws of their distribution in space,—that the geologist could, with any chance of arriving at sure and definite results, commence his researches into the structure and composition of rocks, and the causes the structure and composition of rocks, and no causes that produce them, or utilize his discoveries of the remains of animals and plants that are inclosed in them. He could not till then discriminate with certainty between igneous and aqueous rocks, or between living and extinct animals; and was, therefore, unable to any down any one of the foundations upon which his own science was to rest. To enable our readers to form a clear conception of the scope and methods of geology, we take the liberty of quoting the philosophical and lucid explanations given by the writer already alluded to. "There is another, and a more restricted cal and lucid explanations and a more restricted sense of the word geology, than the wide and general one in which we have been using it. This sense is rather the one formerly attached to the word geognosy (Gr. ge, the earth; gnosis, knowledge), by which we may understand the knowledge of the nature and position of the different masses of earthy and mineral matter of which different districts and countries are composed, without reference to the history of their composed, without reference to the history of their production. This was the early and simple meaning production. This was the early and simple meaning of the word geology, when considered as synonymous with geognosy; namely, the examination and description of the different varieties of rocks, and the minerals they contained. Geology was looked upon in the light of a geographical mineralogy; and even yet it is regarded more or less under this aspect by many persons. No one, indeed, could have anticipated, from the mere study of masses of stone and rock, where, to a partial and local view, all seems confusion and irregularity, the wonderful order and harmony which arise from more extended observation, and the almost arise from more extended observation, and the almost romantic, and seemingly fabulous, history which be-comes at length unfolded to our perusal. To discover comes at lengtu uniolded to our perusal. To discover the records on which this history is founded, and to understand their meaning aright, frequent long-continued and wide-spread observation and research in the field, and patient and conscientious registration, of the observed facts in the closet, are absolutely necessary. This collection and co-ordination of facts it is which is the record and co-ordination of facts it is which is the proper and peculiar business of the geognost. The ditch, the cutting, the quarry, and the mine; the cliff, the gully, and the mountain side, are

# Geology

his enbjects. These he has to study, to examine, to dissect, to describe the minutize of the structures they expose, and to classify and arrange the facts they may expose, and to classify and arrange the facts they may afford, depicting their lineaments on maps and sections, and recording them in written descriptions. The business of the geognosi, then, is to make out, from indications observed at the surface, and in natural and artificial excevations, the internal structure, the solid geometry of district after district, and country after country, until the whole earth has been explored and described. If, while so doing, he notes all those facts which may enable him or others to understand and explain how that structure has been produced, he then becomes a geologist. It might at first be thought becomes a geologist. It might at first be thought that, in order to make out the solid structure of lands and countries, it would only be necessary to understand the nature of the mineral matters of which they were composed, and that, for this purpose, no knowledge of organic or living beings would be required. It is, however, one of the most remarkable results of geological science, that an acquaintance with organic, and especially with animal forms, is at least as necessary for a geologist as a knowledge of minerals, and that a correct knowledge of organic remains (portions of lessil plants and animals) is a more certain and unerring guide in unravelling the structure of complicated districts than in unrarelling the structure of complicated districts than the most wide and general sequantance with inorganic substances. The cause of this necessity, puzzling and paradoxical enough, perhaps, at first sight, may be briefly stated as follows. When we come to examine the crust of the globe, we flud that its several parts have been produced in succession; that it consists of a regular series of earthy deposits (all called by geologist and of the complete of the constraints of the con a regular series of earthy deposits (all catted by geologists rocks), formed one after another during successive periods of time, each of great but unknown duration. Now the mineral substances produced at any one period of this vast succession of ages do not appear to have had any essential difference from those formed at another. We cannot, therefore, with any certainty, discover the order of time in which the series of rocks was formed, or the order of superposition, which they consequently preserve with regard to each other, from an examination of their mineral character or The animals and plants, however, contents only. living at one period of the earth's history were different from those living now, and different from those living at other periods. There has been a continuous suc-cession of different races of living beings on the earth, following each other in a regular and ascertainable order; and when that order has been ascertained, it is obvious that we can at once assign to its proper place of production, and therefore to its proper place in the series of rocks, any portion of earthy matter we may meet with, containing any one, or even any recognizable fragment of one, of these once living beings. Just as when we find under the foundation-stone of any socient building a parcel of coins of a particular sovereign, we know that the erection of that building took place during his reign; so when we find a fragment of a known foseil in any piece of rock, we feel sure that that rock must have been formed during the period when the animal or plant of which that fossil is a part was living on the globe, and could not have been formed either before that species came into existence or after it became extinct. In cases, therefore, where the original order of the rocks has been confused by the action of disturbing forces, or where the rocks themselves are only at rare and wide interrale exposed to view, their order of deposition and consequent succession of places, may be more casily and certainly ascertained by the examination and determination of their fossil contents than by any other method." Geology may be viewed in three great aspects,—Descriptive, Theoretical, and Fractical; Descriptive Geology being that which restricts itself to a consideration of facts and appearances as presented in the profex crust. Theoretical, that which attempts to to an appearance as presented in the rocky crust; Theoretical, that which attempts to account for the phenomena, and arrange them into a connected world-history; and Practical, that which, guided in its researches by the other two, treats of the mineral products of the globe, the methods of obtaining them, and their application to industrial or economic purposes. As a main topic, geology may also be conveniently studied under the three sub-sciences,

—Physical Geography, Mineralogy, and Palaontology;

926

### Geometry

the first treating of the surface configuration of the globe as depending on geological influences, the second restricting itself more particularly to a consideration restricting itself more paracticary to a consideration of the mineral substances which enter into the composition of the crust, and the third devoting itself exclusively to a consideration of the fossil plants and animals found in the rocky strats. Each of these subsciences can be studied intimately in detail as separate departments; yet it must be seen at a glance that without an intimate acquaintance with all the three, there can be no true knowledge of geology. Those who are anxious to study this grand and useful departwho are anxious to study this grand and useful department of natural science cannot choose a better guide than Mr. David Page, who has produced an "Introductory Text-book," for beginners, an "Advanced Text-book," and a "Hand-book of Geological Terms;" three works of remarkable excellence. With the light of the "Advanced Text-book," an earnest student may obtain a thorough insight into geology, and soon fit himself for studies in the field. The "Physical Geology" of Mr. J. Beete Jukes is an admirable work for those activaly exceed in examining district. teclogy of Mr. J. Beets Junes is an admirable work for those actively engaged in examining a district. For the poetry and romance of geology, the reader is referred to the interesting works of the late Dr. Mantell, particularly to his "Wonders of Geology." Sir C. Lyell's "Principles of Geology," and the excellent treatises of Phillips, De la Beche, Ansted, and Portlock, ought to be studied by the advanced student,

occ, ought to be studied by the advanced student. GEOMERRY, je-ome-orre (Gr., geometrien, formed of gea, the earth, and metreo, I measure), may be strictly defined to be the doctrine of the extension of such things as lines, surfaces, and solids. The attributes or properties of bodies may, in order to be more readily explained, be resolved into two classes, one comprising the general characteristics of all, and the other such only as are included in particular or negative bodies. the general characteristics of all, and the other such only as are included in particular or peculiar bodies. Extension, figure, magnitude, mobility, divisibility, impenetrability, weight, and inertia, may be mentioned as some of the properties which belong to the first class; whilst some of those in the second are solidity, liquidity, transparency, and such-like. Of all these properties mentioned, only extension, magnitude, figure, and divisibility, come under the special branch of science denominated Geometry; the different properties which remain, coming under the head of Natural Philosophy, or Physics. The important science of geometry was or Physics. The important science of geometry or Physics. The important science of geometry was first cultivated in Egypt, according to the testimony of Herodotus, which historism dates its origin from the following circumstance:—Sesostris, the king of Egypt, shared the lands at Thebes and Memphis between his subjects, and each portion was marked out by different landmarks; but, owing to the inundations of the Nile, these boundaries were frequently destroyed, and it became necessary, as often as this was done, to restore them by measurement; hence a swetem was and it became necessary, as often as this was done, to restore them by measurement; hence a system was invented, which was termed geometry. Thales, a philosopher who lived some 640 years before Christ, brought the science into Greece from Egypt, white, he had, it is related, gone in search of knowledge at rather a late period in life. He is said to have ap-plied a circle to the measurement of angles, and to have instituted various comparisons and relations between triangles by means of their proportions; one nave instituted various comparisons and relations between triangles, by means of their proportions; one particular point he discovered too, that all angles in a semicircle are right angles, which must be looked upon as an important discovery, when it is taken into consideration that the science was yet in its infancy. After Thales came Anaximander, who is said to have invented the state of the property and the speak and groups. geometrical charts, and the sphere and gnomen; next followed Anaximenes, who invented the sundial, and must thus have been acquainted both with astronomy and geometry. Pythagoras instituted the theory of regular solids; and under his school it was improved regular solids; and under his school it was improved gradually during the two centuries which clapsed after the introduction of geometry, until the school of Plato took it in hand. Plato seems to have had the bighest opinion of the science, and we read in the classics, that the inscription "Let no one ignorant of geometry enter here," was placed over the portals of his school. The theory of conic sections dates its birth from the Platonic achools and to the same source may be ascribed the uneary of come seemons dates its birth from the Fistonic schools, and to the same source may be secribed the beautiful theory of geometrical less, which is not only interesting from the hidden truths which it contains, but also from its importance in the solution of problems.

The school of Aristotle cannot be said to have done

Geometry

much towards the forwarding and improvement of geometry, although one of the writers of the same period has transmitted to us the only written accounts period has transmitted to us the only written a history of geometry in six books. The school of Alexandria is undoubtedly the first grand starting-point of geometry; it is justly celebrated in general history, but in mathematics its importance can hardly be over-rated. The sphool was founded shortly after the death of The sancor was founded sacrity after the death of Alexander, when the vast empire which had been built up by that conqueror was dismembered, and the greater portion of it fell to Ptolemy Lagus, who estab-lished his capital in Egypt. His wealth and encourage-ment, coupled with the disturbed state of their homes, induced many of the Greek philosophers to place themselves under his protection; and amongst these was Euclid, who is entitled to one of the highest places was mond, who is entitled to one of the nighest pieces in the history of geometry. Euclid's Elements are the foundation of the science, and all modern geometry is composed only of variations on his well-known theorems, axioms, and deductions. The writings of Archimedes are likewise most important; and although they are less studied in the present day, on account of their being less elementary than Euclid, yet they should be carefully conned by every mathematicisn, as they give a keen insight into the workings of ancient geometry -more so, in fact, than Euclid. The study of the mathematical sciences declined considerably in the 1st century of our era, but it regained its supremacy during the 2nd. Menelaus wrote on trigonometry and spherical geometry; and his work on the same reached us by means of a translation from the Arabic, which is in existence at the present day. Dr. Halley held Menein existence at the present day. Dr. Halley held Mene-lears in great esteem, and prepared a careful edition of his works, which was published in 1758. From the 2nd century up to the 8th, geometry again lan-guished considerably, and it was then taken up by the Arabians, as the Greeks had neglected it. It is from the Arabians, in fact, that some of the books of Euclid have been preserved for the benefit of science in general. The Participate has a learn against their conversions. The Persians have also possessed their geometricians, the most distinguished of whom was Nassir-Eddin al Tussi, who wrote a commentary on the great Euclid, which was published in Italy in the year 1590. The Hinduos appear to have been acquainted with some of the geoappear to have been acquained with some or ageo-metrical problems at even an earlier date than the Egyptians; but the evidence as to this is so obscure that much reliance cannot be placed on the fact. Geometry remained quiescent from the 8th century to the 17th, when it was again taken up with a similar seal as that by which it was prosecuted in the old Greek empire. Lucas Valerius, an Italian, was the first who gave it his serious consideration; and his re-searches led him beyond the timeworn pathway in first who gave it his serious consideration; and his researches led him beyond the timeworn pathway in which his predecessors had been contented to work. He selected a subject which Archimedes seemed to have forgotten; namely the centre of gravity in solida, and he carried out his purpose in a very satisfactory manner. In England, geometry, or the apirit of it, seemed now to have been imbibed; and Robert Record was the author of the first book on the subject printed in this country, entitled the "Pathway of Knowledge;" Edward Wright, another geometrician, was the inventor of the "Mercator's Chart." Kepler was the first of the moderns, however, who thoroughly understood and calarged his subject. He opened one of the unexplored pathways of science which had long been closed,—that of introducing the notion of infinity into science. The views of Kepler were eagerly adopted by Roberval and Cavalieri, and the carnest investigations of the three led to a fruitful harvest of discovery. The theory of tangents of Fermot, the differential calculus of Leibnitz, and the fluxional theory of Newton (see article on Fluxions), may be traced as consequences to the new views of Kepler. Guildin, a Jesuit, discovered the centre of gravity applicable to the measurement of solids formed by revolution; Galileo first suggested the cycloid; James Gregory was the author of the logarithmic ourve; and Leibnitz showed the two properties of the catenary. Before the time of Newton. pure security and Rephra were the only Newton, pure geometry and algebra were the only subjects on which mathematical students could exercise subjects on when mathematical students count exercise their genius; but his great and sublime discoveries opened a vast field for new studies. The fact of the orbits of the planets being in the form of ellipses,

naturally connected their motions with the theory of conic sections; and this is ably portrayed in Newton's "Frincipia." From repeated seets, the truth of this was fully established, and the theory became generally understood: whence this first step served as a ground-work of reasoning in all speculations on physics, and geometry and astronomy became even more closely allied than the ancients presumed them to be. The principles of functions and the calculus may be said to have eclipsed the geometrical method in the investigation of natural phenomena after Leibnitz invented the Differentials; and this was because of the intricacy of the latter. tials; and this was because of the intricacy of the latter, which unfits it for the more delicate calculations in the higher branches of mathematics. In concluding this brief sketch of geometry, before entering on the subject itself, it may be mentioned that Euclid is one of the best treatises which could be had on the elementary part of the subject; and after him comes Legendre's Geometry, which admits the student into the higher ranks of the science. All notions of geometrical mag-nitude are obtained by means of contemplating a body or solid, which is extended in three different forms; or solid, which is extended in three different forms; that is, in length, in breadth, and in thickness. The outside boundary of a solid which separates that particular portion of space which it occupies from space in general, is termed the surface, or superficies, that is, the external ares; and a surface cannot be considered as possessing any other qualities except length and breadth. Sometimes a surface is separated or divided into two or more parts within itself, by a boundary. This boundary is called a line, and has no divided into two or more parts within itself, by a boundary. This boundary is called a line, and has no other quality but length only. The termination of any line, which marks where it ends, or divides it into different portions, is termed a point, which possesses neither thickness, length, nor breadth. Solids, surfaces, and lines, therefore, are the subjects of geometrical investigation and discussion. There is no limit between the contract the surface and whatever to the number of these surfaces, solids, and lines which may be considered in this science. The lines which may be considered in this science. The elements of geometry, however, are restricted to a few, which include straight lines, circles, rectilineal plane figures, and their consequents, which constitute one branch of the science; and solids, bounded by planes, and the cylinder, the cone, and the sphere, all of which are formed by the intersection of planes, and which go to make up the other portion of the subject. Geometry is, consequently, divided into two branches, one of which treats of figures on a plane, the other of the formation and ramification of solids. 1st. Lines and figures on a plane.—Geometry treats on the properties and relations of quantities having or possessing the quality of extension; and such having or possessing the quality of extension; and such quantities are termed magnitudes, whilst extension is resolved into length, breadth, and thickness. A point has position, but no magnitude, and a line possesses only length: hence points and lines are closely allied; as the termination of every line, and the intersection of one line with another, must always be a point. A traight line, or right line, as it is termed in geometry, is always the shortest way from one point to another. Every line which is neither straight nor composed of straight lines, is a curve line. A superficies has only length and breadth; and, consequently, the extremities and intersections of superficies are always lines. A plane superficies is that in which any two points being taken, the right lines drawn between them lies wholly in that superficies. Every superficies which is neither having or possessing the quality of extension; and such taken, the right time drawn between them hes wholly in that superficies. Every superficies which is neither a plane, nor composed of plane superficies, is termed a curve superficies. A solid has length, breadth, and thickness; hence the boundaries of all solids are superficies, and the contiguous boundary to two solids which are connected is also a superficies. A plane rectifined angle is the inclination of two straight lines to one another which must to one superficient. angle is the inclination of two straight lines to one another, which meet at one point, but are not in the same straight line. The point of meeting between them is called the vertex of the angle. Angles, in common with other quantities, admit of addition, subtraction, multiplication, and division. When one straight line erected on another straight line makes the adjacent angles equal to one another, then each of the angles thus formed is a right angle, and has 90 degrees; the line which makes them with the base is termed the perspendicular. An obtuse angle is that which is greater than a right angle; and an acute angle is less than a right angle. Parallel straight lines, which are

in the same line, are such as, when produced, can never meet. A plane figure is a plane terminated everywhere by lines; if the lines are straight, the space they inclose is termed a rectifined figure, or polygon, and the lines themselves are termed the perimeter of the same. When this polygon has three sides (the least number it can possibly have), it is called a triangle; when four, a quadrilateral; when five, a pentagon; and so on. An equitateral triangle is hat which has three equal sides; an isosceles trangle as two sides count; and a scalese triangle has as two sides equal; and a scalene triangle has il three sides mequal. A right-angled triangle has a right angle, and the side of the triangle opposite this angle is called the hypothenuse. An obtuse-angled triangle has an obtuse angle, and an acute-angled triangle has an acute angle. Among quadrilateral triangle has an acute angle, and an acute-angea triangle has an acute angle. Among quadrilateral figures, a square is that which has its four sides all equal to one another, and all its angles right angles. A rectangle has all its angles right angles, but its oppo-site sides only are equal. A rhombus has all its sides equal, site sides only are equal. A rhombus has all its sides equal, but its angles are not right angles. A parallelogram, or rhombuid, has its opposite sides parallel and equal; and a tropezoid is a figure which has only two of its opposite sides parallel. The straight line which joins the vertices of two angles which are not adjacent to each other is called a diagonal. A polygon which has all its sides equal, is called an equilateral polygon; and it has not a real lead an equilateral polygon. its suces equal, is called an equitateral polygon; and it he angles are all equal, it is called an equiangular polygon; if both the angles and the sides of the polygon be all equal, it is called a regular polygon. With regard to the terms used in geometry, an axiom is a proposition the truth of which is evident at first sight to the observer; a theorem is a truth which has been demonstrated or reasoned; and a problem is a question proposed which requires solution; a lemma is only a subsidiary truth employed in the solution of a problem or the demonstration of a theorem; a corollary is a consequence which follows the theorems of one or several propositions or problems solved; a scholium is a remark made upon one or more preceding propositions, and it tends to show the application, the restriction, or the extension of the same; an hypothesis is a supposi-tion made in order to effect more easily the demontion made in order to enect more easily the demonstration or enunciation of a problem or theorem; and, lastly, the term proposition is applied generally to problems, theorems, and lemmas. The signs used in geometry are the same as those of sigebra. The fundamental axioms on which the science is based may be sufficiently as the side of the s indamental axioms on which the science is based may be said to be six in number. 1st. Two quantities, each of which is equal to a third, must be equal to one another.—2nd. The whole of anything is greater than a part of the same.—3rd. The whole of anything is always equal to the sum of its parts or subdivisions.—4th. Only one straight line can be drawn between any two points.—5th. Two magnitudes, whether they are lines, surfaces, or solids, are equal, if, when applied to one another, they exactly coincide, or fill the same space that is.—6th. All right angles are equal to one another. The application of these axioms, and the foundations of others, are laid down in the first and second books; whilst the proportions of the circle cocupy the third and fourth books of Euclid's Elements, and may be thus summed up:—A circle is a plane figure contained by one line, which is called a circumference; and the characteristics of the figure are such that all lines drawn from its centre, to its circumference are equal. These lines centre to its circumference are equal. These lines are called radii, or semidiameters; and the straight line which passes through the centre, and is bounded at either end by the circumference, is termed the diameter, and it divides the circle into two equal parts. An arc is any portion of the circumference of a circle which is any portion of the circumference of a circle which is separated by a chord, or straight line, which does not pass through the centre. A segment of a circle is the figure contained by an arc and its chord; if the chord passes through the centre, then the segment will be a semicircle. A sector is that part of a circle contained by an arc and two radii, drawn one to each extremity of the arc: if the radii are at right angles to one another, then the sector is said to be a quadrant. A straight time is said to be applied in a circle, when its extremities are in the circumference of the same. A reactilineal figure is inversibed in a circle, when the verrectilines figure is inscribed in a circle, when the vertices of all its angles are on the circumference. A straight line is said to be a tangent to a circle, when it

meets it in one point only; and the point of meeting is styled the point of contact. A polygon is said to be described or circumscribed about a circle, when all its circle is eaid to be incle; and in this case the circle is eaid to be increased in the polygon. The drawing of tangents and chords are the most important propositions connected with the circle, and these are fully shown by Euclid. Proportion is, however, the greatest of attributes which belong to plane figures. In comparing two quantities of the same kind, we are greatest of attributes which belong to plane figures. In comparing two quantities of the same kind, we are led, in order to have a just idea of their relative proportion, to inquire how often the less is contained in the greater magnitude. When one contains the other a certain number of times, without leaving any remainder, the greater quantity is said to be a multiple of the less, and the latter is a point of the former: equimultiples are multiples which contain similar quantities a similar number of times, and are consequently equal to one another. The relation between any finite magnitudes is termed exite. and the two macroitudes comparitudes is termed exite. and the two macroitudes comparitudes is termed exite. to one another. The relation between any name mag-nitudes is termed ratio, and the two magnitudes com-pared, are the terms of the same; the first being called the antecedent, and the second the consequent of the ratio. The terms of an equal number of ratios are called proportionals. Thus, if four quantities, A, B, C, and D, are taken, which are proportionals, A is said to be to B as C is to D; whence, A divided by B is aqual to C divided by D; and so on. The axioms with respect to proportion are three in number. 1. Equal quantity to proportion are three in number. 1. Equal quantities have the same ratio to the same quantity, and the same quantity has the same ratio te equal quantities.—
2. Quantities having the same ratio to the same quantity, or to equal quantities, are equal to one another.—
3. Ratios equal to one and the same ratio, are equal also to one another. If four quantities are said to be proportionals by inversion, it is interred that the fourth is to the third as the second is to the first. By composition, is when the sum of the first and second is to the second as the sum of the first and second is to the fourth. By alternation, when the first is to the third as the second is to the fourth. By division, when the difference of the first and second is to the second as the difference of the hird and fourth is to the second as the difference of the third and fourth is to the fourth. By conversion, when the first is to the difference of the first and second as the third is to the difference of the third and fourth; and lastly, by mixing, when the sum of the first and second is to their difference as the sum of the third and fourth is to their difference. doctrine of proportion in Euclid's fifth book applies doctrine of proportion in Euclid's fifth book applies alike to commensurable and incommensurable quantities; but for the sake of simplicity, it is generally taken in the former sense Equivalent figures are such as have equal surfaces: thus a circle may be equal to a square, and so on, although the figures are very dissimilar. The lastimaportant branch of the geometry of plane figures, is this quadrature of the circle, on which depends the discovery of the relation between the diameter and the circumference of a circle, which was said to have been known by the Chinese long before the diameter and the circumsterence of a circle, which was said to have been known by the Chinese long before the Christian era. The proportion between the circumsterence and diameter of a circle was found by contrasting the proportion between the sides of an inscribed and circumscribed polygon about a circle; it being found that the areas of these differed so little, as to give very nearly the circumference of a circle; from which it was deduced, that if the diameter equals the figure 1, the circumference will be 3:1415926, equals the figure 1, the circumference will be 3 1415226, which is near enough for all practical purposes, although, for astronomy, it is necessary to have a larger number of places of decimals. The second part of the science of geometry concerns that relating to solids. A solid has been already defined, as that which possesses length, breadth, and thickness, and in the latter characteristic, comprising its difference from a plane figure. A prism is a solid contained by plane figures, of which two opposite ones are equal, similar, and parallel, and the others are parallelograms. The distance between the bases of a prism is termed its dititude. A cube is a rectangular parallelopiped, contained by six equal squares. A pyramid is a solid contained by several planes which meet in the same point, and which terminate at the anterior extremity in a polygonal plane. An imat the anterior extremity in a polygonal plane. An important theorem in solid geometry is, that the solidity of any parallelopiped, or, in general, of any prism, is equal to the product of its base and its altitude when multiplied together. Buclid treats on the elementary

### George, St.

portions of plane and solid geometry in his sleventh book, which contains most of the propositions and theorems on the subject. The highest branch of geometry, although perhaps not the most useful to engineers, is undoubtedly that which treats of the cylinder, the line, and the sphere. A cylinder is a solid figure described by the revolution of a right-angled parallelogram about one of its sides which remains fixed. The axis of the cylinder is the fixed straight line or side about which the parallelogram revolves; and the bases are the spircles described by each extremity of the parallelogram. A cone is a solid figure described by right-angled triangle about one of the sides containing the right angle, which remains fixed. A sphere is a solid figure produced by the revolution of a semicircle about its diameter, which remains fixed. Similar cones and cylinders are such as have their axes and diameters of their bases equal or proportional. In order to estimate the curvature of any surface at a proposed point, it may be observed, the surface of a sphere cannot be assimilated with the curvature of any surface whatever; because in the sphere the curvature is uniform about the same normal, whereas in surfaces in general this is far from being the case. The say surface waterer; but the same normal, whereas in surfaces in general this is far from being the case. The mode of proceeding in such cases must, therefore, be to imagine several planes drawn through the normal at the point under consideration, in order to calculate the radii of curvature of each of those sections at that radii of curvature of each of those sections at that point, and, by comparing them, to judge of the greater and lesser curvature in those directions about the point, as well as towards what points the curvature is turned; for, curved surfaces contiguous to any point are situated partly below and partly above the tangent plane drawn to that point. In making different planes pass through the same point of a surface, so that some contain the normal to the surface and some do not it will be found that the radii of curvature. do not, it will be found that the radii of curvature relative to that point, both of the normal and oblique sections, bear remarkable relations to one another. independently of the particular form or curvature of the surface. It would be impossible in the proportions of the present work to give even the rudiments of analytical geometry of dimensions, or to deduce the various propositions, theorems, and applications of Euclid's formulas, which, did space permit, might readily be done. The reader is referred for more consistent of the proposition of the arbitrate to Tabletick to T readily be done. The reader is referred for more explicit information on the subject to Euclid's Riements, Newton's Principia, Hutton's Mathematical Tracts, Legendre's Riements de Géométrie, Hymer's Analytical Geometry, and Kopler's works, which enter at large on both divisions of geometry, both practical and theoretical. (See also separate articles on CONIC SECTIONS, ELLIPSS, FLUXIONS, GRAVITATION, &c.) GROEGE, ST., jorje, saint, the patron saint of England, was born in Epiphanis, Cilicis, or, according to some accounts, in Cappadocia; and was, during the latter years of his life, bishop of Alexandria. Some historians, however, relate that St. George was a soldier in the service of the emperor Diocletian, and that he suffered martyrdom along with many others on

# Gerhardt's Notation

world, but the greater number are found at the Cape of Good Hope. There are four genera and about 500 species, many very remarkable for the beadty of their flowers

flowers.

Grankium, je-rai'-ne-um, in Bot., the Crane's-bill, the typical gen. of the nat. ord. Geraniace. The species are chiefly European plants, in many cases being mere weeds of no interest, and in others being extremely showy border-flowers. The favourite plants called geraniums do not belong to this genus, but to the genus Pelargonium (which see). The root G. maculatum is a powerful astringent, and is much used medicinally in North America, where it is called alumnout. G. parviforum produces edible tubers, which are known in Van Diemen's Land under the name of native carrots. native carrots.

native carrots.

GERANUM OIL. (See ANDROPOSON.)

GREFILOON, or JER-FILCON, jer'-fawl-kon (Fr. gerfaut) (Fulco Gyrfulco), a species of falcon, considered as the boldest and most beautiful of the tribe. In size it approaches closely to that of the caprey. It general colour is brownish-grey, of varied tints above and white beneath, with brown longitudinal spots. The tail is crossed with a number of deeper and lighter bands, and the bill and legs are usually of a pale blue or yellowish colour. Three varieties of the ger-falcon are

GER-FALCON.

historians, however, relate that St. George was a soldier in the service of the emperor Diocletian, and that he suffered martyrdom along with many others on account of his embracing Christianity. After the crusades, the fame of St. George, who was termed by the Greeks "victorious," spread so much that, in the reign of Edward III, he became the patron sain to England. In order to enhance his popularity among the illiterate, the fabulous story of St. George and the Dragon was concoted as a reason for his canonization. Georgics, je-or-jiks (Gr. georgika, things relating to husbandry), is the title of a poem on agriculture and rural economy, by Virgil, in four books. It is regarded as the most perfect of his works, and displays an intimate knowledge of the subject.

General of the crame's-sil fam., a nat. ord. of Diocyledones, sub-class Thalamifors. Herbs or shrubs with simple leaves, membranous stipules, and articulated swollen joints. Flowers usually symmetrical; sepals five, imbricated; peats twisted in astivation; stamens generally comernate monadelphous. Fruit consisting of five carpois, stacched by means of their styles to an elongated axis or carpophore, from which they separate when ripe from below upwards by the curling up of the styles. Seeds, one in each carpel, exalbuminous; embryo convoluted. Some plants of this order are distributed over various parts of the

### Gerhardt's Notation

# it will be seen that there is a discrepancy between the specific gravities and the equivalents of some few bodies. This will be plain from the following examples :

	Equiv. Spec. Grav.
Hydrogen	
Oxygen	8 15.9
Bulphur	
Chlorine	35.5 34.9
Bromine	90 70-8

To remove this anomaly, M. Gerhardt doubles the To remove this anomaly, M. Gernard coules the equivalent numbers of exygen, sulphur, carbon, selenium, and tellurium, on the assumption that equal volumes of elementary gases and vapours contain the same number of atoms when compared under similar consume number of atoms when compared under similar consumers. sume numer of atoms went computed unter sintar con-ditions of heat and pressure; which is equivalent to saying that an atom of oxygen weighs sixteen times as much as an atom of hydrogen, because a cubic foot of the former gas weighs sixteen times as heavy as a ou-bic foot of the latter. According to this new system, therefore, the equivalents of oxygen, carbon, sulphur, selenium, and tellurium are doubled; and in most chemical books these doubled equivalents are indicated by a line drawn through the letter; thus—eeg p. 5. A few compounds, formulated according to both systems, are given below; but, for convenience, the new equivalents are printed in italies:—

•	Old Formulæ.	New Formulæ.
Water Potash Oxide of silver Alumins Sesquioxide of iron Chloride of potassium Sesquichioride of alumina Hydrochlorio acid Bulphide of potassium Cyanogen Cyanogen Carbonic oxide	HO KO AgO Al.O. Fe.O. KCI Al.CI. HCI KS O.N CO	H.O Ag.O Al.O. Fe.O. KCl Al.Cl. H.Cl. H.Cl. CN CO

Besides the change in the equivalents described above, Gerhardt revived and fully carried out a theory of the constitution of acids and salts, first propounded by Sir Humphrey Davy. According to the present theory, as first started by Lavoisier, Berzelius, and others, nitrate of silver would be formulated thus:—AgO, NO.; being looked on as a compound of nitric acid and oxide of ailver; but, on comparing this salt with its corresponding haloid, chloride of silver, a disorepancy occurs, which vanishes, if we consider nitric acid, as existing in nitrate of silver, to consist of NO, instead of NO. From numerous other accounts. existing in nitrate of silver, to consist of NO<sub>a</sub> instead of NO<sub>a</sub>. From numerous other anomalies, occurring chiefly in organic bodies, Gerhardt came to the following conclusions:—1. That every uncombined soid necessarily contained one of more equivalents of hydrogen.—2. That the bodies hitherto regarded as dry soids possessed no acid properties until united with hydrogen and oxygen.—3. That salts were formed by the substitution of one or more atoms of hydrogen. by the substitution of one or more atoms of hydrogen, by one or more stoms of a metal, or some substance acting as such. Thus, the bodies known as NO<sub>2</sub>, SO<sub>3</sub>, and CO<sub>3</sub>, are neutral and inert, until united with an equivalent of water, when they form respectively nitrie, sulphurio, and carbonic acids.

	Old view.	New view.
Nitric scid	NO.	HNO.
Bulphuric acid	80,	HSO.
Carbonic acid	co.	HCO.

This brings the haloid and oxygoid salts into perfect harmony, both being regarded as acids in which the hydrogen is replaced by a metal.

$$HCl + K = KCl + H$$
  
 $HSO_4 + K = KSO_4 + H$ 

or, in other words, the sold is regarded as the nitrate sulphate, or carbonate of hydrogen, and the sait formed, as the nitrate, sulphate, or carbonate of the metal. Hence the terms nitrate of potassium, sulphate of sodium, and carbonate of ammonium, as used by Gerhardt's followers, instead of those in ordinary use.

### German Catholics

German Catholics

Gerhardt also originated the system of arranging compounds according to types, and sully worked out the theory of the formation of all bodies by the substitution of one element or group of elements by others of a similar character. (See Salzs, Substitution Tenony, Types,—Ref. Fowne's Manual of Chemistry, 8th edition, Appendix; Odling's Messual of Chemistry.

German Catholics, jer's make kith-o-liks, is the name of a religious sect which has recently been formed in Germany, by secession from the Roman Catholic church. It originated in a proclamation of a special pilgrimage and service by Bishop Arnoldi, of Treves, to the holy coat of that city, to be accompanied by remission of sins. This proceeding called forth a letter from Johannes Ronge, an excommunicated priest of Silesia, dated 1st Ootober, 1844, characterising it as an idolatrous festival, and calling upon the bishop to suppress it. A short time before, another Catholic priest, Johann Czerski, had seceded from the Romish church, and attempted the foundation of an independent Christian congregation. The letter of Ronge met with many sympathizers, and czerski, a number of congregations sprang up in a very short time. calling themselves German Catholics. The having been effected between konge and Czerski, a number of congregations sprang up in a very short time, calling themselves German Catholics. The "Confession of Schneidemühl," drawn up by Czerski, Oct. 19, and presented to the government Oct. 27, 1844, rejected as unscriptural, and as merely human ordinances, the reception by the priests alone of the Lord's supper in both kinds; the canonization and invocation of the saints; indulgences and purgatory; fasting; the use of the Latin language in divine service; mass and vespers; the ceilibacy of the priests; the prohibition of mixed marriages; the supremsey of the pope, and other points. They declared themselves determined to sever their connection with the pope, to receive the Lord's supper in both kinds, and to recognize the Bible as the only rule of faith. They retained the seven sacraments and the mass, which they celebrated in the vernacular tongue. The "Confession of Breslan," which set forth the views of retained the seven sacraments and the mass, which they celebrated in the vernacular tongue. The "Confession of Brealau," which set forth the views of Bonge, proceeded farther than that of Schneidemühl,—claiming free investigation of the Bible, and freedom of belief for every individual member. It regarded as essential doctrines only,—belief in God, the creator and governor of the world; in Jesus Christ, as having, by his doctrine, his life and death, redeemed men from sin and misery; and in the influence of the Holy Spirit upon earth. Of the sacraments of the Catholic church, it retained only baptism and the Lord's supper. A council met at Leipsic on the 22nd of March, 18-25, in which Ronge, Czerski, and the delegates of twenty congregations, took part; and a new creed was adopted, based principally upon the Confession of Breslau. After that time the principles of German Catholicism spread very rapidly, being of German Catholicism spread very rapidly, being adopted not only by many Roman Catholic priests, but adopted not only by many Roman Catholic priests, but also by many Protestant clergymen and laymen. At the end of 1845, they comprised about 300 congregations. They, however, met with much opposition from the various governments, and many vexatious restrictions were imposed upon them in Prussis, Saxony, Bavaria, and other states. A more serious source of disquiet, however, arose among themselves. It has been seen that the tendency of Czerski was towards the doctrines and ritual of the Church of Rome; Ronge, on the other hand, approached towards rationalism. A series of dissensions, in this way, arose among the body, which was very prejudicial to their progress. An attempt was made to unite both parties in an assembly at Bawicz, in the month of February, 1846, in which Czerski, Ronge, and others took part; but it had not the desired effect. The congregations sympathizing with Czerski met at Schneidemühl in the month of July in the same year, in order to effect a closer organisation among them, in order to effect a closer organisation among them selves; but, from the great differences of opinion that prevailed among them, they were unable to come to any agreement. Nor were the followers of Ronge more successful in their attempts to effect the same object. A council was held at Berlin, in May, 1847, attended by deputies from 151 congregations, and new efforts were made to accomplish a union of the two parties, but with little better success. The revolution of 1848 was favourable to the German Catholics,

and generally led to the removal of some of the civil restrictions to which they were subjected. A conference was held at Kothen in 1850, at which an alliance was proposed with the free congregations which had formed themselves by secession from the Protestant churches; and a diet was fixed for 1852; but it did not meet. Since that time German Cathotrocerent controller; and a une was ment to 1992; but it did not meet. Since that time German Catholicism has been on the decline, partly on ascount of internal dissensions, and partly from oppressive measures adopted against them by the governments. Many congregations have been disbanded, while others have gone over in a body to the Protestant church.

A conference was held at Gotha, Sept. 10, 1858, at which, however, only forty-two representatives were

Present.
GERMAN LANGUAGE AND LITERATURE (Ger. Deutsche Sprache und Literatur).—The German language is a branch of the Indo-Germanic class of languages, which separated from the parent stock at a very early period. The Germans called their language Deutsch or Teutsch, The Germans called their language Deuteck or Teuten, from their aucestors, the Teutons. In its widest sense the Teutonic consists of two branches,—the Northern, or Scaudinaviau, and the Southern, or German. The latter has three subdivisions,—the Rastern, or Gothic, the High German, and the Low German. The Gothic is the carliest of these of which we possess any literary remains, there being still in existence portions of a translation of the Bible into Gothic made by Bishop Italia is the 4th cantury, but we possess puthing of Ulfiles in the 4th century; but we possess nothing of the High or Low German till the 7th century. Hence many persons have been led to regard the Gothic as the original source of the German; but, according to Max Müller, the grammatical differences between the max Muller, the grammatical differences between the two are of such a nature as to show that this was impossible. "There never was," he says, "a combron uniform Teutonic language, nor is there any evidence to show that there existed at any time a uniform High German or Low German language, from which all High German and Low German dialects are respectively derived." The Gothic language died out in the 9th century. The Low German (Platt Deutsch) comprehends many dislects in the north or lowlands of German Country and Plantic Street Country and Pl many, as well as the Friesian, Dutch, and Flemish dis-lects. The oldest literary document of Low German on the continent is the Christian epic the "Heljand" off the officer of Saviour), which is preserved to us in two MSS.
of the 9th century. There are traces of a certain amount
of literature in Saxon or Low German from that time onward, through the middle ages, up to the 17th cen-tury, but little of that literature has been preserved; tury, but little of that literature has been preserved; and after the translation of the Bible by Luther into High German, the fate of Low German literature was sealed. High German (Hoch Deutsch) has been the literary language of Germany ever since the days of Charlemagne. Its history may be traced through three periods,—the Old High German, extending from the 7th to the 12th century; the Middle High German, from the 12th century to the time of Luther; and the New High German, from Luther down to the present time. In the present day there are various dialects of the German spoken in different parts of the present time. In the present day there are various dislects of the German spoken in different parts of the country; as the Swabian, Bavarian, Franconian, Saxon, &c., (See Müller's Lectures on the Science of Language.) The earliest existing monument of German literature is the translation of the Bible into Gothic by Ulflas, is the translation of the Bible into Gothie by Ulfilas, already alluded to. After the Gothie language ceased to be spoken, nothing was known of this work until towards the close of the 16th century, when a portion of it,—namely the four Gospels, was found in the abbey of Werden. The letters are in silver upon purple veilim; whence it is called the Codex Argentess, and it is now preserved in the library of Upsala. Afterwards, in 1616, the Epistles of St. Paul, of the same work, were discovered by Cardinal Mai and Count Castiglioni in the monastery of Bobbio, in Lombardy Of the translation of the Old Testament only a few lines remain. The earliest literature of Germany is known to us only by report or tradition. According lines remain. The earliest literature of Germany is known to us only by report or tradition. According to Tacitus, the Germans celebrated in songs, which were old even in his time, the praises of their national deity Tuisco, and his son Mannus, as well as the deeds of their great heroes. When the nations began to migrate, heroes of greater and greater remown march into the scene of song, and the historic forms of Attile, Theodoric, Günther, and others, appear. The two

most ancient German poems are the "Lay of Hildebrand and Hadabrand" and the Prayer of Weissenbrun, which belong to the 6th century. Many of the legends of this period were afterwards embodied in the lay of the "Nibelungen," the most celebrated production of German mediawal poetry. The introduction of Christianity exercised an important change in the early literature of Germany. The Latin language early literature of Germany. The Latin language came to be that of the church, the court, and the law. came to be that of the charten, the court, and the law.

A kind of religious poetry, after the model of the Roman poets, was introduced in place of the ancient heroic and mythical songs, and was fostered by the court as well as by the clergy. Charlemagne, indeed, was fondly attached to the ancient lays of his fatherland, was londly actsoned to the another to be made; but his successor, Lewis the Pious, looked upon everything German as heathenish: and the consequence was, the almost total destruction of every poem which bore a special mythological character. The "Heljand," a special mythological character. The "Heljand," a poem giving the life of Christ, was written at the in-stance of Lewis the Pious in the 9th century, and stance of Lewis the Pious in the 9th century, and is one of the noblest productions of poetic genus that has ever appeared. Thirty years later appeared another sacred poem, known as the "Krist," composed by Otfried, a Benedictine monk of Weissenburg. Another poem of this period is the so-called "Ludwigs-lika". lied," a poem in honour of the victory of the Frankish king, Lewis III., over the Normans in 883. The other poetical remains of this period are chiefly of a religious poetical remains of this period are cheen of a religious nature, and, together with the contemporary prose literature, are not worthy of notice. Germany, by losing its French and Italian provinces, had become Germany again; and a desire to cultivate the national literature again began to manifest itself. The monks of St. Gall, Passau, and other places, translated some of the German epics into Latin verse; such as the poem of the "Nibelungen," of "Walther of Aquitaine," and of "Ruodlieb," the last two of which have been pre-served and published. The stories of the for, the bear, sad other animals, so peculiar to German poetry, attracted the attention of the monks; and it is owing to their Latin translations that this curious style of poetry can Latin translations that this curious style of poetry can the 10th century. The 11th be traced back so far as the 10th century. The 11th century presents almost an entire blank in the history of German literature. The old High German had become a literary language chiefly through the efforts of the clergy, and its character was pre-eminently clerical. The Crusades, however, put an end to the clerical element in the literature of Germany. The chivalrous emperors of the Hohenstaufen dynasty formed a new emperors of the Hobenstauten dynasty formed a new rallying-point for all national sympathies; and the interest of the people was with the knight, not with the priest. Poetry changed hands, and the royal courts and knightly eastles offered a new and more genial home to the poets of Germany than the monas-teries of St. Gall and Fulds. Middle High German, teries of St. eat and Finis. Infinish High expensions the language of the Swabian court, became the larguage of poetry, and the poets took their inspiration from real life, though they borrowed their models from the romantic cycles of Brittany and Provence. The stories of Arthur and his Knights, of Charlemagne, of Achilles, Eness, and Alexander, imported by French and Provenous knights, served them as their first and Provences Enights, served them as their area models; and while foreign influence is seen in every branch of German poetry at this time, yet nothing can be more different than the same subject, as treated by French and German poets. The German Minnesanger, in particular, were far from being imitators of the Trouvères or Troubadours. Poets made bold for the strict time to express their own feelings, their joys, and sufferings, and epic poetry had to share its honours with lyric songs. The poetry which flourished at the castles was soon adopted by the lower ranks, and the poems of the "Nilcolungen" and "Gudrun," as we now had been added to the time had been added to the possess them, were composed at that time by posts who possess them, were composed at that time by posts who took their subjects, their best thoughts and expressions, from the people; but imitsted the language, the metre, and the manners of the court poets. Thus there are two kinds of poetry of this period,—the national, or people's poetry, the production of strolling materies; and the art poetry, or that of the courts, composed chiefly by kings and courtiers. Many of the poets were nobles by birth, several of them prinoes. Among the distinguished poets of this period, are Heinrich von Veldecke, Hartmann von Aue, Wolfram

von Eschenbach, Gottfried von Straaburg, and Kon-rad von Würzburg. The fall of the Swabian dynasty of the house of Hohenstaufen, in the latter half of the 13th century, was the death-blow to German chivalric poetry. Lysic poetry continued to flourish for a time; but it degenerated into an affected sentimentality and anworthy idolatry of the ladies. Didactic poetry, how-ever, began to be cultivated with some degree of success. The middle classes, the burghers of the free towns of degrees were new heripping to rise into power of Germany, were now beginning to rise into power, and poetry again changed hands. It now passed from the abodes of princes and knights to the homes of burghers and the workshops of artisans; and instead of the Minnesinger, we have the Meistersinger, and their strains were more subdued, practical, and homely. Poetry became a trade, like any other, and guilds were Foetry became a trade, like any other, and guilds were formed, consisting of master-singers and their apprentices. Heinrich Frauenlob is called the first Meistersänger, and during the 14th, 15th, and 16th centuries, new guilds or schools were formed in all the principal towns of Germany. The poetry of the 14th and 15th centuries is interesting historically, but is not otherwise of much value. The best songs of the period are those of Halbauter and Veif Weber, celebrating the victories of Switzerland over Austria and are those of Halbauter and Veit Weber, celebrating the victories of Switzerland over Austria and Burgundy. Attempts were made to revive the chivalric poetry of the Crusades, both in the beginning and towards the close of the 15th century, but without success. In the 13th century, prose literature begins to flourish, and several local chronicles appear,—as well as works on jurisprudence, and some sermons. In the 14th century, Germany possessed several mystic theologians, as Eckart and Tauler, men of clear intellect and energy of purpose, whose sermons and writings contributed to pave the way for the Reformation. In 1373, the first complete translation of the Bible into German was made by Matthias of Beheim. An important event in this century, in its general influence upon the future progress of German literature, was the establishment of the university of Prague, followed soon after by universities in almost all parts of Germany. The 15th century was rich in scholars, but poor in men of genius or strong thinkers. The invention of the art of printing was a reformation in this century, the hence the of which were abited. genius or strong thinkers. The invention of the art of printing was a reformation in this century, the benefits of which were chiefly felt by the great masses of the people. It extended to them the privileges which had previously been confined to the rich. Between 1470 and 1500, several thousand editions of books were printed in Germany. The 16th century introduces, along with the Reformation, a new era in the history of the literature of Germany. Luther's translation of the Bible is so pure in language, and so beautiful in style, that it is still regarded, even in the present day, as a model of elegant expression. The present day, as a model of elegant expression. The religious quarrels which agitated Germany during the religious quarrels which agitated Germany during the 16th century gave to literature a theological direction, and the first scholars of that time were more or less engaged in religious controversy. Prominent in this class, after Luther himself, ratuad Zwingli, Johann Arnd, Bugenhagen, Bullinger, Melanchthon, and Ulrich von Hutten. Some of the best poets of this period, as Boban Hessius, composed their poetry in Latin; and, indeed, there came out from the universities a tendency to exalt the Latin above their mother tongue, which was very prejudicial to the latter. The period before and after the Reformation was especially furtiful in satirical and allegorical works. One of the tongue, which was very preparation was especially period before and after the Reformation was especially fruitful in satirical and allegorical works. One of the most remarkable of the former class was the "Ship of Fools" (Narrenschiff), by Schastian Brant, a metrical satire on the follies of the age; and which was afterwards imitated by Thomas Murner, in his "Narrenswards in the Murner was Johann Fischart, the author of numerous works; among which may be mentioned "Flohatz," a remarkably witty poem on fleas; and a romantic poem, "Das ably witty poem on fleas; and a romantic poem, "Das ably witty poem on fleas; and a romantic poem, "Das ably with the German among which may be mentioned "Flohatz," a remarkably witty poem on fleas; and a romantic poem, "Das glückhafte Schiff." He has been called the German Rabelais. Of the popular songs (Volkshieder) of this period, some have been much admired. The works of Hans Sacha, the poet and cobbler of Nuremberg, display a very remarkable degree of fertility, liveliness, and humour. A great poet, in the strict sense of the word, he was not; but he possessed an uncommon talent for mastering any given subject, and he was the

most popular poet in Germany during that century. His works are numerous, and in all apples of composi-tion, from the most tragic touch of feeling to the most popular poet in Germany during that century. His works are numerous, and in all tytes of composition, from the most tragic touch of feeling to the most comic turn of thought. This period produced several distinguished scholars and men of science; among whom may be mentioned Melanohthon, Camerarius (classics and philology), Cornelius Agrippa, Theophrastus Paracelaus (mystical philosophy and natural history), Copernicus (astronomy), Leonhard Fuchs (botany and medicine), Corrad Gesner (botany and zoology), and Agricola (mineralogy). Towards the en of the 16th century, everything seemeddrifting back into the middle ages; and then came the Thirty Years war, which, in its consequences, was most disastrous to Germany. The physical and moral vigour of the nation was broken. We meet with no trace f originality, truth, taste, or fealing in the poetry of that period, except, indeed, lin the sacred poetry, many of the hymns of Paul Gerhard being still sung in the Protestant churches of Germany. As auterly opposed to nationality or originality. Opitz, the founder of the so-called Sileaian school, is the true representative of the classical poetry of the 17th century. He was a scholar and a gentleman, most correct in his language and versification, never venturing on ground which had not been trodden before by some classic poet, whether of Greece, Rome, France, Holland, or Italy. Literary societies were formed at several of the courts of Germany, professedly for the improvement of the language and poetry of the country, after the model of those of Italy; but they were mere silly imitations, and produced little good. The "First Silesian school" is represented by men like Opitz and Weckherlin, and is characterized as pseudo-classical. It was imitated in the north of Germany by Simon Dach, Paul Flemming, and a number of less-gitted poets, who form the "Königaberg school." The chief heroes of the "Second Silesian school" is represented by men like Opitz and Weckherlin, and is characterized as pseudo-classical. It was imitat and a number of Isss-gitted poets, who form the 
"Königsberg school." The chief heroes of the 
"Second Silesian school." The chief heroes of the 
"Second Silesian school." The Hoffmannwaldau and 
Lohenstein, whose compositions are more ambitious, 
bombastic, and full of metaphors than those of Opitz; 
but are also more disappointing. There were some 
independent poets who kept aloof from either of these 
schools, as Friedrich von Logan, Andreas Gryphins, 
and Moscherosch. Among the other works of this 
period, we may mention the "Simplicissimus," a novel 
giving a lively picture of German life during the 
Thirty Years war; the patrictio writings of Professor 
Schupp; the historical works of Paffendorf; the 
pietistic sermons of Spener and of Franke, the founder 
of the orphan school at Halle; Professor Arnold's 
ecclesias ical history; the first political pamphlets of 
Professor Thomasius; and among philosophers, Jacob 
Boehme at the beginning and Leibnitz at the end of the 
entury. The 18th century was marked by a revolution 
in the literature and modes of thought in Germany. 
Johann Christoph Gotteched, professor of eloquence at 
Leipsic, in the early part of this century, exercised great 
power as a critic, and was the means of defeating the 
Second Silesian school. He was, however, an advocate 
of French models in art and poetry; and it was 
through the opposition which he roused by his Gallomains, t at German poetry was at last delivered from 
the trammels of that foreign school. Gottsched and 
his friends at Leipsic were opposed by Bodmer and

his frien named, we're Hagedorn of Hamburg, whose fables and songs have immortalized him in Germany; and Albert von Haller, the physiologist, remarkable also as a writer of descriptive and didactic poetry. During this literary stringgle, the great names of German poetry sprang up, — Klopstock, Wieland, Lessing, Herder, Goethe, and Schiller. Klopstock's "Messiah" made a profound impression by its mystic, devout, and rapturous faith, as well as a work of art. The fashionable

and elegant portion of society was attracted by the semi-Grecian, semi-Parisian muse of Wieland. But it was reserved for Lessing to give a new direction to German literature. He established a new school of criticism, and exerted a powerful influence upon the progress of the drama, by unfolding, for the first time, to the German mind, all the beauty, originality, and vigour lof Shakespeare. His tragedy "Emilia Galotti," his comedy "Minna von Barnhelm," and his philosophical drama "Nathan der Weise," are models of dramatic composition. Herder, a man of vast learning as well as a noetic genius, exerted a strong influence instic composition. Herder, a man of vast learning as well as a poetic genius, exerted a strong influence upon the poets of his time, and contributed powerfully to promote the study of Oriental poetry, as well as the ancient popular songs of different nations. The crowning work of his life is his "Ideen zur Philosophie der Geschichte der Menachheit." Another great impulse was given by Winekelmann, whose writings on the remains of ancient art modified all the old theories of the beautiful. Goethe came forward in 1773 with his "Goetz von Berlichingen," which was greeted as the commencement of an entirely new 1773 with his "Goetz von Berlichingen," which was greeted as the commencement of an entirely new period in German dramatic literature. In 1781 appeared Schiller's first piece, "Die Räuber" (the Robbers), followed by "Fiesec" and "Cabale and Liebe." These impassioned tragedies gave a new impulse to the literary excitement. His "Don Carlos" (1784) shows greater moderation, and opens a long series of tragedies, in which the highest aspirations for liberty and humanity are sinterwoven with historical associations expressed in language of the most classic purity. It was now however, after Schiller's muon with It was only, however, after Schiller's union with Goethe (1795) that, by their combined labours, Ger-man literature was brought to that classic perfection Goethe (1796) that, by their combined labours, German literature was brought to that classic perfection which, from a purely local, has since given to it a universal influence. Schiller, by his enthusiastic and sympathetic eloquence and tenderness, became the favourite of the people; while Goethe, with his many-sided intellect and boundless sensibilities, controlled by a strong will, became the acknowledged sovereign of German literature. The philosophic spirit of this age also gave birth in rapid succession to the master minds of Kant, Fichte, Hegel, and Schelling. Jean Paul Richter is a peculiar and powerful writer of this period, whose works, though characterized by obscurity and irregularity, are frequently lighted up by flashes of humour and brilliant gems of thought and feeling. Novalis (von Hardenberg) is another strangely-constituted writer, whose works, though few and fragmentary, contain scattered thoughts of such wisdom and genius as to give them a high place in the hiterature of his country. Ludwig Tieck, a more voluminous and connected writer than his friend Novalis, was also much more of a creative genius. His dramas, and and connected writer than his friend Novalis, was also much more of a creative genius. His dramas, and collection of ancient fairy and popular tales, often reflect the romance of medieval possay with much beauty and genius, but with a mystic feeling, bordering almost on superstition. To the so-called Romantic school belong the brothers Schlegal,—August Wilhelm, author of various critical and asthetical works, and a metrical translation of Shakespeare; and Friedrich, known as a writer on the history of ancient and modern literature, and the philosophy of history. The other writers translation of Shakespeare; and Friedrich, known as a writer on the history of ancient and modern literature, and the philosophy of history. The other writers of that and the subsequent period to the present time, are so numerous, that we can only afford to mention a very few of them. In almost every department of literature, the writers of the present or last century, in Germany, occupy a chief place. In philosophy, the names are numerous; but they are all eclipsed by the great names of Kant, Fichte, Schelling, and Hegel, and generally belong to one or other of these schools. (See German Philosophy.) In theology, Schleiermacher, Paulus, Bretachneider, Reinhard, Eichhorn, Hengstenberg, and a host of others, have done good service in the field of biblical inquiry. In philological and critical inquiries, occur the names of Wolf, Hermann, Boeckh, Othried Müller, W. von Humboldt, the brothers Grimm, Ffanz, Bopp, Bunsen, Benecke, Lachmann, Haupt. In history, Johannes von Müller, Heeren, Wachler, Friedrich von Raumer, Ranke, Lappenberg, Pertz, Niebuhr, Neander, Dahlmann, Gervinus, Menzel, Schlosser. In poetry, besides the names already mentioned, are Arndt, Körner, Heine, Uhland, Kinkel, Riokert, Schwab, Kerner, Mörike, Börne. In dramatic literature, are distinguished Kotzebue, Müllner,

Houwald, Grillparzer, Eaupach, Grabbe, Immermann, Gutskow, Mosen, Prutz, Laube, Helbel, and Frydag. In the field of historical or social romance, are Witziben, Van de Velde, Pichler, Häring, Spindler, Steffens, Koenig, Gutskow, Prutz, Mugge, Von Sternberg; ben, Van de Velde, Pichier, Häring, Bunnier, susuems, Koenig, Gutzkow, Pruts, Mugge, Von Sternberg; besides several ladies; as Ida von Hahn-Hahn; Paalsow. Among other literary writers of note, may be mentioned F. de la Motte Found, Achim von Arnim, Brentaus, Von Kleist, Amadeus Hoffmann, Chamisso, Kühne, Anerbach, and Stifter. The labours of A. von Humboldt in the field of natural science have given a powerful impulse to the German mind in that direction. Among their travellers are Martins in Brasil, Pöppig Humboldt in the field of natural soience have given a powerful impulse to the German mind in that direction. Among their travellers, are Martius in Brasil, Pöppig in South America, Tachudi in Peru, Schuehert in Greece, Lepsius and Brugsch in Egypt, Schomburgk in British Guiana, Biebold in Japan, Gützlaff in China, Barth and Vogel in Africa, the brothers Schlagentweit in Central Asia, and Leichhardt in Australia. On geography, ethnology, &c., are the works of Berghaus, Petermann, Stein, Hübner, Wappäus, Klöden, Kohl. In astronomy and mathematics, are Bessel, Hnoke, Struve, Gauss, Mädler; while in medicine and the natural sciences, are J. Müller, Ehreiberg, Burdach, Carus, Oken, Cotta, Schleiden, Von Buch, Liebig, Dove, Burmeister, Poggendorf, Erdmann, Gmelin, Gräfe, Vogt, Rokitansky, Wagner, and Doffenbach. In the history of language and literature, politics, and the social sciences, are Vilmar, Gervinus, Bouterwek, Becker, Wachler, Waagen, Savigny, &c.—Ref. Max Müller's Collection of the German Classics, Introduction; History of German Literature, by W. Metcalf, Koberstein's Grundeis der deutschen Nationalliteratur (1845-52); Gervinus' Geschichte der deutschen Nationalliteratur (1845-52); Gervinus' Geschichte der deutschen Nationalliteratur (1852) y Jul. Schmidt's Geschichte der deutschen Nationalliteratur (1852); Jul. Schmidt's Geschichte der deutschen Nationalliteratur (1852); Geschichte der deutschen Nationalliteratur (1852); Geschichte der deutschen Nationalliteratur (1852); Geschichte der deutschen Pienies philosophic spirit which characterizes Germany in the present day is only of comparatively modern origin. The old scholastic forms retained their place here long after they had been forsaken in France and England. The writings of Lord Bacch, of Descartes, and of Spinoza, which

been forsaken in France and England. The writings of Lord Bacon, of Descartes, and of Spinoza, which did so much for philosophy in their own countries, had but little influence in Germany. It was more particu-larly the writings of Locke which first excited any considerable degree of attention. His empiricism, considerable degree of attention. his empiricism, which sought to set up psychology as a regulator of metaphysics, aroused the opposition of Leibnitz, the first German that made an epoch in the history of the new philosophy, and who, from the influence which he exerted on all sides, must be regarded as the originator exerted on an sides, must be regarded as the originator of the philosophic spirit in Germany. Yet the fundamentals of his system,—monodology, pre-established harmony, the doctrine of innate ideas, wanted a strong systematic basis, being rather genial hypotheses than regularly-established propositions. This defect Ohr. Wolf set himself to remedy, and sought to establish a system of philosophy complete in all its nate. Wolf set himself to remedy, and sought to establish a system of philosophy complete in all its parts, according to the fules of strict logic; but, in so doing, he set aside the very doctrines which most particularly obsaracterize the system of Leibnitz. The wide circulation of his writings, the high esteem in which he was held by his contemporaries, the great number of his scholars and adherents, show the great influence which Wolf exerted for a time, He was destined, however, to outlive his reputation, for there soon came on a period of philosophical deadness in Germany. during period of philosophical deadness in Germany, during which a kind of eclecticism, devoid of principle, prewhich a kind of eclecticism, devoid of principle, prevailed,—the so-called "philosophy of common sene," borrowed from the English and French philosophers of the 18th century. Nevertheless, there also existed great mental activity of certain kinds. Poetry, the reform of education, politics, and religious enlightenment, deeply occupied men's minds; old eustoms in family and political life ware shaken, and a great and thorough movement was preparing itself in the quiet. With Immanuel Kant begins the more modera period of German philosophy; and although, at first, his with immanuel Kant begins the more modera period of German philosophy; and although, at first, his "Critique of Pure Reason" (Kritic der reinet Verwarft) was in danger of being everlooked; yet, after a time, this and the principal of his other critical works, which, after long preparation, made their appearance in rapid succession, gave a powerful stimulus to

scientific research. The cause of this lay, not only in the novelty and comprehensiveness of his investigations, but in that they exactly corresponded with the tenthe movelty and comprehensiveness of his investigations, but in that they exactly corresponded with the tendencies of the age-at the time. Excluding all dogmatism and fanaticism, maintaining the independence of apeculative inquiry, referring all theoretical apeculation to the accessible region of experience, the elevation of the mozal to the highest and ultimate of all human endeavour; these in general constitute the main features of his philosophy, which he wisked to be cultivated rather with a view to its social than to its mere philosophic importance. He also entertained the hope that, by means of critical investigations into the nature of the human mind, it might be possible to reconcile the opposing systems of empiricism and rationalism, of sensualism and spiritualism, &c., and to discover a series of comprehensive principles to which the convoversies of the philosophic schools might be referred in the last instance. That this hope was disappointed was owing to this, that Kant sought to support the old metaphysic of the schools by a psychology which itself rested on the basis of that metaphysic. Besides, there was wanting in the heyday of Kantism any sufficient point of unity for the several parts of philosophy. Of this want K. L. Reinhold was the first to become conscious; and scepticism, as in Schulze's Anexidenus, and degree that the contract and others. scious; and scepticism, as in Schulze's Anesidemus, and dogmatism, in the writings of Eberhard and others, dogmatism, in the writings of Eberhard and others, raised their feeble opposition to the now triumphant criticism. J. G. Fichte believed that he had found that absolute point of unity which the criticism of Kant had indicated, in the fact of consciousness. Fichter verweling on the path which Kant had pointed out, changed the half-idealism of Kant into a complete idealism, while he declared the Ego to be, not only the bearer and source of knowledge, but also the only reality, the representation and act of which is the world. In the Ego, knowing and being were identical; it was at once the principle of existence, and knowledge and nature appeared only as the reflex of its absolute activity. With this idealism began akind of revolutionary excitement among the philosophic minds of Germany, which contrasted strongly with the quiet and sober spirit of Kant. System followed system, philosophic literature became overwhelming, and the public excitement was general for twenty or thirty years. The ment was general for twenty or thirty years. The meteors which made their appearance in the philosophic heavens of Germany, for the most part disappeared as suddenly as they had blazed forth. Schelling was the first to exert a more general influence, and changed the idealism of Fiohte, under the influence of Spinoza (who had been again brought into notice by Jacobi), into the so-called philosophy of identity. This system set out originally with the assertion that, as Fiohte has deduced nature from the Ego, so, by reversing the process, the Ego may be deduced from nature; that both forms of philosophy find their basis in the absolute, as the identity of all opposites,—the ideal and real, subject and object, spirit and matter. In order to carry out this assertion, Schelling assigned intellectual intuition as alone corresponding to the absolute; yea as representing, and identical with, the absolute itself. The organ of this intuition was called reason, and, as such, was opposed to the reflection of the understanding, which was held to be quite incapable of comprehending absolute identity. The relation of the actual phenomenal world to the absolute was held to consist in this, that the latter represents itself in a the first to exert a more general influence, and changed comprehending absolute inemuty. The remain of one about phenomenal world to the absolute was held to consist in this, that the latter represents itself in a multiplicity of appearances, steps out of "indifference" into difference, manifeste itself in the latter, &c. He sought to demonstrate this identity in non-identity, and non-identity in identity,—especially with regard to natural philosophy in special cases, in which the highest merit to which he and his followers are entitled is the having opposed the empiricism of mere observation and computation in natural investigations, and to have contributed to the swakened interest in and to have contributed to the awakened interest in the natural sciences. For in contemuing experience and reflection, occasion was also afforded to a fanciful

the direction indicated by Fichts and Schelling, the philosophy of Hegel also asserted itself, and attempted to develop in regular succession the equature of the intellectual intuition by the dialectic method. He indeed threw off the lawless play of fanciful combinations; but he sought for the expression of speculative thought, not in those laws of the comection of thought thought, not in those laws of the consection of thought which have been recognized for thousands of years, but in a dislectic, the essence of which consists in the analysis of all the established principles of thought, and whose process consists therein that every conception generates out of itself its opposite, and uniting this with itself, inwardly enriches itself, and in this way proceeds to still higher stages. This method pretended to be identical with the thing itself; Hegel, with analysing preservations cought to carry out. tended to us defined with the thing testing a security with lenduring perseverance, sought to carry out through the whole field of philosophic inquiry, and divided his system into the three provinces of legic, the philosophy of nature, and the philosophy of mind. While the systems above-mentioned form a tolerably statishing the company of the philosophy of the philosoph While the systems above-mentioned form a tolerably straight line of progress, there excess certain other systems, as that of J. F. Herbart, in opposition to the idealism of Fichte, and which took a direction quite contrary to the philosophy of the time. Herbart, Schelling, and Hegel are the only thinkers that can claim to have exerted any general influence since the time of Kant. Among the numerous other thinkers of this time, who were chiefly occupied in defending or remodelling the older systems, we may mention Krug, Fries, and others, who were employed in the development of the Kantian system; Steffens, Oken, Schubert, F. von Baader, and Eschenmayer, who were employed chiefly in physical researches; those who Schubert, F. von Baader, and Eschemayer, who were employed chiefly in physical researches; those who attempted to exhibit systematically the philosophy of Jacobi; the different attempts to bring back philosophy to an empirical psychology; the peculiar specularive attempts of Schleiermacher, J. J. Wagner, Krause, Weisze, the younger Fichte, Branisz, E. Beinhold, A. Trendelenburg, H. Ritter, A. Günther, and others; the different tendencies within the Hegelian school; and, finally, the relation which Schelling latterly took up to his own earlier teaching, as well as to that which up to his own earlier teaching, as well as to that which had been developed out of them. In the same propor-tion in which during the last fifty years the science of philosophy has been prosecuted in Germany, has also its history been studied; and indeed the Germans were the first who sought to comprehend and represent the history of philosophy as a whole, and to throw light upon the more important parts of it by valuable special extensions. the the street important parts of it by valuable special wheaties. The rapid change in the philosophic systems, and the extravagances which characterized some of them, have often been much blamed and made sport of, and it seems, as a consequence of that, that there has been for some time a bull in the interest taken in nas been for some time a full in the interest taken in speculation, and a sort of sceptical aversion to all proper philosophic inquiry has taken the place of the former enthusiasm. Yet the influence of philosophy in elevating and strengthening the scientific spirit in Germany has been great and beneficial; and there is almost no region of inquiry in which a deeper and

almost no region of inquiry in which a deeper and more thorough mode of treatment is manifest as the fruits of this philosophic spirit.—Ref. Brockhaus, Conversations Lexicon.

Greman Silven is a useful alloy, composed of 51 per cent. of copper, 30.6 of zinc, and 18.4 of nickel. It is, in fact, brass, to which nickel has been added to give it a white tinge. It is manufactured in large quantities at Birmingham, and is much used for forks, spoons, and other table requisites, in consequence of its durability, incorrodibility, and resemblance to silver. It is also much used for electro-plating.

Greman Trachogy —The important negation which

GERMAN THEOLOGY.—The important position which the Germans in the present day occupy in the field of theological speculation entitles them to some special notice in a work of this kind. The phrase German theology is commonly restricted to the doctrines of Protestant Germany, as the theology of the Catholic church there does not differ materially from Roman Catholic manuscript. and reflection, occasion was also afforded to a fanciful church there does not differ materially from mone and of speculation, which frequently had nothing Catholicism generally. It is, however, principally, farther in common with science than the name, and on this account many dark opinions in the regions of poetry, religion, and social life came to unite themselves with the philosophy of Schelling, and which often led to the most strange aberrations into romanicism, mysticism, and a tendency to Catholicism. In Christianity. The father of German rationalism is

# German Theology

generally regarded to have been Wolf (1679—1754), who introduced into theology his distinction between natural generally regarded to have been Wolf (1879—1764), who introduced into theology his distinction between natural and revealed religion, and a number of rationalistic ideas. His system was adopted by numerous theologicans, both of the Lutheran and Reformed churches, and thus at once deeply penetrated into theological literature and the schools. J. A. Ernesti, a contemporary of Wolf, established the historico-critical school of Protestant excepsis, by applying the rules of classical philology to the interpretation of the Bible. Semler (1725-91) distinguished theology from religion (i. e. morality); claimed the right to subject the whole canon of Scripture to the freest investigation, and aid down as a supreme principle, that the Scriptures are to be regarded as canonical and of divine origin, only in so far as their contents are of an ethical or moral nature. He also distinguished between a local, temporal, and therefore transitory part of the Bible, and the imperishable word of God. W. A. Teller (1734—1804) published, on the basis of the biblical studies of Ernesti, Semler, and their followers Michaelis and Bichhorn, a new system of Christian doctrine, studies of Ernesti, Semler, and their ionowers mione-elis and Eichhorn, a new system of Christian doctrine, and prodaimed a practical religion of reason, as the essence of Christianity. A new theory of far-reaching influence was set forth by Töllner (died 1774), who distinguished between Holy Writ and the word of God, the latter of which he found also in all other religions, and in reason. He distinguished different degrees of inspiration, and maintained that the same degree did mapiranon, and maintained that he same degree due not exist in all perts of the Holy Scriptures. Against the assumptions of this new school, orthodox theology was principally defended by Bengel, Crusius, Oettinger, Zollikofer, and Spalding. English deism was transplanted into Germany by Reimarus (1694—1768), in the calebrated "Wolfenbuttel Fragmenta," first published by Lessing. He denied the possibility of a revelation, and declared, as the principal doctrines of natural religion, the existence of God, a divine providence, and the immortality of the soul. Moses Mendelssohn, a Jew (1729–96), adopted the same views, and declared the happiness of man to be the principal aim of religion. Other writers of the same school were Steinbart (1738–1809): Basedow (1723–90); and Babrdt (1741–92). An not exist in all parts of the Holy Scriptures. Against Other writers of the same sensol were Steinbart (1738–1809); Basedow (1723-90); and Bahrdt (1741-92). An important organ of this school was the "Allgemeine deutsche Bibliothek," published (1765-92) by Nicolai. Lessing (1729-81) also partially belonged to this school, and maintained that Christianity is essentially a system of education for mankind, in which the Scriptures are of education for mankind, in which the Scriptures are text-books, which may perhaps be superseded when humanity is educated for the reception of the new everlasting gospel. He also held that revelation gives to man nothing more than reason alone would have sufficiently developed in time. The path marked out by Lessing was further pursued by Kant, who declared the ideas of God, liberty, and immortality, indemonstrable by pure reason, and that the only thing certain in itself is the moral law, which conducts us to a practical faith in God and immortality. Through him, the terms rationalist (one who dealers natural religion alone to be morally necessary, though he may admit revelation), naturalist (one who denies the reality of a supranatural divine revelation), and supranaturalist (one who considers the belief in revelation a necessary element in religion) came into use, and rationalism (one who considers the belief in revelation a necessary alement in religion) came into use, and rationalism and supranaturalism became the principal division of the theological schools. The first rationalistic system of dogmatic theology was published by Henke, the most complete and celebrated by Wegachaider; besides whom, among the most distinguished were Paulus of Heidelberg, and Röhr of Weimar. The foremost representatives of the supranatural theology were Storr, Knapp, Hahn, and Steudel. A middle course between these two was first attempted to be established by Raunhard, and the most prominent of his successors in neese two was urat attempted to be established by Benhard, and the most prominent of his successors in this work were Schott and Bretschneider. Instead of attempting to pursue a middle course, Sohleiermacher sought to merge the two into one entirely new system, acknowledging the claims of both. He found the proper source of all Christian life and knowledge in the proper source of Christian consciousness. proper source or an Christian are and knowledge in the pious sentiment or Christian consoiousness, in which the subject comprehends itself, both in the totality of its being and in its being determined by the Christian principle reigning in the race. In this consciousness, it becomes assured of the reality of a new divine prin-ciple of life, which reveals itself in Christianity. Heve-

## Germination

istion is not, according to him, an external law, claiming submission from the subjective reason, and nothing more is demanded of the latter than to recognize itself as being determined by the Christian principle, and more and more to penetrate itself with it. The views of Schleiermacher not only met with many supports of Schleiermacher not only met with many supporters, but likewise execused an important influence upon the schools which were opposed to it. Most of the ad-herents of Schleiermacher defended from his standberents of Schleiermacher defended from his stand-point all the esantial doctrines of biblioal orthodoxy; as Neander, Ulman, Lücke, Umbreit, Olahausen, Hundes-hagen, &c. Others attempted a middle ourse between it and German Protestantism; as Twesten, Nitsach, and J. Müller. A third school, claiming fuller indepen-dence of theological investigation, is represented by A. Schweizer and Hammgarten-Crusius. The most recent influence of lasting inventances in the development of influence of lasting importance in the development of influence of lasting importance in the development of the German theology came from the philosophy of the absolute, introduced by Schelling, and completed as a system by Hegel. According to this view, the popular religious which have existed in the world have been the several points by which the divine self-consciousness has developed itself. After the death of Hegel, his school became divided into those who used an orthodox and those who used a heterodox mode of avancasion, the one attempting to develop orthodox his school became divided into those who used an orthodox and those who used a heterodox mode of expression; the one stempting to develop orthodox views of Christianity out of his system, the other maintaining that pantheistic ideas were the true results of it. Among the former were Daub, Marbeincke, Rosenkranz, Göschel, Erdmann, and Conradi; among the latter, Strauss, author of the "Life of Jesus," and L. Feuerbach, author of the "Essence of Christianity. The so-called Tübingen school originated with F. C. Baur, who introduced the philosophy of religion, as a Christian science, into the history of Christian doctrines, and sought to comprehend the historic development of the dogma as the dislect process of the idea itself. Rejecting the authenticity of most of the books of the New Testament, and ascriving to them a later origin, he endesvoured, by numerous writings, to fill up the vacuum thus left in the history of Christi and earlier Christianity. Among his followers, Schwegler and Zeller were the most distinguished. Their writings called forth an immense number of opponents; among whom were Thiersch, Dorner, Schaff, Bleech, Hase, and Ewald. Attempts have recently been made by T. H. Fichte, O. P. Fischer, Weisse, Wirth, and sothers, to establish a system of speculative theism, in opposition to rationalistic and speculative theism, in opposition to rationalistic a cal Church Gazette, of Hengstenberg, became an influential organ of this party. It was, however, almost wholly a Lutheran orthodoxy which was thus almost wholly a Lutheran orthodoxy which was thus restored. Its principal theologians are Hengstenberg, Hävernick, Keil, Klieforth, Kahnis, Rudelbash, Guericke, Delitzsch, and a host of others. This revived Lutheranism soon split into an old and a new school, and some of the latter were charged with having introduced into the system the most dangerous innovations. Notwithstanding the great diversities that have prevailed, and still prevail in Germany, the leading tendency is towards orthodoxy, and rationalism is on the wane. In every single department of German theology an exceedingly voluminous and thorough literature has been produced, and some branches of literature has been produced, and some branches of theology have been cultivated almost exclusively in

theology have been cultivated almost exclusively in Germany.—Ref. New American Cyclopadia.
Generators, jermin-oi-shaw (Lat. germino, I sprout), in Bot., the beginning of vegetation, or the development of the embryo (which see) into an independent plant, capable of supporting itself. The time required for germination varies much, according to the nature of the seeds and the conditions under which they are planed. Generally experience accommendations. nature of the seeds and the conditions under which they are placed. Generally speaking, seeds germinate most rapidly directly after they are gathered. If preserved till they are quite dry, in some cases the process of germination requires months or even years. The seeds of the garden oreses will frequently germinate in twenty-four hours; but the majority of seeds do not germinate for from six to twenty days. Heat is the agent which most accelerates germination. A certain amount of moisture, and a free communication

935

# Gerund

with the atmospheric sir, are in all cases necessary to the process. Absence from light is a favourable con-dition. Seeds sprout most readily during spring or summer, in loose pulverised and properly-drained soil, at a moderate depth; as, under such circumstances, air, moisture, and warmth have free access, while light at a moderate depth; as, under such circumstances, ari, moisture, and warmth have free access, while light is excluded. Certain chemical changes, the most important being the conversion of starch into sugar, take place in the seed, and the embryo is nourished by the products of these changes. Thus nourished, it increases gradually in size, and ultimately bursts through the integuments of the seed. Its lower extremity, or radiole, is commonly protruded first, and, taking a downward direction, becomes fixed in the soil. The opposite extremity soon elongates upwards, and is terminated above by the plumule or gemmule, which is the first terminal bud, or growing apex of the stem; and at the same time the cotyledonary portion is either left under ground, or is carried upwards to the surface. During the gradual development, the embryo continues to be nourished from the matters contained in the albumen or cotyledonary portion, and is ultimately enabled to produce its first leaves and root. The young plant is then in a position to acquire the necessary nourishment by itself, for its further support and growth, from the media by which it is support and growth, from the media by which it is surrounded; and being rendered independent of the seed, has no need of the cotyledonary portion, which accordingly perishes. The spores of acctyledonous accordingly perishes. The spores of acctyledonous plants develop roots indifferently from any part of their surface: this mode of germination is termed beterowheat. In the germination of monocotyledonous embryos, the radicle is not itself continued downwards so as to form the root, but it gives off branches of nearly equal size, which separately pierce its extremity and become the rootlets. Each of these rootlets, at the point where it pierces the radicular extremity, is surrounded by a cellular sheath, termed the coleorhiza. This mode of germination is commonly termed chall. surrounded by a centuar sneath, termed the evectors are.

This mode of germination is commonly termed endorhizad. The radiole of a dicotyledonous embryo is
itself prolonged downwards by cell-multiplication just
within its aper, to form the root; and this mode of
germination is distinguished as exorhizad. (See Boor,
STRE.)

within its distinguished as exerciscal. (See Root, Stram.)

GREUND, jer'und (Lat. gerundiums from gero, I carry), in Lat. Gram., is a part of the verb used to denote something as being done; thus, legendum, reading, from lego, I read. It is a sort of verbal substantive, being declined like a noun, but having the same power of government as its verb. In English the present participle occupies the place of the gerund.

GRENHAGES, gene-ne-roll-see (after Gesner, the naturalist), in Bot., the Gesnera fam., a nat. ord. of Diocyledones, sub-class Corollifora. Herbs or soft-wooded shrubs. Leaves wrinkled, exstpulate, generally opposite, or whorled; flowers irregular, showy; calyx half-superior, 5-parted; corolls 6-lobed; stames diandrous or didynamous, with the rudiment of a fifth. Ovary half-superior, 1-celled, surrounded by an annular fleshy dise, or by glands; style 1. Fruit espeular or succulent, 1-celled, with 2-lobed parietal placentes. Seeds numerous, with or without albumen; embryo with minute cotyledons and a long radicle. The plants of this order are chiefly natives of warm or tropical regions. On account of the beauty of their flowers, they are much cultivated in this country. There are 69 genera and about 275 species.

GREYA ROMANORUM, jest-til ro-ma-no'-rum (Lat., the deeds of the Romans), is the tile of a legendary work of the middle ages, written in Latin, and whose tales are chiefly taken from the history of the Roman emperors, or belong to that period, and are accompanied with moralising expositions; whence it is also called Effective Moralisate. The 'stories are short, and display an almost childish simplicity. They were spointed to be read by the monks, and were generally much read down to the 16th century. They were translated into several languages, and formed a risk mine for the earlier fabulists and novelists. Grässe, in his German translation of this work (2 vols. Leipnic, 1842), assigns its suthorship, apparently with reason, to a certain monk named Elimandus, who

#### Giant

Giant

carry), in Physiol., is applied to the period which interenes between the time of conception and that of delivery. This period differs greatly in different animals. In the human species it is nine calendar months, or, more strictly, forty weeks, or 280 days; but by certain circumstances the period may be prolonged or shortened by several weeks; and sometimes the birth takes place as early as the seventh month. In the cow the period of gestation is nine months, in the mare eleven, in the dromedary twelve, and in the elephant twenty-one. In the smaller animals it is much less; being in the dog about sixty-three days, in the cat fifty-six, the rat twenty-eight, in the sow four months, and in the sheep and goat about five.

GRUM, js-um (Lat.), in Bot., agen. of the nat. ord. Rosaces. The most interesting species is G. urbasum, the wood svens, a common herb in our hedges and thickets. The roots have an aromatic flavour, something like that of cloves. They were formerly much used for flavouring ale, and to some extent in medicine, for their tonic and astringent properties.

GHER, ghe, a sort of butter used by the natives of India, which undergoes a peculiar process in order that it may last for some time. The milk is first boiled in large earthen pots for an hour or two, after which it is allowed to cool, and a little dhye, or curded milk, is added, in order to make the whole more readily coagulate: after the lapse of some hours, the mass is converted into curds, and is ready for churning. The contents of each jar, to the depth of some five or six inches, are then removed or skimmed off, and placed in a larger earthenware utensil, in which they are

The contents of each jar, to the depth of some five or six inches, are then removed or skimmed off, and placed in a larger eartheaware utensil, in which they are churned by means of a small piece of split bamboo for about half an hour; then some hot water is poured into the jar, and the churning continued for half an hour longer; after which time the butter is found to be formed. When this becomes rancid, as it necessarily does in a day or two, it is again melted in an earthen vessel, and boiled until all the water has evaporated from it; after which a little salt or betel-leaf is put into it, and it is covered up in closed pots to be kept for use. Ghee forms a very important article of internal traffic through India, as the natives consume great traffic through India, as the natives consume great quantities of it, although it is not much esteemed by Europeans.

quantities of it, although it is not much esteemed by Europeans.

GRIEELLINES, gib'-hel-lines, in the history of the Middle Ages, was the name of a political party in Germany and Italy, which, with their opponents, the Greiphs, distracted the peace of these countries, particularly the latter, for several centuries. The Ghibellines were the supporters of the authority of the German emperors over Italy, to which the Guelphs were opposed. (See Guelpes and Ghierlines.)

GROSTS. (See APPARITION.)

GLINT, ji'-ānt (Fr. géant, from gigas, the Latinized form of a Greek word, probably formed from ginesthat and ge, signifying 'the earth-born'), an individual of extraordinary stature and bulk. The existence of a race of giants, or of individual instances far exceeding those enhibited in modern times, was fully believed in, up to the commencement of the present century. This belief was founded partly upon scriptural evidence, partly upon the discovery of enormous bones supposed to be those of human beings, and partly upon the accounts handed down by ancient and mediaval writers. In the Old Testament, the name of giant is applied to several races of men; but the appellation seems to refer more to violence and physical power than to stature. The Anakims and some other tribes seem, however, to have been distinguished from other races by their surerior attempts and uncontious. seem, however, to have been distinguished from other races by their superior strength and proportions.
There are several instances in the Scriptures of individual giants; such as Og and Golisth. The height of
the former is not mentioned, but the latter, at most, were appointed to be read by the monks, and were generally much read down to the 16th century. They generally much read down to the 16th century. They were translated into several languages, and formed a trick mine for the earlier fabulists and novelists. Grasses, in his German translation of this work (2 vols. Leipzio, 1842), assigns its authorship, apparently of supposed giant were exposed by the action of with reason, to a certain mouk named Elimandus, who died 1227. The newest edition of the original text is that edited by Keller (Stuttgart, 1842).

Grassaxiow, jes-tai-shun (Lat. geste:io, from gero, I posed giant were found on the Rhone: it was stated

Gilding

that the skeleton had been found in a tomb 30 feet long, bearing the inscription "Teutobochus Rex." The Parisiane growded to see the bones of the King Teutobochus; but it was afterwards found that the The Parisina growded to see the bones of the King Teutobochus; but it was afterwards found that the remains were not those of a man, but of a mastodon. In this country, Dr. Mather, in 1712, announced the discovery of the bones and teeth of a giant in the state of New York. The statement was published in the Philosophical Transactions; but it was subsequently ascertained that the bones in this case also were those of a mastodon. Among classical writers, instances are numerous of giants, but not worthy of belief. Plutarch states that, when the grave of Anteus was opened by Serbonius, the body was found to be full 60 cubits long. Pliny also relates that, at an earthquake in Orete, the bones of a giant 46 cubits in length were disclosed. Coming to more reliable evidence, it seems certain that a height of even more than nine feet has been attained. In the museum of Trinity College, Dublin, there is a skeleton 8 feet 6 inches in height; in the museum of the College of Surgeons of England, is snother 8 feet. Great diversity, as to height and airs, prevails smong the human race. In northern latitudes, men are below the ordinary standard, many being less than four feet. In temperate climates, the height varies from 4½ feet to 6 feet; but this is sometimes exceeded, as mentioned above. As a general rule, giants are of rarer occurrence than dwarfs; they are usually of a lymphatic temperament, of a delicate complexion. Often deformed, and generally badly proare usually of a lymphatic temperament, of a delicate complexion, often deformed, and generally badly pro-portioned. Their muscles also are flabby, and their voices weak. They are seldom long-lived, and in this voices weak. They are seldom long-lived, and in this respect are the reverse of dwarfs. O'Byrne, whose skeleton is in the Royal College of Surgeons of England, died at 22, while Borowlaski, the dwarf, died at 98. (See Dwar.) It has also been observed that giants show a want of activity and energy both in body and mind, while dwarfs are usually lively, active, and irascible. The causes which occasion the production of giants are not much understood. According to Geoffroy Saint-Hilaire, Bishop Berkeley attempted to manufacture a giant. He reared an orphan boy, named memufacture a giant. He reared an orphan boy, named Magrath, on certain hygienic principles, and succeeded so far that at the age of 17 he was 7 feet in height. He died, with all the symptoms of old age, when he had completed his 20th year, at which time he was 7 feet 8 inches high. It is a singular fact, that in the mythology of all the Indo-Germanic nations, giants hold a marked position. A mongst the Greeks, they were represented as hideous beings of monstrous size, having the tails of dragons, and living in volcanic districts, to which they had been banished after their war against heaven. The gods, with the assistance of Hercules, were supposed to have imprisoned them under Etna and other volcances. They were fabled to have sprung from the blood which fell upon their mother Gs (the earth) from the alain Ouranus (heaven). This mingling of heavenly with earthly descent, together with the places of their abode, evidently points to the mysterious volcanic convulsions of nature, which they were intended to typify. In the dently points to the mysterious volcanic convusions on nature, which they were intended to typify. In the mythology of northern nations, giants play a still more important part. They believed that the first created being was Ymir, "the Ancient Chaos," and the pro-genitor of the frost giants. The origin of Ymir was long before the creation of heaven and earth. In the long before the oresided of heaven and east. In the beginning, a world existed in the far north, in which was a well, from whence flowed a poisonous stream hardening into ice. As this accumulated, it formed the northern part of Ginnungagap, or the abyse of abysess, the southern extremity of which was radiant with heat and light from another world. The meeting of with heat and light from another world. The meeting of heat and cold produced drops which, by the agency of the All-Father, or orestive power, which had sent them forth, became a living being, and received a human form. Ymir, the giant, thus created, was nourished by four streams of milk, and, while he slept, a man and woman grew from under his left arm, while a son was produced from his feet. Other beings were afterwards formed from the salt and snow-covered stones, and from these the three brothers Odin, Vili, and Ve, were born. These three were gods, and having slain Ymir, they dragged him into the middle of Ginnungagap, formed the ocean and all waters from his blood,

0.94

and from his huge body heaven and earth, and all solid bodies. All the frost giants, except Bergelmir, perished with Ymir. He begame the father of the new giant race of the Jötuns. It is a common belief in many nations that mountains and islands have been raised. namenty nations that mountains and islands have been raised, and rocks and mountains strown down, by giants. Giants are also used to typify the heathen element in its conflict with Christianity. Graous, djoor (Turk., a dog), is a term applied by the Turks to Christians, or, indeed, to all who are

ot Mohammedans.

not Mohammedans.

GIBROSITY, gib-bos'-c-te (Lat. gibbositas, from gibbus, a swelling or protuberance), in Med., is applied to a hump or other irregularity or swelling on the back, or any other part of the body.

GIBROSIS, gib'-bus (Lat. gibbus, hunched, humped), an expression applied to the convex or protuberant shape that the moon presents in its second and third quarter, before attaining the perfect circular form that it exhibits when it is full.

GINDERSES gid-denses (Sax gidio Lat. perfect.)

that it exhibits when it is full.

GIDDINESS, gid'-de-nes (Sax. gidig, Lat. vertigo, from verto, I turn), in Med., is a dizziness or swimming of the head, with more or less of mental confusion, and a loss of power to balance the body. The objects around him in many cases appear to be moving about in different directions, often conjoined with a sense of dimness or darkness, or with sounds of bells or drums in the ear. It generally comes on suddenly, and is symptomatic of various diseases, arising, as it does, from some disturbance or debility of the nervous power. It generally precedes a fainting fit, or an attack of spoplexy; attends fevers, inflamnations, and many other diseases, and not unfrequently arises from some organic disease, and not unfrequently arises from some organic disease of the brain or heart. Most frequently, however, it arises from indigestion, and may be got rid of by means of some aperient medicine. When this falls, or when it is of frequent occurrence, medical advice ought to be sought. ought to be sought.

ought to be sought.

Giff, giff (Sax. giff, Lat. donum, donatio), in Law, is the transferring of the right and possession of a thing by one man to another, voluntarily and gratuitously. In this latter respect, gifts are distinguished from grants, which are always made upon some consideration or equivalent. The giver of the thing is called the donor, the receiver the dones. Gifts are divided, as regards their subject-matter, into gifts of chattels real and gifts of chattels personal. Under the former head may be included all leases of land for years, assignments, and surrender of these leases, and years, assignments, and surrender of these leases, and all other methods of conveying an estate less than free-hold. A gift of chattels personal is the act of transhold. A gift of chattels personal is the act of trans-ferring the right and possession of them, and may be done either by writing or by word of mouth, attested by sufficient evidence, of which the delivery of posses-sion is the strongest and most essential. The law generally looks with some degree of suspicion upon gifts, and they are usually considered to be fraudient if creditors or others become sufferers thereby. Where a gift has been executed by delivery of possession, it is not in the donor's power to retract it; but so long as the gift has not been completed by delivery of possession, it is not properly a gift, but a contract, and this a man cannot be compelled to perform but upon good and sufficient consideration. The deed or conveyance and sumcient consideration. The deed or conveyance creating an estate tail is also called a gift, from the operative words of the convoyance, which are always "I give," or "have given." It differs in nothing from a feoffment, but in the nature of the estate passing by it; and gifts in tail are equally imperfect without livery of seisin, as feoffments in fee-simple. (See ENTAIL.)

GILBRETHES, gil'-ber-tins, in Eccl. Hist., the name of a religious order, founded by St. Gilbert, in Sem-pringham, in Lincolnshire, about the year 1148. The monks of the order observed the rule of St. Augustine, and were accounted canons, and the nuns followed that of St. Benedict. There were about twenty-five houses of this order in England and Wales at the time of the

of this order in England and wases we dissolution of the monasteries.

Gilding, gild-ing (Sax, gildan, to gild), the art of covering bodies with a thin coating of gold, either by chemical or mechanical means. In chemical giding, the gold is applied to metallic surfaces by the agency of chemical affinity. One of the best metals for gilding on is a mixture of copper with one-seventh of brass.

2 r 3

Copper itself is too soft and dark-coloured; ordinary brass, however, serves the purpose quite well. The gold employed is calleds' fine gold,' and is 'free from alloy. In orderto apply the gold to the metal required to be gilt, it is first combined with mercury, a quantity of the former being boiled with five or six times its weight of the latter. When the gold is dissolved, and the amalgam sufficiently boiled, the fluid mass is noured out into cold water, and then becomes semi-fluid. It is next put into a piece of chamois-leather and squeezed; by which means the particles of quick-silver escape through the pores of the leather, whilst the gold is retained. The amalgam, if good, is then of about the consistency of stiff olsy, and has a greasy and gritty feel when divided with a bone spatula. In order to apply the amalgam to the surface of the copper, or other metal, it is necessary to use a solution of nitrate of mercury, as otherwise there is no chemical affinity between the substances required to be brought in contact. This solution is called, in commerce, "gilder's aqua fortis," and when a piece of metal is immersed in it, its surface is immediately converted into an amalgam to which the mercury and gold amalgam closely adhere. The methods in which this operation is performed in detail depend open the size and nature of the articles to be gilded. After receiving the gold covering, the gilded articles are washed and dried in a careful manner. Gilt articles of all the better qualities are submitted to an after-process, for the purpose of giving them a deeper orange tint, by first Copper itself is too soft and dark-coloured; ordinary in a careful manner. Gilt articles of all the better qualities are submitted to an after-process, for the purpose of giving them a deeper orange tint, by first covering them with a chemical compound, and then placing them on a heated iron plate, when the warm gold surfaces become oxidized. Most gilt articles are gold surfaces become exidized. Most gilt articles are also burnished by a stone burnisher, formed of a polished piece of black hæmatite. In the mechanical mode of gilding, gold-leaf or gold powder is applied and fixed to various substances by different means. Thus gold may be applied to wood, plaster, pasteboard, leather; and also to metals, such as silver, copper, iron, tin, and bronze; so that gilding includes several arts exercised by men employed in very different trades. Wood-work is gilt by brushing over the surface desired to be operated upon with a solution of parchment size mixed with a little whiting. After filling up the holes and irregularities, the surface is again brushed over with a composition of the same sort. shed over with a composition of the same sort. After this operation has been repeated several times, the plain parts are moistened and smoothed down with the plant parts are moistened and smoothed down with pumice-stone, &c., and when dry the work is covered with several coatings of gold size, a peculiar substance,, of which deer's fat is said to form the principal ingre-dient. The gold-leaf is then carefully laid on with a sort of fine comb, called a "tip," and pressed into the cavities with a dry camel's hair pencil. When dry, the gold is burnished with a stone in some parts. This constitutes hurnished with a stone in some parts. This constitutes burnish-gilding: oil-gilding is performed with a gold size of an oily nature; and japan-gilding, effected with japan size, is intended for those surfaces which are to be exposed to the weather. For a description of the process for gilding by means of electricity, see ELECTRO-PLATING AND GILDING.
GILL, jill (from Low Lat. gilla, a drinking-glass), is a measure of capacity holding the thirty-second portion of a gallon, or the fourth portion of a pint.
GILDENIA, gill-lo'-ne-d, in Bot., a gen. of the nat. ord. Rosuces. G. trifoliata and stipulaces are pretty North-American plants, with lobed, discoloured leaves and white flowers. The roots of both species are used medicinally, and are commonly known under the names constitutes burnish-gilding : oil-gilding is performed

medicinally, and are commonly known under the names

medicinally, and are commonly known under the names of Indian physic and American ipecacuanha. In small doses they are tonic; in larger doses, emetic.

GILLIESIACEM, gille-se-al-se-e (after Dr. Gillies, of Conception, in Chill; in Bot., the Gilliesia fam., a nat. ord. of Monocotyledones, sub-class Petaloidem, consisting of small herbaceous bulbous plants, with grass-like leaves and spathaceous flowers. There are but two leaves and southacous flowers. There are but two geners, -Gilliesia and Miersia, containing five species, all natives of Chili. Their properties and uses are

United are known by different names in commerce; Gills, gills (Swedish gel), a term applied to the apparatus possessed by all fishes, by means of which their respiration is effected exclusively through the Ginsung. (See Param.) Ginsung. (See Param.) on each side of the neck, and are composed of several amine fixed on arches. These lamine are covered Hist. Cameloparadis Girafia, is one of the tallest 938

with a vast number of minute blood-vessels, and are with a vast number of minute blood-vessels, and are so formed as to present a considerable surface to the water, so that a sufficient portion of oxygen may be received by the blood. As the oxygen is continually being removed, the water becomes deteriorated, and it is consequently necessary that a constant current should flow over them. This is effected in most fishes by their taking the water in at the mouth and expelling by their taking the water in at the mouth and expelling it under the gill-covers in regular respirations. The blood, which is continually being sent to the gills from the heart, is distributed, by means of the arteries, to every part of the body; from whence, by means of the veins, it comes back again to the heart.

Gimmlas, gim'-bills (Ang.-Nor.), the two hoops of brass in which the mariner's compass is suspended, in order to secure a briscontal nosition for the compass.

order to secure a horizontal position for the compass, card, and needle, under any circumstances. This is effected by means of their being fitted one within the other. The compans is suspended within the inner hoop other. The compase is suspended within the inner hoop is by two pivots at opposite points, and the inner hoop is suspended in a similar manner within the outer hoop, by pivots that are in a line at right angles to that which passes through the pivots, by which the compass-box is suspended in the inner hoop. A compass supported in this manner is said to be suspended on

gimbals.

Gir, or Girs, fin (contraction of engine), a machine employed for raising heavy weights, driving piles, &c. It consists of three poles, about twelve or sixteen feet long, placed in the ground eight og nine inches apart, united at the top by a rope twisted several times round each, or by an iron ring. Two of the poles are kept their proper distance apart at the bottom by a movable iron bar placed between them in a horizontal position; windless is also several by the contraction of a windlass is also secured between the same two poles about 34 feet from the ground. When in use, the gin about 34 feet from the ground. When in use, the gin is set up over the object to be lifted, and a rope, one end of which is secured round the windless before mentioned, and carried thence through a pulley at the

mentioned, and carried thence through a pulley at the top of the poles, is then fixed to it, when, by turning the windlass, by means of handspikes, it may be raised the required height.

Gin (from Fr. genièvre, juniper), an ardent spirit, largely manufactured in London and other places, and originally flavoured with juniper berries, from which it derives its name. Geneva is frequently confounded with gin; the former is, however, merely procured by the fermentation of the berries of the Juniper communication of the berries of the Juniper communication of the price of the Juniper communication of the Junipe with gin; the former is, however, merely procured by the fermentation of the berries of the Juniper communis. Hollands gin is a variety of corn spirit, which was formerly wholly imported from Holland. The popularity of this spirit induced the English distillers to produce a similar liquid; but a difference can easily be detected by good judges. At the present day, English gin consists of plain corn spirit, lavoured with oil of turpentine and a smell quantity of other substances. It is consisted that Hollands gin may contain a proportion of juniper, but as a general rule, it is not present in English gin. Every gin-distiller has a receipt of his own, which is usually kept a secret; hence the variety of flavours to be found in this spirit; as, the plain gin flavour, the Hollands flavour, the whiskey flavour, the smoky flavour, the Hollands flavour, the whiskey flavour, the smoky flavour, the flavouring of gin; among others may be mentioned sugar, bitter almonds, turpentine, creosote, lemon, cardamomas, caraways, caseia, garlic, Canada balsam, horseradish, grains of paradise, cayenno pepper, and several other herbs, seeds, fruits, &c.

GINGER. (See ZINGEER.)

GINGHAM, ging-hām (its Indian name), a cotton fabric, originally manufactured by the natives of India, from whom also it derived its name. It generally bears a coloured check pattern, which is not produced by dyeing or stamping the manufactured material, but by interweaving coloured threads. Formerly, all the gingham in use was imported into this country from India; but at the present time it is largely manufactured are known by different names in commerce; and umbrella gingham is woven with threads all of the same colour.

GINSENS. (See CAPANAX.)

of quadrupeds, as it is the largest of the Ruminant order. In points of resemblishes, the giraffs approaches the deer, the autislope, and the camel; and, besides this, has many singularities about it which are especially its own. In the length, slenderness, and firstbility of its neck, it surpasses all other quadrupeds, and peculiarities of conformation adapt it eminently for the life which it leads on the sandy desert. Its head resembles that of the camel, from the absence of a naked muzzle, and in the shape and organization of the nostrile, which are oblique and narrow apertures, defended by the hair which grows at their margins, and surrounded by cutaneous mescular fibres, by which the animal can close them at will. This is a beautiful provision of nature for the defence of the air-passages and the irritable membranes lining This is a because provision of materia to the element of the sir-passages and the irritable membranes liming the olfactory cavities, from the fine particles of sand which the storms of the desert raise up and whirl about in sufficienting clouds. The eyes of the girafic area

GIRAPPE.

laced as to take in a wider range of vision than those passed as to take in a wider range of vision that those of any other quadruped, and it is thus able to see an enemy in the rear as well as in the front when its head is elevated during the time that it is briwsing on its favourite assais plant. The weapons by which it defends itself are its horns and its hoofs. The forit defends itself are its horse and its hoofs. The lormer it does not wield by butting, as is the case with
other Cervide; but swings round with a lateral movement of the neck, and hits with them sideways: the
latter are very powerful; and sometimes a giraffe has
been known to prostrate a lion with a single kick. Its
motion in progressing is most peculiar; travelling, as
it does, in a sort of orab-like movement. It lifes both it does, in a sort of crab-like movement. It lifts both its hind and fore legs on each side of the body together, its hind and fore legs on each side of the body together, and its appearance when cantering is peculiar in the extreme. The tongue is formed to suit its habits of life, and is used to hook down the branches of trees which grow beyond the height at which its muzzle can reach. The two horus with which it is provided are peculiar to both sexes, the bony part of the same being articulated by a broad, rough, epiphysial basis to the oranium, and covered by a hairy tegument. It is mentioned in Brande's Dictionary, that "a giraffe more than two-thirds grown will est daily confinement eighteen pounds of clover-hay and eighteen pounds of a mixed vegetable diet, consisting of carrots, mangel-wurzel, baffley, split beans, and onions, and will drink four gallons of water. They copulate

in March. The female has four inguinal adders: she brings forth one young one at a birth, and the period of gestation is fifteen months. The new-born giraffe measures six feet from the fore hoofs to the top of the head, and in a few hours after birth it is able to follow the dam."

low the dam,"

GIRBER, gw'der (from Bax. gwdus, to bind), the
name given in Civ. Eng. and Arch. to long beams of
wood and iron, that are thrown across openings of considerable span, to support floors and the roadway of
bridges. Girders are of two kinds, simple and framed; bridges. Girders are of two kinds, simple and framed; the former being merely wooden beams, or beams of east or wrought iron; while the latter are beams of the above materials made of several pieces, put together in such a manner that they may be capable of offering a greater resistance to excessive pressure than a simple girder could exert. The depth and width of all girders must be proportioned to the greatest weight that is likely to be thrown on them, that they may be abbe to offer the greatest possible resistance to its pressure, with the least possible quantity of material. The strength of a girder is augmented by adding to its depth, rather than to its width, as a less capability of resistance increases directly as the width and as the square of its depth. If, for example, a beam of Norway deal that is three directly as the width and as the square of ins depts. If, for example, a beam of Norway deal that is three inches wide and six inches deep will bear a certain weight, a beam that is twice as wide will bear twice that weight; while one that is twice as deep will bear four times as much, and one that is twice as deep will bear twice as deep, eight times as much. The longer it is, the greater will be its flexibility; or, in other words, the content of the twice as deep, eight times as much. The longer at is, the greater will be its flexibility; or, in other words, if two beams of the same width and depth, but of which one is twice as long as the other, be supported at the ends, having equal weights suspended from their centres, the longer beam will exhibit a greater amount of deflection than the shorter one; the capability of resistance in griders of all kinds being inversely as the length. The manner in which the weight is thrown on a beam has considerable influence on its power of release the considerable influence on its power of rea beam has considerable influence on its power of ra-sistance. Thus a beam will not bear half as much, if all the weight be collected at its centre, as it will if the weight be distributed equally along its length. Beams will also bear a greater weight when their extremities are secured, or loaded with a weight of masonry, as in the case of graders stretching from wall to wall of a building, to support a floor. A dead uniform weight is less injurious to the power of resistance that a girder can exert, than a weight which is in motion; but it is found that the power of resistance of a beam loaded with a dead weight decreases considerably when it has sustained that weight for a long period of time. The amount of weight that should be thrown on a girder under any circumstances should never exceed one-third of the weight that would have to be applied to it in order to break it. Girders should also be shaped in accordance with the conditions under which they are to be loaded. Thus the upper surface of a girder supaccordance with the conditions under which they are to be loaded. Thus the upper surface of a girder supported at both end—what has to sustain a great weight at one point only, should be in the form of a parabola; while that of a beam supporting a uniform weight at all points, should be elliptic, the under surface being perfectly straight in both cases. Wrought and cast iron girders are made with flanges, or projecting edges of metal at the top and bottom. In cast-iron girders, the bottom flange must have a sactional area coult to six. mensus at the top and nottom. In cast-iron girders, the bottom flange must have a sectional area equal to six times the area of the top flange, as the power of cast iron to resist compression is about six times as great as its power to resist a drawing atrain; but in wroughtiron girders, on the contrary, the sectional area of the bettom them read he are to say that of the top area the area of the heater when the say that the these than the say that the these than the say that the these than the say that of the top the top the say that the these than the say that the the say that the say the say that the say that the say that the say the say that the say that the say that the say that the say the aron girders, on the contrary, the sectional area of the bottom flange need be only one-half of that of the top flange, as the power of wrought iron to resist compression is only half as much as its power to resist tension. In other points, the strength of iron girders varies in proportion to their depth.—Ref. Tate's Strength of Maderials; Rairburn's Cast and Wrought Iron for

Building Purposes.
GIBDLE, gir-dl (Ang.-Sax. gyrdel, from gyrden, to envirole; Gr. zone, Lat. cingulum), a band of leather, or some other substance, used in girding up the kins. It was more or less in common use among several of It was more or less in common use among severess of the nations of antiquity. In Scripture, the girding up-of the loins is frequently alluded to as being greatised by the Jews before undertaking a journey. Girdles of sackcloth were also sometimes worn as tokens of hu-miliation. Among the Greeks and Romans the girdle

Girondists

was a military ornament; and hence to deprive a soldier of his girdle was a mark of the deepest ignominy. The tunic of the Romans was also fastened by a girdle or belt shout the want, and it was regarded as very effeminate to uppear abroad with the tunic alackly or carelessle girdle. Hence girt came to denote diligence, activity, cleverness, and ungirt, idleness, effeminacy. The young women always wore a girdle, or sone, before marriage; and hence the phrase "Zonam solvers virgineam" was sometimes used to denote that ceremony. The girdle worn by Venus was called "cestus." Among the Romans the girdle served also as a purse; and in England it was formerly the practice for bankrupts, or insolvents, to give up their girdles in open court.

GENONDISES, je-ron-dists (Fr. Girondins), the name of a celebrated political party in France during the Revolution. They were so called from the department of Gironde, which the leaders of the party represented in the Legislative Assembly which met in the month of October, 1791. These were Verguiaud, Guadet, Gensonné, Grangeneuve, Ducos, &c., men of great oratorical powers, and who soon obtained great influence in the Assembly. Their political views, however, were not sound; and they did great mischief by their opposition to the constitutionalists; thus leaving the way open for the extreme democratic party. They were republicans, who took their political notions chiefly from the writings of the ancient Greeks, and succeeded in gaining many over to their side. For a time they had a majority in the Assembly, and the succeeded in gaining many over to their side. For a time they had a majority in the Assembly, and the king found himself obliged to select some of the more king found himself obliged to select some of the more moderate of the party to form his ministry; among whom were Roland, Servan, Clavière, and Dumouricz. For a time they seemed reconciled to monarchy; but at length the king found it necessary to dismiss them; a proceeding which led to the insurrection of the 20th of June, 1792. They, indeed, did what they could to oppose the massacres which followed; but their popularity and influence with the people was wholly gone. They subsequently endeavoured to stir up the provinces against the Parisian party, but without success. The demagogues of the city rose in arms against them, assailed the Convention, and demanded their imprisonment. They were accused, tried, and condemned.

assailed the Convention, and demanded their imprisonment. They were accused, tried, and condemned. On the 31st of October, twenty-one of them perished by the gaillotine, including Brissot, Vergniaud, Genconné, and Duoos; others perished afterwards; a fewescaped, and after the downfall of the Terroriats, again appeared in the Convention.—Ref. Lamartine's Ristoire des Girondins, 8 vols., Paris, 1847.

GLACIAL Deposits, gluis'e-al (Fr. glacial), in Geol., belong to the Pleistocene period, and consist chiefly of clays, sands, and gravels, sometimes stratified, sometimes rudely piled together, and containing great blocks of rock, which also sometimes occur scattered loasely over the bare rock-surface. These deposits, which have evidently been forzaed by the agency of glaciers, are called by various names; as, the "Great Northern Drift:" "Till" (in Scotland), a brown clay which have evidently been forrard by the agency of glaciers, are called by various names; as, the "Great Northern Drift;" "Till" (in Scotland), a brown clay with boulders; "Marls" in Wesford and Wickbow, where fossilierous marl is interstratified with sand and gravel; "Limestone Gravel" in central Ireland, chiefly consisting of pebbles of carboniferous limestone, heaped sometimes into narrow ridges forty to eighty feet high, and from one to twenty miles long, which are called "Escars;" the "Boulder Clay" in northern and central England; and "Drift" almost universally. The "Erratic Block Group" is another well-known name for these deposits. (See GLACIER, BOULDERS, DEIFF, PLEISTOCKER.)

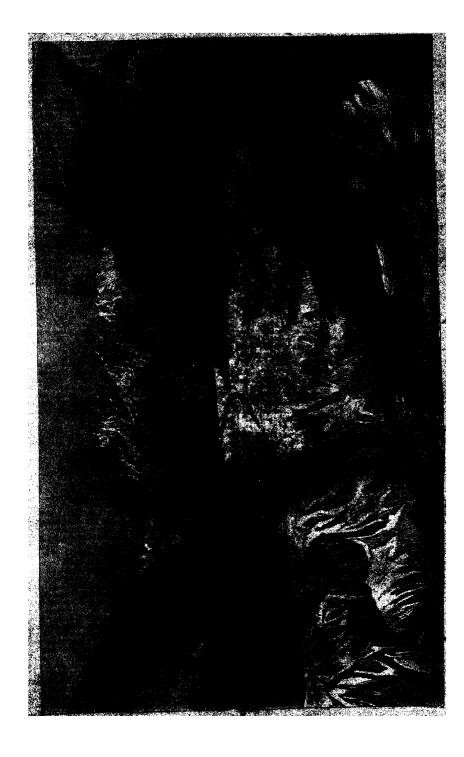

well-known name for these deposits. (ose Thables, Bouldess, Duirr, Flaismoekins.)
Glacies, glüs'-s-sr (Lat. glacies, ice), an accumulation of ice, or of anow and ice, formed in a valley or vavine of a snowy mountain. The average annual fall of snow in the region of the Swiss Alps, from 8,000 rau or snow in the region of the Swiss Alps, from 8,000 to 10,000 feet above the level of the sea, has been estimated at sixty feet; that is to any, sufficient snow descends in one year to form a bed of this thickness. The accumulation of snow on the high table-land is called the need, and is found to consist of layers of more or less everatibles can which diministration. called the nece, and is lound to consist of layers of more or less crystalline snow, which diminish in thickness as their depth increases. At a certain depth, these layers can scarcely be distinguished one from another, and still lower the substance of the neve passes into clear ice. The neve is the source of the 910

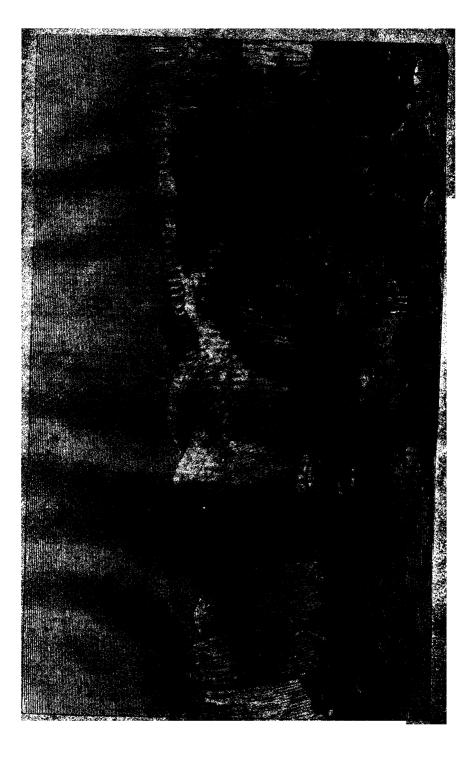

glaciers, or rivers of ice, which fill all the valleys radiating from the central mass of a great mountain. Sometimes valleys twenty miles long and three or four broad are filled up with ice to the depth of some 800 feet. Although apparently solid and stationary, glaciers more slowly down their valleys, and carry with them, either on the surface, frozen into their mass, or grinding and rubbing along the bottom, all the fragments, large and small, from blocks many tons in weight down to the finest sand and mud, that rain, and ice, and the friction of the moving glacier itself, detach from the adjacent rocks. The laws of this motion were first thoroughly investigated by Professor James Forbes, who was forced to admit that the ice-mass possesses a slight degree of plasticity, or a demicentificiality, by which it is enabled to flow down the valley just as a viscous substance, such as partially melted pitch, would flow. The researches of Professors Tyndall and Faraday have shown that ice may be plastic without being viscous, owing to its peculiar property dall and Faraday have shown that fee may be plastic without being viscous, owing to its pseudiar property of reuniting by the contact of adjoining surfaces after having been broken into fragments. (See REGELATION.) The motion of the glacier is not due to viscosity, as imagined by Forbes, but is the result of the minute, almost molecular, fracture and regelation of the ice particles, which move as if they were sand, continually thawing and re-freezing. The glaciers of the Alps, and probably those of ofter regions, descend to a vertical depth of nearly 4,000 feet below the line of perpetual snow, and into a warm climate. before the Alps, and probibly those of other regions, descend to a vertical depth of nearly 4,000 feet below the line of perpetual snow, and into a warm climate, before they finally melt away and leap forth as rivers of running water. The heap of materials of all sorts and sizes, which they deposit at their melting extremity, is called the moraine, a term which is also applied to the lines of blocks that are being carried along on the surface of the glacier. Combined with the avalance and the iccherg (see these words), the glacier is now, as it has been in ages past, one of the most important of geological agents. Professor Tyndall has lately advanced the theory that the present conformation of the Alps has been produced mainly by the action of ancient glaciers. All the great valleys have, in his opinion, been ploughed out by moving masses of ice; in other words, the glaciers have been the real excavators, and not, as usually supposed, mere accidental tenants of valleys previously formed by water denudation. The evidence of glaciers in any country during former epochs consists partly in the polished and grooved surfaces of the rocks over which they slid with their impested boulders and shingle; and partly by the peculiar contour and composition of the moraines, which differ materially from beds of diffusionings and polishings, together with the moraines, weathed boulders, bear evidence to the existence and detended boulders, bear evidence to the existence very distinct. In all the valleys of the Snowdon range, soratchings and polishings, together with the moraines and detached boulders, bear evidence to the existence of vast aluggish rivers of ice. At Plate LXI, is shown a drawing of the celebrated glacier known as the Mer de Glace; at Plate LXII, is given a drawing of the Glacier des Bois and the source of the Arveigon. Both these glaciers are in Switzerland.

GLACIS, glates (Fr.), in Mil., the inclined plane or alope that extends from the exterior of the covered way towards the open country. The great of the

supe that extends from the exterior of the covered way towards the open country. The creet of the glacis is about seven or eight feet above the terreplein of the covered way, which coincides with the natural level of the soil surrounding the fortifications. The slope itself extends about 150 feet from the covered slope itself extends about 150 feet from the covered way, having an inclination of one foot in twenty, or theresbouts, from the crest of the work to the natural surface of the ground. The glacis covers the masonry or reveturents of that part of the rampart which forms the searp of the ditch, and serves to hide it from the batteries of the enemy. It also conceals soldiers who are in the covered way from the view of the investing force, and protects them from their fire. A banquette in unually constructed in the covered way.

GLADIATORS, gläd-e-ai-tors (Lat.), a term applied in Antiq. to those porsons who fought, generally in the arena at Rome, for the entertainment of the spectators. The custom of gladiatorial combate was introduced into Rome from Asia, and some suppose that the reason of keeping up the diversion was to accustom the people to despise danger and death. The

origin of these combats seems to have been a custom in which many nations indulged, of sacrificing captives or prisoners of war to the smanes of the great men who had died in the campaign. Thus, Achilles, in the Iliad, is represented as sacrificing twelve young Trojans to the manes of Patroclus; and Encess, in the Encid, sends captives to Evander to be sacrificed at the funeral of his son Palles. In time it became the custom to sacrifice slaves at the funerals of all persons of distinction; but as it appeared barbarous to massacre them in cold blood, they were appointed to fight with one another, and endeavour to save their own lives by killing their adversaries. This took away somewhat of the horror of the spectacle, as there was a possibility of avoiding death by courage and skill. The diversion became every popular, and the profession of gladiator became an art, the masters of which were called landers by the Romans. They purchased and trained up slaves for the purpose, and then sold them to those who had charge of the gladiatorial exhibitions. At first the contests took place near the sepulchre or funeral pile of the déceased; but they were afterwards removed to the circus and amphitheatres, and became ordinary amusements. In process of time the Romans became so fond of these bloody entertainment that not only heirs coming into property, but all the principal magnistrates, presented the recole with shows origin of these combata seems to have been a custom that not only heirs coming into property, but all the principal magistrates, presented the people with shows of this nature in order to court their favour. The emperors also found it was much to their interest to provide gladiatorial displays. Titus exhibited a show provide gladiatoris displays. Titus exhibited a show of gladiators, wild beasts, and shem sea-fights, which lasted more than 100 days; and Trajan a similar solemnity, which continued for 123 days, during which time 5,000 pairs of gladiators were brought out. From slaves and freemen the inhuman sport at length spread slaves and freemen the inhuman sport at length spread to people of rank and condition; so that Augustus was obliged to issue a public edict that none of the senatorial order should become gladiators. The number of gladiators, however, increased, and the evil increased to such an extent, that Constantine issued a decree abolishing the gladiatorial shows, which, however, continued a favourite pastime till the reign of Honorius. On several occasions Rome was in danger through the On several occasions Rome was in danger through the large number of gladiators. One of the most memorable instances happened in the year 76 n.c., when seventy-four gladiators, headed by Spartacus, a Thracian, overcame their master at Capua, and fled to the mountains. There they were joined by runaway slaves and peasants, and soon became the terror of the country, and spread alarm almost to the gates of Rome. The war lasted three years, when Spartacus was slain by M. Crassus, after displaying much valour. Gladiators were classed according to the weapons which they used and the manner in which they fought. The Ordinarii fought averal together; the Eguites fought Ordinarii fought in pairs in the ordinary way; the Cateroarii fought several together; the Equites fought no horseback; the Retiarii used a fork, called a tridens, and a net, which they threw over their opponent, who was generally armod with a short sword and a shield: the Andabatæ fought blindfolded, the helmets which covered their heads having nospertures,—their ludicrous motions were very amusing to the spectators; and the Hoplomachi, who fought in complete armour; together with various others. All the gladiators were armour on the right arm, if nowhere else, and all wore helmets and carried shields, except the Rettarii. The Bestiarii, who fought with wild beasts for money, were on me right arm, it nowhere cise, and all wore helmets and carried shelds, except the Retariii. The Bestiarii, who fought with wild beasts for money, were not reckned as gladistors. When a gladistor was so severely wounded as not to be able to continue the fight, his antagonist stood over him pausing, until he should kill him or not. If he had fought well, the audience turned their thumbs downwards, to indicate that his life should be spared. If, however, he had neither shown courage nor address, they held up their thumbs downwards, they held up their thumbs, and the victor immediately passed his sword through the body of his fallen antagonist. Palms were awarded to the conqueror, and gladistors, or retiring through the body of his fallen antagonist. Palms were awarded to the conqueror, and gladistors, or retiring from horses infected is only one who has taken the infection. The best to shoot them at once, as they seld up their thumbs downwards, to indicate their discussion of the story of glanders is so strong, that all horses that have even gone near another affected is only one who has taken the infection. The best plant, therefore, with regard to horses infected is only one who has taken the infection. The best plant, therefore, with regard to horses infected is only one who has taken the infection. The best plant, therefore, with regard to horses infected is only one who has taken the infection. The best plant, therefore, with regard to horses infected is only one who has taken the infection. The best plant, therefore, with regard to horses infected is only one who has taken the infection. The best plant, therefore, with regard to horses infected is only one who has taken the infection. The best plant, therefore, with regard to horses infected is only one who has taken the infection. The best plant, therefore, with regard to horses infected is one wort them at once, as they seld one retain to spread the disease, and geard to horse infected is described with the diborres infected is only one who has taken t

of bas-reliefs illustrating clearly the mode of fightidal

of bas-relies illustrating cleary the mouse of against of the gladiators.

Gladiators, Glade-o'-lus (Lat. gladius, a sword, in allusion to the shape of the leaves), if Bot., a gen. of the nat. ord, iridaces, consisting of plants with ensiform leaves and very showy flowers, purple, red, or white. Many species and varieties are in outlivation thanks a decream of any and cardialis are the

white. Many species and varieties are in cultivation as border flowers. G. communis and cardinalis are the favourite species: the latter is a splendid plant, with scarlet flowers, spotted with white.

GLAND, glind (Lat. glans), in Anat., is an organ of the body, composed of blood-vessels, nerves, and absorbents, in which secretion is carried on; as the lacyrnal, mammary, and salivary glands. They are variously divided by anatomists, according to their structure or their contents. In form, glands are—1. Simple; consisting of small hollow follicles, covered with a peculiar membrane, and having a proper excretory duct; as the membrane, and having a proper excretory duct; as the mucous glands of the nose.—2. Compound; consisting mucous giands of the nose.—2. Compound; coffisisting of many simple glands, the excretory ducts of all of which meet in one common duct; as in the sebaceous glands of the face, &c.—3. Conglobate or lymphatic glands; composed of a texture of lymphatic vessels, connected together by cellular membrane.—4. Conglomerate; composed of numerous simple glands, with their ducts all entering into one common trunk; as the parotid and salivary glands. According to their con-tents, they are divided into mucous, sebaceous, lym-phatic, salival, and lacrymal. There are also what are termed ductiess glands, which resemble the others in external conformation, but differ from them in the in external conformation, but differ from them in the absence of any duct or opening for the removal of the secreted fluid, and indeed, few of them contain any secreted fluid. Glandular swellings are not unfrequent, especially in weak and scrofulous persons. They occur about the neck, or other parts of the body, are comparatively paniless, and of very alow growth, with little or no tendency to suppuration. In such cases, the system should be strengthened with tonics, and stimulants applied to the part: sea-bathing is also very beneficial. Glandular swellings also cour in certain diseases; as scarlet fever, &c. diseases; as scarlet fever, &c.

GLANDERS, glind'-ers (from gland), a disease in horses, which is attended with a copious discharge of horses, which is attended with a copious discharge of mucus from the nose, and which generally preves fatal to the animal affected. Scrolulous horses, on account of their weak constitution, are generally subject to glanders. The poison produces in the blood abnormal changes, which vitiate the fluid, and unfit for healthy nutrition. From the irritant nature of the morbid fluids passing through them, the lymphatic glands and vessels become inflamed, and lymph is deposited. This being of an unhealthy nature, soon softens, and extends to the skin overlying the part, and ulperating extends to the skin overlying the part, and ulcerating sores are formed. On the surface of the more vascular sores are formed. On the surface of the more vascular nucous membranes effusions of tubercular matter are also poured out. These bring on inflammation, and degenerate into chancrous ulcers, generally un the mucous membranes of the nostrils in extreme cases of mucous memoranee of the nostrils in catterine cases or disease. It is stated in Johnson: "Farmer's Encyclopadia," that blue vitriol (sulphate of copper) in drachm doses of thin gruel, has been given with success as a remedy in some cases, and that the nostrils should also be washed with a solution of lime. Glanders is often communicated to the human system from horses affected with the disease, and generally ends in death

Glasgow, University or

Glasgow, University or, glda-go, was founded
by William Turnbull, the then bishop of Glasgow, in 1451, in terms of a bull obtained from
Pope Nicholas V. in the preceding year. Two
years after, King James II. conferred upon it,
by royal charter, certain important privileges.
"This miversity," says Dr. Reid, "came into the
world as naked as every individual doss;" it had no
property in lands or houses, besing chiefly dependent
upon the exertions of the bishop and elergy of Glasgow.
In 1459, however, James Lord Hamilton bequeathed
some property in Chasgow for the use of the College of
Arts; and a few years later, Thomas Arthurile be
queathed another tenement to the college. During
the period of the Reformation, this university was althe period of the Reformation, this university was almost completely annihilated; but in 1560, Queen Mary bestowed upon it the manse and church of the Preach James VI. endowed it with the rectory and in 1977, James VI. endowed it with the rectory and vicarage of the parish of Govan. Since that time the college has continued to flourish, and has given forth many learned men. The number of matriculated students now avemen. The number of matriculated students now averages about 1,200. It possesses faculties of artss law, medicine; and theology, with chairs for Latin, Greek, mathematics, logic, natural and moral philosophy, English language and literature, natural history, botany, chemistry, anatomy, physiology, materia medica, practice of physic, chinical surgery and medicine, midwifery, surgery, divinity, church history, Oriental languages, biblical criticism, civil law, conveyancing, civil engineering, and practical astronomy. Connected with the university are the library, comprising upwards of 100,000 volumes; the Hunterian museum, bequeathed by the celebrated Dr. William Hunter, comprising a valuable collection of anatomical preparations, coins, medals, &c.;—an observatory, and preparations, coins, medals, &c.;—an observatory, and a botanical garden. The office-bearers of the universty consist of a chancellor, rector, principal, and dean of faculties. It possesses a number of bursaries for the support of poor students, and ten exhibitions at Oxford, founded by John Suell, a native of Ayrshire, Oxford, founded by John Suell, a native of Ayrantre, who, in 1688, bequeathed a considerable estate in Warwickshire for the support of Scotch students at Balliol College, Oxford, who had studied for some years at the University of Glasgow.

GLASS, GLASS MANUFACTURE, glass (Sex. glass).—
The composition of this important substance differs ma-

the composition of this important substance diters materially, according to the use for which it is intended. It generally contains the silicates of potash, sodard lime, baryta, magnesis, alumina, and land, coloured by small portions of iron, manganese, cobalt, tranium, copper, or gold. These different varieties must not be considered as definite chemical compounds, but as a mixture of silicates with an excess of silica. The best glass, however, is found to be that which contains the minimum of uncombined silics. The celebrated Bohemian glass, so much valued in the laboratory for its Boheman glass, so much valued in the laboratory for its hardness and infusibility, contains the silicates of potash and lime in predominant proportions. The more fusible Bohemian glass, which is used for ornamental purposes, contains, in addition, anotable quantity of silicate of alumina. French plate glass and ordinary window-glass consist principally of the silicates of sods and cate of alumina. French plate-glass and ordinary window-glass consist principally of the silicates of sods and lime, soda producing a more liquid compound than potach. The ingredients used in the well-known French plate-glass from St. Gobain are 300 parts of white quartzose sand, 100 of any carbonate of soda, 43 of slaked lime, and 300 of cullet, i.e., fragments of broken glass of previous meltings. The fuel employed in the furnace is wood. Ordinary window-glass is made of a mixture of 100 parts sand, 35 or 40 of chalk, 30 or 35 of soda-ash, and from 50 to 160 of cullet. The inferior opaque or somi-opaque kinds of glass used for wine-bottles, carboys, and other articles in which inferior opaque or somi-opaque kinds of glass used for wine-bottles, carboys, and other articles in which tagnessarrow is no object, consist of the silicates of alumina, iron, lime, magnesia, and soda or potash, mixed in varying proportions. Common bottle-glass is made from sand 100 parts, soapmakere' waste 90, gas-lime 80, common clay 5, and rock-talt 3. Bottle-glass contains a less amounts of silica than any of the other varieties. The ordinary white glass used for table purposes in this country is a colourless silicate of potash and lead, and is commonly known as fint-glass, although all glass has just as good a right to this title. The oxide of lead contained in it gives it a

density, softness, fusibility, and brilliancy, qualities which render it peculiarly valuable for the purposes to which it is applied. From its high refractive and dispersive power, it is much employed for optical purposes. Optical glass is made with great care from the purest materials. A good optical glass may be made from 100 purts of pure sand, 100 of minium, and 30 of refined pearl-ash. In making fiint-glass, the melting-pots used are made of the finest Stourbridge clay, mixed with a certain quantity of old pots. The mass is worked up with water, and allowed to remain in this condition for times or four months. It is then made into pots, which are arched over at the top, having a side-opening by which the glass may be withdrawn. They are placed in the furnace in such a manner that the products of combustion may not have access to They are placed in the turnace in such a manner that the products of combustion may not have access to the hole, which would endanger the purity of the glass by reducing the lead to the metallic state. By increasing the quantity of lead, a very transparent glass, with still higher refracting power, is produced, termed pasts or strass, which is used in the white state for cutting into false brilliants, and, in combination with various metallic oxides, for imitating gems and precious stones. Coloured class is made by combining crownstones. stones. Coloured glass is made by combining crown-glass with various metallic oxides, which are dissolved by the glass in small quantities. Protoxide of iron produces green; but sesquioxide of iron has but little produces green; but sesquioxide of iron has but little colouring power, except when present in large quantities, when it gives a yellow tinge to the glass. The contrary is the case with the oxides of manganese, the protoxides producing no tint, while the sesquioxide colours the glass purple or violet. Advantage of this is taken in making colourless windowglass, in which protoxide of iron is a constant impurity. By adding a small portion of black oxide of manganese, the sesquioxide of iron and the protoxide of manganese are formed, neither of which has any colorific properties. It frequently happens that a slight excess of manganese is added; in which case the resulting class turns purple when exposed to the light. Oxide of chromium gives an emerald-green tinge; oxide of cobalt, a deep blue; emerald-green tinge; oxide of cobalt, a deep blue; protoxide of copper, a green; deutoxide, a ruby-red; oxide of uranium, an opalescent greenish-yellow; gold with oxide of tin, a ruby-red; and the oxides of silver with oxide of tin, a ruby-red; and the oxides of silver and antimony, varying shades of yellow. Coloured glass is of two kinds,—flashed glass and pot-metal. Flashed glass has only a superficial coating of coloured material, while pot-metal is coloured throughout the mass. Class may be divided technologically into two kinds,—cast glass and blown glass. The former kind comprehends British plate, which is east and polished; optical glass; and the glass used for heavy domestic utensils, which is made by a combined process of blowing and casting. Blown glass includes ordinary crown and sheet glass, and the lighter glass used for table purposes. British plate is cost in large sheets upon iron tables provided with a ledge to prevent the moiten metal from running off. Were the glass allowed to cool suddenly, it would fly in pieces, from unequal tension, at the slightest jar or blow. It has, therefore, to be cooled or annealed very gradually in an oven or furnace, after which two sheets are placed together, with a layer of polishing pasts between them, together, with a layer of polishing pasts between them, and rubbed backwards and forwards in every direction and rabbed backwards and forwards in every direction until perfectly smooth, the final polish being given to it by women's hands. Window glass is made by two different processes, one of which consists in blowing a large bubble of glass, reheating it and causing the opposite sides to coalesce into a flat disc, by twiring it like a mop while still in a melting state. Glass made the opposite sides to coalesce into a flat disc, by twitling it like a mop while still in a melting state. Glass made by this process is called exown glass. Ghest glass is made by first blowing a long cylinder and cutting off the two onds; the remaining tube is cut down the middle with a diamond, reheated, and opened on an iron table into a flat sheet. This, when polished, forms the patent plate of commerce. Since the removal of the excise duties on glass in 1845, this article has been gradually improved in every direction, until it has reached a state of perfection beyond which it seems difficult to go. The acertions made by Messrs. Chance of Birmingham have principally brought about this result, and now a piece of table glass can be bought for a few pence that but a few years ago would have cost as many shillings. The introduction of glass-engraging has raised up quite a

new branch of art, artistic ornamentation being now applied to table glass of so high a degree of excellence that a small vase-but a few inches high has been sold for two hundred guiness. The introduction of gas glass-furnaces (see Furnaca) will do much to lower the price of glass, and still further improve its quality; and even now this wonderful material is produced at so low a rate that it is mased for roofing houses and cellars at little more than the cost of ordinary roofing materials. (For fuller particulars concerning the manufacture, see Ure's Diot. of Arts, article Glass.)

Guass-nownes, the process by which fint, crown, sheet, and other kinds of glass, are manufactured. The tools employed in glass-blowing are simple, and have continued in use with elight alteration for more than two hundred years. That and skill supply the place of more claborate sids. The principal instrument used is the blowing-tube, which is made of from half an inch to an inch in diameter. It is smaller at the mouth end than at the end which gathers the at the mouth end than at the end which gathers the metal. In the manufacture of flint glass, the blowing tube, being heated at the end nearly to reduess, is introduced into the pot of fused glass, or metal as it is called, which immediately adheres to it; and by turning called, which immediately adheres to it; and by turning it round, the workman can gather up as much metal as he requires. If a large quantity be wanted, the first gathering is allowed to cool by exposure to the air, and when somewhat solidilied, another gathering of metal is made, or even a third and fourth. The utensil to be made is then finished by a process combining blowing, manipulating, annealing, cutting, &c. (See Glass Manuvacture.)
Glass, Expusing on, the art of producing designs

GLASS, ETCHING ON, the art of producing designs upon glass, by the corrosive power of hydro-fluoric acid. In order to effect this operation, the glass is covered with a thin ground of bees-wax; the design is then drawn upon it with the needle, as in etching upon copper. Sulphuric acid is afterwards poured on, and fluor spar or fluoric acid sprinkled on it. The hydrofluor spar or fluorio acid sprinkled on it. The hydro-fluorio acid which is disengaged acts powerfully upon the exposed portion of the glass, while fumes of fluo-silicic acid are liberated. After four or five hours the acid is removed, and the bees-wax removed from the glass with oil of turpentine. The glass is then found to be stched with the design required. The operation may be reversed by drawing the design upon the glass with a mixture of bees-wax and turpentine, and then subjective it to the action of hydro-fluorie said subjecting it to the action of hydro-fluoric acid.

GLASS OF ANTIMONY, in Chem., a transparent glass of a red colour, formed by fusing tersulphide of anti-mony in the open air. It is an oxysulphide of anti-mony, containing eight parts of oxide and one of sulphide.

GLASS-PAINTING, the art of painting designs upon ass, either stained or colourless, with substances glass, either stained or colouriess, who consisting usually of metallic oxides combined with a Whan subjected to a great heat, consisting usually of metallic oxides combined with a vitroous vehicle. When subjected to a great heat, the colours thus applied become permanently united with the surface of the glass. Fainted glass differs materially from stained glass, athlough the terms are considered synonymous. In stained glass, however, the substance of the glass itself has been coloured in the process of manufacture. The art of making coloured glass has been long known. It was introduced into Greace and Rome from Assertis and Error. coloured glass has been long known. It was intro-duced into Greece and Rome from Assyria and Egypt. Byzantine Greeks appear to have been the first persons who practised painting upon glass, and from Byzan-tium the art passed into the West of Europe, by way of Venice and Marseilles. In France, the art of glass-painting was practised with great success during the 12th century. After that time painted glass windows were regarded as essential in religious edifices of any pretenzion. Painted windows of the 13th century abound in France Garmany, and England, and belong pretension. Feinted windows of the 19th century abound in France, Germany, and England, and belong to the First Pointed, or Early English, style of architecture. The painted glass of the 14th century was more vivid in colour, with greater breadth in style, and more careful painting, than that of the preceding century. It was, however, less pure in conception, and not so strictly subordinate to the architectural effects. not so street, subordanies to the stremmentary a great change took piace. The windows became more individualised, and still less dependent upon the architecture. The designs were larger, and began to be treated as pictures.

After the 15th century, when Gothic architecture was declining, the medieval spirit departed from the art of painting on glass, and palages and domestic buildings began to be ornamented with painted glass windows, as well as churches. Glass began to be treated as if it were cauvas or panel, and the works of Raffaelle and other celebrated artists were either copied or imitated. The results were not good. From that period, glass-painting declined more and more, and, until within late years, has never shown any symptoms of revival. The method by which glass-painting is now practised differs in different places; but the general plan is as follows, for a small work on a single plate of glass.—A careful cartoon, the size of the painting, having been procured, the glass is laid out, a tracing made from it, and the outline is carefully traced on the glass, with black or brown, composed of a very fasible viterous flux, coloured with a metallic cxide, and ground extremely fine in an essential cil. Those parts After the 15th century, when Gothic architecture was fusible vitreous flux, coloured with a metallic oxide, and ground extremely fine in an essential oil. Those parts which are intended to be yellow, orange, or red, are then coated according to the tint required, with a mixture composed of an alloy of silver and antimony, ground up with the red oxide which is obtained by subjecting sulphate of iron to a red heat. The glass is then exposed in a furnace to a red heat, in which the tracing colour is fused, and adheres permanently to the glass. The mixture of silver and antimony colours the glass, but does not melt; so that the oxide of iron may be brushed off in the state of dry powder, leaving the glass coloured, but transparent. The other tints, composed of a very fasible class, coloured with metallic may be brushed off in the state of dry powder, leaving the glass coloured, but transparent. The other tints, composed of a very fusible glass, coloured with metallic oxides, are then added, and the whole once more ex-posed to heat. In most cases, the glass is heated, or "fired," as it is called, between the application of each colour. In making a painted window, many pieces of glass are fixed together in a leaden framework, great care being taken to arrange the several compartments from the narroon. from the cartoon.

from the cartoon.

GLASS, SOLVELS, in Chem., an impure silicate prepared by melting 8 parts of carbonate of soda or 10 of carbonate of potash with 15 of pure quarts and one of charcoal. The charcoal assists in decomposing the carbonate, and a black glass is formed, soluble in five or six times its weight of boiling water. It is used in dyeing, to impart incombustibility to wood and woven fabrics, as a varnish to preserve stone, as a vehicle in freeco-painting, and in the manufacture of soap. instead of rosin. of soap, instead of rosin.

GLASSES, MUSICAL, glas'-ses, an instrument of music, composed of a number of drinking-glasses, tuned by filling them more or less with water, and played upon by rubbing them with the end of the finger damped. The smaller the quantity of water contained in a glass, the lower is its tone: hence, it is evident that by procuring a number of glasses, exactly alike in size and shape, and putting a certain amount of water in each, suppe, and putting a certain amount of water in each, a complete scale may be formed. The skill, or rather trick of performing on these glasses, consists in producing instantly the required vibration, by a gentle and rapid action of the finger upon their edges. Mr. Pocherich, of Ireland, is said to have been the first who thempt of producing makes he this mann. who thought of producing music by this means. The instrument called the harmonica had its origin in the

instrument caused the harmonica had its origin in the musical glasses. (See Harnonica.)

Grassites, glass'sies, the name of a religious sect, which sprang up in Scotland about the year 1729, and was so called after its founder, the Rev. John Glass, who was originally a minister of the Church of Scotland, but was deposed by the General Assembly for holding printing contrasts the standard of the harmonical sections. but was deposed by the General Assembly for holding opinions contrary to the standards of the church. Ho fully explained his opinions in a tract, entitled "The Testimony of the King of Martyrs concerning his Kingdom." He was opposed to all national establishments for the support of religion, and advocated a system of independent church government. In fact, his views on this subject approached vary nearly those maintained by the Congregationalists. One of his principal disciples was Robert Sandeman, who formed a congregation in London in 1762, and, after him, this seet in England hears the name of Sandemanians. The leading tenets of the Glassites, or Sandemanians, relate to the efficacy of the atonement and the nature of faith. They hold that "the bare death of Christ, without a deed or thought on the part of man, is sufficient to present the chief of ginners apottess before

God;" and that "faith is no more than a simple assent to the divine testimony, passively received by the understanding." They maintain the necessity of a plurality of bishops, of teaching elders, in each church, but do not consider the want of learning, or employment in worldly business, any disqualification for this office. They also observe certain peculiar prectices, supposed by them to have been prevalent amongst the primitive Christians; such as weekly sacraments, love-feasts, washing each other's feet, the kias of charity, the use of lots; and in general, they attempt to carry out literally, as far as possible, the rules of Scripture. They contribute largely of their goods to the church and to the poor. For a long time they have been decreasing in numbers, and according to the census of 1851, there were only six small congregations of them in England, and a like number in Scotland; the aggregate number of sittings in all the English chapels being gate number of sittings in all the English chapels being estimated at less than 1,000.

GLAUBER'S SALT, glow'-ber (after Glauber), in Chem., the old name for sulphate of sods. (See SODA, SUL-

PHATE OF.) GLAING, glai'-sing (Ang.-Sax.), a term applied to the insertion of panes of glass into the sashbars of window-frames, and a peculiar method of polishing cutlery, as well as to the art of coating articles of earthenware and porcelain with a vitreous class this private them. glaze which gives them a smooth, polished, and us-trous surface. The term is also used in Paint, with reference to the employment of varnishes and certain reference to the employment of variances and certain transparent colours termed glazing colours; and in the culinary art, to the use of white of egg, to give a smooth and shining exterior to pastry and other articles intended for the table. In glazing earthen-ware, the ingredients that are used consist of red lead, white lead, felspar, ground flints, ground flint glass, Cornish stone and clay, sods, nitre, and borax. Various compositions are made for glazing, by mingling some of these substances together in different proporsome of these substances together in different propor-tions, according to the nature of the material which is tions, according to the nature of the material which is to be coated and the purpose for which the article is intended. Thus, in the glaze for common earthenware, white lead and ground flints predominate; in that for porcelain, felspar, borax, nitre, soda, Cornish clay and sand, are used; and for stoneware, red lead, white lead, and ground flints are mingled with the ingredients used for porcelain. For lignig chemical retorts, sand, potash, lime, and nitre are used, without any admixture of lead. The substances of which these glazes are composed are mixed with water, until they assume the consistency of crosm. When the mixture is perfectly ready for use, the ware is dipped into it, and afterwards subjected to the action of heat in an oven, which converts the liquid coating into a solid viterous glaze. (See EARTHENWARE.) into a solid vitreous glaze. (See EARTHENWARE.)
Metal-glazing is the production of a brilliant polish on outlery and steel goods, as well as articles made of brass, tortoise-shell, horn, ivory, and white metals, by means of wooden wheels from \$\frac{1}{2}\$ into four inches in width, and from four inches to two feet in diameter, the edges of which are covered with leather coated with emery-powder moistened with water. Other wheels are also used in polishing, coated with thick buff-leather, which is covered with a mixture of fine sand and water, or rotten-stone and oil, according to sand and water, or rotten-stone and on, according to the nature of the material which requires to be polished. The final polish is given with a wheel, the leather covering of which is sprinkled with crocus or metallic powder, in a dry state. Stones are polished by lapidaries in a similar manner, with wooden wheels, by lapidaries in a similar manner, with wooden wheels, which have emery spread on their edges. In window-glazing, the glass is cut to the required size with a glazier's dismond, and fastened to the sash-bars with a mixture of whiting and linseed oil, called putty, which hardens after having been exposed to the air for a few days, and retains the glass in its proper position. Before the erection of the Crystal Palace, the duke of Devonshire's conservatories at Chatsworth were the largest structures made of glass in this country, but they were eclipsed completely by the former building, in which 82,280 square yards of glass were used in panet which measured 49 inches in length by 10 inches as breadth.

Glesking, glesn-ing i Fr. claner. to glesn). was an

GLEANING, glean-ing (Fr. glaner, to glean), was an established practice among the Jews, and was sanc-

tioned by the law of Moses, who enjoins them, when they reap the harvest, not wholly to reap the corners of the field, nor gather the gleanings, which were to be left for the poor and the stranger, as were also the gleanings of the vineyard; for they were not to gather every grape. (Levit. xix. 9, 10.) In modern times there exists a very general feeling in favour of gleaning; and in England it is popularly regarded as a right which an owner or occupier cannot oppose, and that the poor who enter a field for this purpose are not guilty of trespass. The act, however, has been decided to be illegal, though the practice still prevails all over England of allowing the poor to glean the fields after they are reaped.

England of allowing the poor to give the next seven they are respect.

GLEBE, glebe (Lat. gleba, a lump of earth), in Law, is the land belonging to a parish church.

GLEE, glee (Sax. gleba, a vocal composition in three or four parts, generally consisting of more than one movement, the subject of which, notwithstanding the received sense of the word gles, may be either gay, tender, or grave. The term was not applied to vocal concerted music until long after the modrigal. The concerted music until long after the madrigat. The early glees were nothing but vocal music in parts, in which the singers began and ended together, singing the same words. Gradually, however, they became improved, and the play of words and phrases introduced. Certain words were elongated in musical expression, and points were taken up after the manner of the catch.

ner of the catch.

GUERMEN, glee'-men, a name-given by the Saxons before the Conquest to those who were afterwards called "minstrels." Their art consisted not only in heing the poets and historians of their times, but they were also buffoons, rhymers, singers, storytellers, and jugglers, all these branches being sometimes filled by one man; but oftener by several. They were the immediate successors of the ancient bards. Among the early Saxons, who came to England professedly to aid the Britons against the Picts and Caledonians, they were divided into two classes, distinguished by two supellations, the one signifying merrymakers, and the appellations, the one signifying merrymakers, and the

appellations, the one signifying meas, cotter, harpers.

Generoes, Massacre of, glen'-ko, in the history of Scotland, is an atrocious deed which was perpetrated by the regiment of Campbell of Glenlyon upon a tribe of the Macdonalds, who inhabited the lonely valley of Glencee, in the district of Lora, Argyleshire. After the revolution of 1688, many of the Scottish clans continued in arms against the new monarchy, and in August, 1691, a proclamation was issued by the government promising pardon to all who should lay down their arms or tender their submission before the lat of January, 1692. Many of the chiefs submitted and tendered their allegiance within the prescribed time. their arms or tender their submission before the lat of January, 1692. Many of the chiefs submitted and tendered their allegiance within the prescribed time. Among others, the aged Macdonald, or Maclan, of Glencoe, repaired to J Fort William, and Maclan, of submission, on the Slat of December; but the officer in command, not being authorized to receive it, referred him to the sheriff at Inversry. The journey was long and in the depth of winter; but the old man made what haste he ostild, and on the 6th of January, 1692, took the oath of Allegiance. The news that Mac Ian had not submitted within the prescribed time was, away Macaulay. "received with cruel joy by three says Macauley, "received with cruel joy by three powerful Scotohmen who were then at the English court,"—Breadsbane, Argyle, and the Master of Stair; the two former being hereditary enemies of the Maconcalds. The news of their submission was concealed, and the Master of Stair, who was secretary cealed, and the Master of Stair, who was secretary of state for Scotland, by representing to King William that the Macdonalds of Glenove still held out, obtained an order from the king for their extirpation. On February, 1692, a body of soldiers, 120 in number, under the command of Campbell of Glenlyon, were sent to occupy Glenove. They came professing friendship, and were received with the kindest hospitality by the people. On the evening of the 12th of February, the officers supped at Macdonald's house, and played cards with himself and family. The following morning at five o'clock was fixed for the bloody deed. Lieutenant Lindsay and a party of soldiers returned to the old chief's house, knocked, and were admitted. Macdonald rose from his bed to receive them, and willed ordering his servants to bring some refreshment for them, he was shot through the head. Two of his Globe

attendants were slain with him, and his wife received such cruel treatment that she died on the following day. Like bugchery took place in the other houses. The intention was to slaughter the whole tribe; but owing to the inclemency of the weather, a detachment of soldiers sent to guard the outlets of the valley did not arrive in time, and about three-fourths of the people escaped to the mountains, where many of the women and children perished with cold and hunger. "About thirty corpees," says Macaulay, "lay wallowing in blood on the dunghills before the doors. One or ing in plood on the aungulus before the doors. One or two women were seen among the number, and a yet mere fearful and piteous sight,—a little hand which had been lopped off in the tunuit of the butchery from some infant." The deserted hamlets were then set on fire; so that, when the wretched inhabitants returned, they found no place to receive them. The matter was attempted to be kept as private as possible, and various attempted to be kept as private as possible, and various attempts were made to conceal the truth, so that it was nearly a year after the crime was committed before it was published to the world. At length the popular cry became so great on this subject, that a commission was nominated in May, 1695, to investigate the whole matter. The report was laid before the house of the factitish and the way of the statement of the statemen Scottish parliament on the 23rd of June; and though it contains a clear and just statement of the circumstances, yet no punishment was inflicted on the au-thors of the crime. A graphic account of the massa-cre of Glencoe is given by Macaulay in his History of or of Glencoe is given by Macaulay in his History of England, vol. iv., and Campbell has made it the subject of a poem, "The "Pilgrim of Glencoe." A writer in Blackwood's Magazine for July, 1859, criticises severely Lord Macaulay's account of the massacre, whom he accuses of partiality in attempting to screen William; and concludes that the king's "signature was affixed to the order with full knowledge of the facts, and that his intention was to strike terror into the Highlanders by the 'extirpation' of a clan too weak to offer any formidable resistance, but important enough to serve as a formidable example."

GLOBE, globe (Lat. globus, Fr. globe), a name that is commonly applied to any spherical body, but more especially to the earth, and to the spheres on which representations of the earth's surface, and the relative position of the heavenly bodies, are delineated. These are respectively termed the terrestrial and celestial globe.

are respectively termed the terrestrial and celestial globe.
GLODE-MAKING, the art of making spheres, on which the surface of the earth and the field of the heavens, as it appears to our view, are represented. It is an operation requiring great care and nicety throughout the entire process. A spherical mould, which is generally turned out of a piece of hard close-grained wood, with wires projecting from diametrically opposite points, to represent the earth's axis and poles, is first covered with paper tightly pressed all over its surface. On this several layers of paper are pasted, one above another, until a pasteboard shell of sufficient thickness has been formed about the mould. This shell is then divided into two equal hemispheres, in a line corresponding to that of the equator of the globe, when it is completed. The edges of these hemispheres, which are reseally removed from the mould, in consequence of the first coating not having been pasted to it, are fastened to a piece of wood, corresponding in length with the internal diameter of the sphere, or two pieces of wood joined at right angles to each other, if the globe be large, after which they are securely glued togother, a wire being passed through the sphere and the wood in the centre, to form the poles of the future globe. Several coatings of plaster, made of whiting, oil, and glue, are then applied in succession, until the surface of the sphere presents a perfectly smooth and even appearance. During this part of the process, care is taken to make the sphere revolve easily and freely about its axis, and with regularity, by increasing or diminishing the weight of plaster at any point where it may be necessary. The lines of latitude and longitude that are necessary to guide the manufacturer in putting on the external covering are next drawn on its surface by the aid of a beam compass, and the sphere is now ready to be coated with goven of thin but tough putting on the external covering are next drawn on its surface by the aid of a beam compass, and the sphere is now ready to be coated with gores of thin but tough or paper, on which the outlines of the principal features of the earth's surface, and the names of the different explained in alphabetical order.—In Jurisprudence, parts of the land and water, have been printed from

CHORS

plates prepared by the engraver. The gores for globes of ordinary size are generally twelve in number, each embracing an extent of 30° of longitude along the equaembracing an extent of 80° of longitude along the equator, and extending to about the 67th parallel of latitude north and south of that line. The spaces left uncovered about the poles are covered with circular pieces of paper, extending as far as the arctic and antarctic circles. Great skill is requisite in pasting on the gores, to prevent the edges from overlapping. The globe is afterwards coloured and varnished, and the extremities of the axis are inserted in the ends of a semicircular meridian ring of brass in small globes, and of iron in large globes, made for school purposes, divided into 180 degrees, within which the globe revolves on its axis, and by means of which the latitude and longitude of any place on the globe's surface can be determined and read off. The metal meridian moves freely in a and read off. The metal meridian moves freely in a wooden hemisphere-frame, on which the astronomical horizon is represented by a broad ring which surrounds the globe in a horizontal plane, dividing it into two equal parts. This ring, called the wooden horizon, is covered with paper divided into 360 degrees and compartments of 30 degrees each, marked grees and compartments of 30 degrees each, marked withathe signs of the zodiac, and other things requisite for working problems on the terrestrial and celestial globes. Gibbes are made of all sizes, from three to thirty-six inches in diameter, eighteen inches being the diameter of globes of the ordinary size. They are sometimes made of paper, and constructed in such a manner that they may be folded up and laid saide when not in use. Globes of this description, for schools and public lectures, have been made measuring as much as ten feet in diameter. Embossed globes, or globes having the land raised in relief on the surface, are made in moulds. Globes have also been made of gutta-peroha, which can be taken to pieces and put

are made in moulds. Globes have also been made of gutta-percha, which can be taken to pieces and put together again at pleasure.

GLOBULARIA, glo'-bu-lad'-re-d, in Bot., a gen. of Selaginacea. The species are European shrubs and herbs. The leaves of G. Alspum form the wild senna of Germany, which have been sometimes employed to adultants annual same. adulterate senna-leaves. In small doses they act as a tonic, and in full doses as a safe, mild, and efficient purgative.

purgative.

GLOBULE PROJECTION, glob's-lar, the name more particularly applied to a kind of projection, very seldom used in man-making, in which the eye is supposed to be situated at a point which is distant from the part of the globe that is represented by one half of the chord of an arc of 90°. In this description of projection most of the great circles that appear on the map take the form of ellipses.

GLOBULE, glob'sule (Lat. globulus, a little globe), a small particle of matter of a spherical form. The term is more particularly applied to the microscopic particles which float about in the transparent serum of blood.

GLOBULIN, glob'sules (Lat. globulus), a term applied

blood.
GLOBULIN, glob'-u-lin (Lat. globulus), a term applied in Org. Chem. to one of the protein bodies, or albuminates, when associated with hamatin. As hæmatoglobulin it forms the principal ingredient of the blood globules; mixed with albumen, it is also found in the cells of the crystalline lens of the eye, and is then distinguished by the name of crystallin. Although closely resembling albumen in many of its relations, it differs from that substance in being precipitated from seid and alkaline solutions when perfectly neutralized. It is also, when in solution, completely precipitated by carbonic acid gas.
GLOMEBULE. (See INFLORESCENCE.)
GLOBIA IN EXCELSIS, glo'-re-a in else-sel'-sis (Lat., glory to God in the highest), is the name of a hymn in the communion service of the Church of England, and is so called from the words with which it begins. It is founded on the hymn of the Angels, given in Luke ii.

founded on the hymn of the Angels, given in Luke ii. 14, and is very ancient, appearing nearly as now used in the Apostolic Constitutions. In the Roman Missal it stands at the beginning of the office for the communion.

of the Justinian code, which were generally written between the lines of the text and on the margin, and between the lines of the text and on the margin, and were hence called glosses interbineers and glosses more sinales. These glosses were sometimes held to be of equal authority with the text itself. Accurains, who died about 1260, collected and arranged the glosses of his predecessors. The practice of introducing glosses was also adopted with the books of the cason law. Grossa, or Grorra, glos-så, glot-så, glot-så, glot-så, nanat, is a name given to the tongue, and forms part of the name of various parts connected with that organ. The glosso-pharyngeal nerves are the ninth pair of nerves, rising from the processes of the cerebellum, and terminating by numerous branches in the muscles of the tongue and larynx.

Grosserts, glos-si-sis (Gr.), in Surg., is applied to

the tongue and larynx.

Glossitts, glos-si'-tis (Gr.), in Surg., is applied to inflammation of the tongue. It may result from various causes; as mechanical injury, exposure to cold, the use of mercury, &c. The tongue becomes greatly swollen, and is painful to the touch; respiration and deglutition are much interfered with, and one of the chief dangers of the attack is suffoctation. In mild cases, the application of leoches to the part, with the use of purgatives, will afford relief; but in the more severe forms the knife is to be freely used, and pretty deep ionisions to be made into the indiamed part, which will afford almost instantaneous relief.

GLOTTIS, glot'-tis (Gr.), in Anat., is the name given to the superior opening of the larynx, situated immediately behind the root of the tongue, and covered by

distely behind the root of the tongue, and covered by the epiglottis. (See LARYEX.)

GLOVE, glue (Sar. glof), is a covering for the hand, which is divided into compartments for each separate finger. Xenophon asserts that the Persians used gloves in cold weather, and makes a charge against them, on that account, for their luxurious habits. They were in carly use in England, as is learned by their Saxon name; and in the middle ages they were decorated with gold and precious stones, and formed a costly article in the dress of kings, nobles, and prelates. In the days of chivalry, it was the custom for the knights to wear the glove of a lady in their helmet, and this gift from the fair sex was esteemed a great favour, the knight's success in arms being considered as owing to the virtue of the lady. Throwing down the glove, or gauntlet, was likewise esteemed a challenge to single combat amongst our ancestors, and he who took up the glove thus cast our ancestors, and he who took up the glove thus cast down was deemed to have accepted the wager of battle. According to an ancient custom, it is the practice on a maiden assize,—that is, when there is no offender to be tried,—for the sheriff to present the judge with a pair of white gloves; also, during the time fairs were held, it was the custom to hang out a glove from the town-hall, and as long as it

hang out a glove from the town-hall, and as long as it remained suspended there, all persons visiting the fair were privileged or exempt from arrest; and the taking down of the glove was a signal that the fair was closed and the privilege at an end.

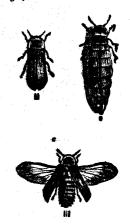

GLOVE MANUFACTURE.—The principal substances of which gloves are made in the prefent day are dogskin, doe, buck, lambskin, kid, and various other kinds of leather; besides silk, cotten, wool, and admixtures of the same. Particular kinds of gloves are known more from the place in which they are manufactured, howfrom the place in which they are manufactured, how-ever, than from the substances of which they are com-posed; as Berlin, Woodstock, Limerick, and Kendal. Kid gloves are the most used, and obtain the highest price in the market; the best of these are of French price in the market; the best of these are of French make, and hardly any of English manufacture can come up to them in point of elasticity and general excellence. Sheepskin gloves are usually of a white colour, and are greatly used in the army. Doeskin gloves are of a soft leather; and Woodstook gloves are a coarser variety of these. The English glovers were a coarser variety of these. The English glovers were incorporated as a "guild" in the reign of Charles II., in the year 1863. The process of glove-making is very simple; and, since the introduction of machinery into the trade, admits of no complicity of manufacture. The dressed skins are first cut out by cutting-machines, and the finger and thumb pieces are likewise separately cut. These disjointed particles of the glove are given into the hands of the sewers, who work it up into the desired form. The sewers use a clasp or clam, which is held between the feet and knees, and clasps the leather

while being sewn. It is stated that, during the years 1856-7-8, French gloves were imported into this country at the rate of 4,000,000 pairs per annum. There is no doubt that the sewing-macfines have considerably lessened the cost of glove-manufacture since they were introduced into England; and although we are not on a par with the French in the average quality of our gloves, yet some of what are termed the "best town-made" are equal to, if they do not surpass, any of the productions of the Paris glovers.

GLOW-WORM, glo'-wurm (Ang.-Sax.). (Lonworis

GLOW-WOLM, glo'-wurm (Ang.-Sax.), (Lompyris noctiluca).— This well-known insect is rather more than half an inch in length, and of a blackish colour.

than half an inch in The thorax is mar-rined with dusky red, the legs and the segments of the body being of the same colour. The female resembles the mule, but is quite destitute of wings. It is not certainly ascercertainly ascertained whether the male glow-worm is capable of emit-ting a phospho-rescent light; and it is generally a-greed, that if the power exists at all, it is in a very slight degree: it is to the female that the name of glow-worm. applies. The light proceeds from the under part of the abdomen, and near the tip; and it appears that the insect has the power to increase or subdue

1. BRITISH GLOW-WORM, FRM. 2. DITTO, MALE. 3. MALE, FLYING.

sect has the power of the intensity of the light at will. Latreille ascertained by experiment that the glow-worm will live a long time without air, and in different kinds of gases. If the luminous part of the body be removed, it will continue for a considerable time to shine; and when the light is apparently extinguished, can be again kindled by softening the matter in v. ier. If immersed in warm water, the insect still preserves its luminosity, but if placed in cold water, the power is suspended. The female being a slow-moving inactive insect, it is supposed by some naturalists that the light emitted by the female acts as a beacon to the opposite sex. The larves have been kept beacon to the opposite sex. The larve have been kept for a considerable period, living upon snails, and killing those of the largest size. "Sometimes they would seize those of the largest size." Sometimes they would seize a snail whilst crawling, and when the animal retired within its shell, they would still keep their hold, and allow themselves to be carried into the shell with the snail; and although they became enveloped in the mucous servetion, it very seldom appeared to adhere to their bodies. Upon being touched or disturbed in any way, the larva emitted the phosphoric light, but not to sogreat a degree as the perfect insect."—English Cyclopadia, art. Lampyride.

GRUUINIUM, glu-sin'e-tum (symbol Gl., eq. 6.9), is metal of comparatively rare cocurrence in nature.

a metal of comparatively rare occurrence in nature, where it is found in combination with silicio acid and where it is found in combination with silicio acid and alumins in the emerald, beryl, and enclase. It is prepared in the same way as aluminum, by decomposing the chloride with potassium or sodium. It is very similar in its properties to aluminium, forming, like it, a seequioxide, glucina, GlpO<sub>3</sub>. Glucina is generally prepared from a mineral called the emerald of Lumoges, which contains silicute of alumina and glucina. It is a white, infusible, insoluble powder, closely resembling alumina, differing from it in forming a carbonate by exposure to the air, and by not forming alums in combination with alkaline sulphases. Its salts have a peculiar sweet taste; hence its name, from glukus, sweet. Its salts have not as yet received any application.

C

Glucoss glu-kose (Gr. glubus, sweet), in Chem, starch, or grope-sugar. A sugar formed from starch, either in the natural organism, or by allowing a mixture of starch and water to flow into a vessel containing a solution of sulphuric acid of one per cent. strength, at a temperature of 130°. The liquid is continually stirred and kept in a state of shullition for half an hour, as soon as all the starch has been added. The liquid is one drawn off and neutralized with chalk, the precipitate allowed to subside, and the clean solution set aside to crystallize. Glucose crystallizes in hard warty concretions, composed of hard transparent cubes. With common salt it forms a compound that crystallizes with facility. It also forms parent cures. When common sair is forms a com-pound that crystallizes with facility. It also forms definite compounds with the alkaline bases, giving rise to a powerful uncrystallisable acid, called gluoic acid. (See also SUGAMS.)

GLUS, glu (Fr. glu). (See GELATINE.)
GLUMACHE, or GLUMIFERE, glu-mai'se-e (from Lat.
gluma), in Bot., a sub-class of the Monocytyledones,
consisting of plants with parallel-veined, permanent
leaves and glumaceous flowers. It includes the Sedges and the Grasses. (SecCYPERACEM and GRAMINADEM.)
GLUMER, glumes (Lat. gluma), in Bot., the outer
bracts of the locusts or spikelet of a grass. (See

BRACT; GRAMINACES.)

BEAGT; GRAMINACEM; GLUTEN, gist-ten (Lat.), in Chem., a characteristic ingredient in cereal seeds. If the flour of wheat or rye be made into appaste with water, and washed in a bag of fine linen, the starch is carried down by the water along with the sugar and destrin: the remainment water along with the sugar and destrin: the remaining grey, sticky, and mucous mass is gluten. It cannot be regarded as a definite body, for, by means of hot alcohol, it may be separated into at least three distinct substances,—one soluble in cold alcohol, which may be precipitated by water in a form resembling albumen, and termed glutin; another deposited by the alcohol as it cools, which has the composition and properties of casein; and a third, which remains undissolved, which may be regarded as vegetable fibrin. Gluten may be assumed to be the principal flesh-forming substance contained in wheat.

Guzgerne, glisterses (Gr. glakus. sweet). in

stance contained in wheat.

GINCHERINE, glis'-er-sen (Gr. glukus, aweet), in Chem. C. M. O., the sweet principle of oils and fats, which is separated from them during the process of saponification; in other words, it is the substance to which stearic, palmitic, oleio, and the other fatty acids, are united in stearin, olein, palmitin, &c. It is a viscid, colourless liquid, of a sweet taste, soluble in water and alcohol in all proportions, but sparingly so in ether. It dissolves most of the deliquescent salts, and many other substances which are soluble so in ether. It dissolves most of the deliquescent salts, and many other substances which are soluble in water. It is slightly volatile at 212°; but if distilled atone, decomposes. It may, however, be distilled numbtered in a current of superheated steam. From its possessing the property of never drying up at ordinary temperatures, it has received many applications in the arts and manufactures. In Med., it is also used in preference to all or other fatty matters. tions in the arts and manufactures. In Med., it is also used in preference to oil or other fatty matters, to keep sores in a soft condition, on account of the case with which it may be washed off. Chemists are somewhat at variance as to its true composition,—one party considering it to be the teratomic alcohol of a base, glyceryl, C<sub>a</sub>H<sub>7</sub>, as vinous alcohol is the alcohol of a base, cthyl:—

in fact, the hydrated oxide of glyceryl. Gerha considers it to be formed on the base glycyl, thus:-Gerhardt

The waxes and spermaceti are not compounds of glycerine. By a very complicated series of actions, Berthelot has been able to form glycerins by synthesis. GLYCHERINE, NITHO. (See NITHO-GLYCHERE). GLYCOCOLL, gli'-ko-seen, gli'-ko-kol, a kind of sugar, obtained from gelatine by the action of sulphuricacid. By transmitting nitrous acid through the aqueous solution, glycocollic acid is formed, which is very similar to lactic acid in its properties. GLYCOL, in Chem., a colourless slightly visoid liquid, with a sweet taste, obtained by distilling binoxide of 947

ethyline, triturated with acetate of silver, and digest-ing the resulting binacetate of glycol with hydrate of potash. The mixture is distilled as soon as the action is complete, and glycol passes over. Its composition ing the resulting binacetate of the school as the school potash. The mirture is distilled as soon as the school potash. The mirture is distilled as soon as the school potash. The mirture is distilled as soon as the school is complete, and glycol passes over. Its composition may be represented by the formula C.H.O., or vinous alcohol, in which the C.H. has a doubly atomic power, being united with four equivalents of oxygen instead of two. It is a very interesting substance to the scientific chemist, the discoveries of Wartz proving it to be the type of an extensive series of derivatives, as numerous as those derived from ordinary alcohol. In a paper read before the Chemical Society of London, he stated it to be the connecting link between the organic and inorganic products of chemistry. An elaborate article on the subject may be found in Miller's "Elements of Chemistry," vol. iii.

GLYCYERHIZA, glis-o-ri'-ad (Gr. glukus, sweet; risa,

on the subject may be found in maniers " macments or Chemistry," vol. iii.

GLYCYRRHIA, glis-e-ri'-zā (Gr. glukus, sweet; riza, root), in Bot., Liquorioe, agen. of Laguminoses, sub-class Papilionaeca. The roots or underground atems of G. glubra, the common or smooth liquorioe, G. echinate, the cohinate-podded liquorioe, and other species, posses a remarkably sweet taste, which is due to the presence of ane nnerystallizable sugar, to which the names of Glycyrrhiein, Glycion, and Liquorice sugar, have been given. The dark-coloured extractive matter which the primares firmish on decoction, contains a large given. The dark-ocloured extractive matter which the rhizomes furnish on decoction, contains a large proportion of this peculiar substance. The extract inspissated is largely imported into this country, under the names of liquorice juice, Brantsh juice, and Italias juice. That imported from Spain is prepared from G. glabra; that from Italy is the produce of G. schwala. About fifty acres of the former plant are under contents at Michele made illuments the profession. nata. About fitty acres of the former plant are under culture at Mitcham, and still more at Pontefract. The annual consumption of liquorice in England is from 1,200 to 1,500 tons. It is used for confectionery purposes and in medicine for flavouring, and as a demulcent pectoral. The great proportion is, however, used by the brewers for colouring porter. Various preparations of liquorice are commonly kept in the shops, and add at the the same of liquorice Postefract. tions of inquorice are commonly kept in the subject, and sold under the names of pipe liquorice, Pontefract lozenges, extract of liquorice, and Solezzi juice. In France there is an extensive use of liquorice-water in the promenades and public places, under the name of coco. It is also sold extensively under the name of the promenaces and punc places, under the name of erguose, in the towns of Turkey and Egypt, like sherbet. Previous to the war, the consumption of liquorice in North America had reached 4,000 to 5,000 tone per annum. The great use of this extract, as a preservative of manufactured tobacco, will partly account for this enormous consumption. The price of liquorice in the United Kingdom has fallen considerably lately, in consequence of the heavy duty formerly paid upon it having been abolished by Mr. Gladstone.

Girphography, gliphy-suffe.— In this process a plate of metal has an ordinary etching-ground placed upon it. The metal is etched in the usual manner. It is afterwards submitted to the action of a voltaic battery, whereby a plate with the drawing in relief is obtained. This plate may be printed in conjunction with type, or separaftely, at a typographical press. The process, which is now very little practised, was intended as a cheap substitute for wood-engraving. Graz, saft (Sax. gnat, Lat. culex), the common type

intended as a cheap substitute for wood-engraving.

Gran, nit (Sax. gnat, Lat. culex), the common type
of the gen. Culicides of Latraille, which is a fam. of
dipterous insects of the section Nemocera. The proboseis is long and slender, projecting forwards, and
terminated by two little lip-like appendages; sucker
composed of six slender bristle-like members; palpi composed of an assence pristie-like members; palpi 5-jointed, generally elengated; antenne filiform, covered with hairs; eyes contiguous, no coelli; wings inclined to the body, and having one marginal and two aubmarginal cells. The common gnat is less than a quarter of an inch in length, and is identical with the length of the control a quarter of an inch in length, and is identical with the insect termed cousis in France and maggatio in America. The pain and irritation which ensure from its sting are caused by the proboscis piercing the skin and a poisonous fluid being injected at the same time. The humming noise which accompanies its flight is caused by the ribration of its wings, which move very rapidly. Granss, rise, in Gool., originally a German term for a peculiar grantite-looking rock, occurring at the very base of the so-called "primary strate;" but now applied not only to the one rock, but to the whole suite of hard crystalline granitoid schists which constitute the lowest portion of the metamorphic strate.

GNETACER, no-tai'-se-e, in Bot., the Jointed Fir fam., a nat. ord. of Dicotylegones, sub-class Gymnospermia.
GNOME, nome (Gr., a sentence or opinion), in Lit. GROME, some (Gr., a sentence or opinion), in Lit., is a short sententious saying, conveying some maxim or moral precept. In the Bible, the Proverbs of Solomon and many of the sayings of Christ afford examples mon and many of the sayings of Christ afford examples of the gnome. The gnomic poets are those Greek poets whose remains consist chiefly of gnomes, short sententious precepts and reflections. The principal writers of this class are Theognis, Solon, Tyrtsens, Simoniers. The best collection of these poets is that of Brunck (Strasburg, 1784; new edition, Leipsic, 1817).

GROME (Gr. paomon, knowing, cunning), is the name given by cabalistic writers to a certain class of name given by cabalistic writers to a certain class of elemental spirits, which they believe to inhabit the earth, and to preside over its treasures. They were of both sexes, and some were said to be beautiful, and others ugly. They sometimes did good, and sometimes evil, to man, the latter especially when they were irritated. The well-known German Rübezahl is a being of this class.

being of this class.

GNONOM, not-mon (Gr. gnomon, the style of a dial), the plate which projects from the face of a dial, the shadow of which shows the time of day according to the aun, as it moves along the graduated edge of the dial-plate. In constructing a sundial, the plate is placed either in a vertical or horizontal position (see SUNDIAL), and the gnomon must be in the plane passing through the meridian of the place, having its cloping edge parallel to the axis of the earth, and forming an angle with the horizon equal to the latitude of the place.—In Math., this name is given to the of the place.—In Math., this name is given to the figure formed by either of the parallelograms about the diameter of a parallelogram, and the complements or subsidiary parallelograms, that make up the entire figure when it has been divided into four parts, by two lines drawn parallel to its sides, and transversely to each other, through any point in the diameter.

cano oner, through any point in the diameter.

Grownon's Projection, no-non's it, the name given
to the method of projecting the whole or a part of a
sphere on a plane surface, which is based on the method
adopted in the construction of a sundial. The eye is
in this case supposed to be in the centre of the sphere,
and all its creat given are consequently received or and all its great circles are consequently projected on any plane surface, beyond that of the sphere in straight lines, a property which is entirely confined to this hand of projection. Sir John Lubbock's Maps of the

Aind of projection. Sir John Lubbock's Maps of the Stars, originally published by the Society for the Diffusion of Useful Knowledge, and now by Stanford, are drawn in this manner; the sphere of the heavens being supposed to be inclosed within a dibe, on each side of which a sixth part of the sphere is projected by straight lines drawn through the centre.

GROSTICS, nos'-tiks (Gr. gnosis, knowledge), in Eccl. Hist., is the name given to various sects in the early history of the Church, who sought to incorporate the teachings of heathen philosophers with the system of Christianity. Their doctrines were very various, so that it is difficult to give any general account of their principles. According to some, they derived their doctrines from the Alexandrian philosophers; according to others, from the Jews or from the Orientals. There can be little doubt that each of these sources contrican be little doubt that each of these sources contributed to build up the fabric of Gnosticism, some sects taking from one, and others from another, and some, perhaps, from all the three. The apostle Paul, even during his ministry, complains of attempts being made during his ministry, complains of attempts being made to ingraft Jewish and heathen customs and opinions upon the Christian faith; and hence Gnosticism is frequently traced back to this early period. There can be no doubt that the sect became very powerful in the Church soon after that time; and their opinions exercised a great influence upon Christian theology. One of their leading principles seems to have arisen from their in hills to account for the arisence of early in of their leading principles seems to have arisen from their inability to account for the existence of evil in the world. They could not see how God, as all-wise, powerful, and good, could allow evil to exist at all; and they were led to conclude that matter must contain within itself the principle of evil. Hence they came to the conclusion that God had nothing to do with the creation or sustenance of the world, but that he created two beings, called Econs, or emanations, from which sprang other scons, and others from these, an innumerable host, the lower descent being always less perfect than those above them. One of these 523

seons was Demiurgus, who created this world, and was the God of the Old Testament. To counteract the evil that existed, God sent Christ, one of the highest the God of the Old Testament. To counteract the will that existed, God sent Christ, one of the highest sons, into the world, to restore man to the knowledge of himself. They had very inferior notions of the character of Christ, and denied that he suffered death, or that he really underwent the sufferings recorded of him. They did not believe in the resurrection of the body, deeming it too gross for a higher deatiny. Their beliefs influenced their lives in two very different ways, leading some to mortify the flesh, in order to bring themselves into closer communion with God, and leading others to give way to every sinful lust and passion, in order to show their total disregard of the body. In process of time they split into various divisions, differing widely from each other both in faith and practice. Among the principal Choostic sects may be mentioned the Nicolaitanes, Saturaines, Cerinthians, Basilidians, Valentinians, Ophites, Carporatians, Antitactes, Docets, Marcionites, Tationists, and Bardesanists. The system of Gnosticism disappears about the 5th century.—Ref. Mosheim's and Neander's Church Histories; Möhler, Versuch über den Ursprung der Gnostiken, 1831: Baur, Die Christichen Gnosis in geschichtliche Entwickelung; Gieseler's Ecclesiastical History.

GNU, nu.—This snimal is an equise antelope, belonging to the section denominated Connochetes. It has a broad a pread an pread an pread an expansion was a support of the property and pread appread app

ing to the section denominated Connochetes. It has broad, spreading muzzle; horns lent downwards and outwards, broad at the base, and tapering to a point; the tail long and busby, like that of a horse; the frontal bone much depressed, and the intermaxillary bones elongated. The guu, or kokoon, as it is va-riously termed, inhabits the plains and wilds of South Africs, where it roams about in extensive herds. In Africs, where it roams about in extensive herds. In appearance it is very singular, and at a distance resembles a full-grown ass. The neck, body, and teil, as well as the pace of the gnu, are nearly identical with that of a donkey or small horse, while its horns, and the long hair which surrounds its face and muzzle, give it the most uncouth appearance imaginable. The gnus are extremely wild and difficult for the hunter to approach, and from their firmness and courage a good deal of danger is attendant in shooting them. In height they are generally about three feet and a half at the shoulder, and their colour is a dark brown. The horns are common to the female as well as the male. When they are surprised by the hunter, in the first alarm they commence flighing up their heels, and start about like a frightened horse; but they immediately afterwards take to flight, and career over immediately afterwards take to flight, and career over the plains at a speed which soon out-distances the hunter, who must trust more to take them by strats-gem than by hoping to run them down. When they nunter, who must trust more to sake them down. When they are wounded, they will often turn on their assailant, and attack him with the greatest fury, often besieging him in some mound or tree for days. Before attacking, they first drop on their knees, and then spring upon their foe with immense impetus. It is said that the guu is subject to a sort of eruption on the skin or the gu is subject to a sort or eruption on the sun or other cutaneous disorder, which attacks the different herds at a particular season of the year; and that if domestic cattle become infected with it, it is certain to end in their death. When taken young, the gun is very easily domesticated, and is often adapted to the plough in South Africa.

plough in South Africa.

Goar, gote (Sax. gar).—The domestic gost, according to Cuvier, varies more in size, stature, length and fineness of the hair, than any other animal, with the solitary exception of the dog. Its distinguishing characteristics, from the Linnean system of zoology, are as follows: The horns are hollow, turned upwards, annulated on their surfaces, and knotted in front. There are eight cutting teeth in the lower jaw and none in the upper; and the male is generally supplied with a beard or tutt of hair under the lower jaw. The original stock from which this animal sprung has been discovered by the researches of modern students of original stock from which this animal sprung has been discovered by the researches of modern students of natural history to have been the Ægagrus, or wild gost, which inhabits the mountains of Caucaus and Persia. The domestic gost is one of the most useful of animals to man, and it bears every temperature, from that of the tropics to as far north as Wardhuys, in Norway, where it remains exposed to all the inclemencies of the weather all day, being only sheltered at

night in hovels which are nearly as much exposed as the open fields. In Norway, it feeds on moss and the bark of the fir-tree. The milk of the gost is far richer than that of a cow, and the hair is particularly useful in manufacture. The skin, especially that of the kid, is used for the making of gloves, and the flesh is often eaten, although it is rather coarse,—that of the kid is esteemed quite a delicacy. The condition of the goat in the British islands is much more wild than that of any other of our domestic animals: from its being a courageous and powerful animal, its temper and motions are particularly inconstant, and it roams over motions are particularly inconstant, and it roams over the mountains of Wales as if it had never been domesthe mountains of Wales as if it had never been domes-tioated, although, at the sight of the herdsman, it will be far more quick and playful and show more affection than the sheep, to which it is undoubtedly superior in many instances. The Cashmere goat is smaller than the domestic goat, and is likewise valued for the fine-ness of its Sacce. the domestic goat, and is likewise valued for the fineness of its fleece. This variety is a branch of the Thibet goats, which pasture on the Himalays Mountains, in Hindostan. Both these species have a long outward hairy covering, and beneath this is a fine and beautiful coat of wool. From this wool are made the magnificent shawls which form such an important item in the Asiatic trade. Many attempts have been made to cross the breed of the goat with the sheep, and some very successful results have followed. The Cashmere goat having been bred in with the Merino, a mule has been the result, which partakes of the good qualities of both. The Rocky Mountain goat of North qualities of both. The Rocky Mountain goat of North America is another variety, and ranks next to the Cashmere goat for the excellence of its fleece. (See also ANGORA GOAT.)

GOAT-MOTH (Cossus ligniperda) belongs to the section Lepidoptera nocturna moths, and its family Hepi-It is the largest of European moths, the expansion of its fore wings sometimes exceeding three inches. The colour of the hind wings is brown, with darker variations or mottles throughout the surface; while the fore wings are a dusky white clouded with brown, and varied with black irregular streaks, formbrown, and varied with black irregular streaks, forming a species of network. The thorax is a buff-colour, and the body is of a dark brownish-grey colour, with silver rings round it. The larva is about three inches in length when full grown, and takes three years to arrive at maturity, during which time it incloses itself in a tough occoon, formed of pieces of wood gummed together with a glutinous sort of gum. The larva or caterpillar lives on the wood of the poplar, oak, and aspen, which it perforates in large holes; whence its name of Lightperds.

GOAT-BUKKE. OF NIGHELAR (Caprimulans surrongus)

GOAT-SUCKER, or NIGHT-JAR (Caprimulgus europ is a bird which derived its name from an absurd idea or supposition, that it was in the habit of sucking the or supposition, that it was in the habit of sucking the teats of goats and other animals at night. These birds form the tribe of \*\*Fisirostres nocturns\* of some naturalists, and are closely silied to the swallows and swifts, from which, however, they may be readily distinguished by the largeness of their eye and the softness of their plumage,—characteristics which are common to the generality of night-birds. The bill is short and depressed, and is very broad, with an enormously wide gape, which extends beneath the eyes, and is bounded by long bristles; the tarsi are short, and the toes long and strong: the wings are long and pointed. The goatsuckers are found in all parts of the world, and their habits are nearly identical. They fly about at dusk, in pursuit of moths and beeties; and from the rapidity and elegance of their flight, they are frequently mistaken for swallows. Their colour is plain, but beautifully variegated by being freckled and barred with black, brown, and grey feathers diversely arranged. There are numerous varieties of this bird; as the banded goat-sucker and the crested goat-sucker; but they are all very closely alike. (See Whire-Pools-Will.) of goats and other animals at night. WILL.)

WILL.)
GOBELIN TAPERTRY. (See TAPESTRY.)
GOD (Ger. Gott, Fr. Dieu, Lat. Deus, Gr. Theos) is the name given to the Creator and Sustainer of the universe, the High and Holy One, who is the object of human worship. The term is of Baxon origin, being a contraction of good. The belief in the existence of some being or beings superior to man, on whom he is dependent, and who demands his worship, is so universal that is may almost \$\mathbb{\end{a}}\$ said to be an instinct of

Gog and Magog

our nature. Those who worship many gods are termed polytheists; those who worship one only, monotheists. The department of knowledge which treats of the being, perfections, and government of God, is called theology. Many attempts have been made, by arguments, to prove the existence of one Supreme Being, all-powerful, wise, and good, through whom everything exists. Some of these arguments are a priori, others are d posteriori. "When we argue from the ideas we have of immensity, eternity, necessary existence, and the like, that such perfections can reside but in one Being, and thence conclude that there can be but one Supreme God, who is the cause and author of all things,"—this is an argument a priori. When, on the other hand, like Dr. Paley, we argue from the order and regularity that we observe in the objects of nature around us, that there is evidence of design and of a designer, this is an argument a porterior. Each of these modes of argument, however, is incomplete of itself, and it is only by a combination of the two that we can expect to be able, if, indeed, the imperfection of our present faculties will ever admit of our being able, to prove by arguments the existence and attributes of God. At least we have not been left to such resources, seeing that He has seen meet to give us a revelation of Himself.

Godarners and Godnothers, god'-fu-thers, god'-muth-erz (Ang.-Sax.), the names given to the male and female sponsors of a child at baptism. According to the principles of the Church of England, for every male child two godmothers and one goddsther. Each sponsor must be a baptized person, of full age, acquainted with the Lord's Prayer, Creed, and Ten Commandments, and acquainted with the fundamental truths of Christianity. It was especially enjoined upon sponsors that they should see to the children being instructed in the principles of Christianity. and take care, by admonition and

acquainted with the fundamental truths of Christianity. It was especially enjoined upon aponsors that they should see to the children being instructed in the principles of Christianity, and take care, by admonition and instruction, to enforce upon them the importance of their performing their part of the contract. Practically, however, it has become little more than a mere form, the godfathers and godmothers usually giving little or no heed to the future training of the child. The origin of this institution is very ancient, but the period of its rise is not exactly known. No trace of it occurs in the New Testament, but it was practised in the 2nd century, and was in general use trace of it occurs in the New Testament, but it was practised in the 2nd century, and was in general use in the 4th and 5th. It probably arose from the Church requising replies to the interrogatives put at baptism; and hence, in the case of infants, the necessity of there having some one to answer for them. In the Roman Catholic Church a sort of spiritual relationship is regarded as established by this connection, constituting by the aron law an impediment to martionship is regarded as established by this connection, constituting by the canon law an impediment to marriage between the sponsors and the baptized or the parents of the baptized. In the Presbyterian and other non-episcopal churches the parents stand in the place of sponsors, the father taking upon himself the haptismal vows as to the religious up-bringing of the child.

child.
GOD'S TRUCE (Ger. Gottesfriede, Lat. Trenga Dei, or Treva Dei) is the name of an institution of the middle ages; a means introduced by the Church to check in some measure the hostile spirit of the times, by establishing certain days or periods during which all private feuds were to cesse. It seems to have taken its rise about the latter part of the 10th or beginning of the 11th century. At first the Church forbade all feuds on those days of the week which were specially consecrated by the death and resurrection of Christ; namely, from Thursday evening to Monday morning, and threatened with excommunication any who transgressed that order. Afterwards the period was extended so as to include the whole of Thursday, the whole of the period from the beginning of Advent to iended so as to include the whole of Thursday, the whole of the period from the beginning of Advent to the Epiphany, and certain other times and saints' days. The precincts of churches, convents, and graveyards, were also interdicted from any hostile encounters. Though frequently disregarded, there can be little doubt that these enactments were of much use in these troublous times. By degrees the power of the State came to be scretch to promote peace, and these laws of the Church gradually fell into disuse.

Gog and Magog are two names that occur several

times in the sacred Scriptures. In Gen. x. 2, Magog is mentioned as one of the sons of Japheth; in Ezek, xxviii. xxrix, the prophet is told to set his face "against Gog, the hand of Magog, the chief prince of Meshech and Jubal, and prophesy against him;" and in Rev. xx. 8, Satan is represented as going forth "to deceive the nations, which are in the four quarters of the earth, Gog and Magog to gather them together to battle." Among Christians, the terms have been used as nearly synenymous with Antichrist, and in a general sense to include all nations hostile to Christianity. These names are also employed to Christianity. These names are also employed to designate two huge warlike figures, that adorn the Guildhall of London. Many fables are given of the origin of these worthies; but nothing with certainty is known regarding them, further than that from time immemorial they have been locked upon with pride by the people of London. The old giants, which were of times in the sacred Scriptures. In Gen. x. 2, Mathe people of London. The old giants, which were of wickerwork and pasteboard, were destroyed by the great fire of 1666, and the present ones, which are of stone, were constructed in 1708. They are fourteen feet high.

high.

ORTER, goy-tr (Fr. goitre, probably a corruption of Lat. guttur, the throat), is a preternatural enlargement of the thyroid gland, occasioning a swelling of the throat, which frequently attains a very large size. It is also termed Bronehocele (Gr. bronehoe, the throat, and kele, a swelling), and Derbyshire neck, on account of its prevalence in the hilly parts of Derbyshire. It is, however, in the Alpine districts of Europe, especially Switzerland, Savoy, and Tyrol, that it is chiefly to be met with. It is also common in certain regions of the Andes and Himalayas. It is frequently associated with oretinism (which see). Little is yet known of the nature or cause of this disease. It is endemic, or common to certain regions; but from what peculiarity or common to certain regions; but from what peculiarity of these regions it is owing is very uncertain, though many are inclined to attribute it to a calcareous impregnation of the water. It also occurs hereditarily, independent of endemic influence. It is much more common among females than males, and usually occurs about the age of puberty. It is not of an inflammatory or malignant character, is free from pain, and generally of the natural colour of the skin. At first the tumour is soft and elastic : but as it increases in size, it becomes hard and firm. Its size often becomes so great as not only to be a serious inconvenience, but even to impede respiration and obstruct the voice. The great remedy for this disease is iodine, either administered internally in small doses for a long time, or applied externally, either in the form of an cintment, or of the tineture

either in the form of an cintment, or of the tincture painted over it every night. Generally, if not of long standing, the swelling will in this way be removed. GOIDRESTICES. (See SARGASSUM.) GOID, gold (Sar. gold), symbol An. (aurum); equiv. 197; spec. grav. 193. Pure gold for chemi-cal purposes may be obtsined by dissolving standard gold in one part of nitric and four parts of hydrochloric acid. The solution is diluted and filtered, and evapo-rated almost to drypess. to expel the excess of acid rated almost to dryness, to expel the excess of acid. The remaining salt is then boiled with a solution of The remaining salt is then boiled with a solution of sulphate of iron, which precipitates the gold as a dark bluish-purple powder, which is subsequently washed with water and hydrochloric acid. Gold, in its ordinary metallic form, has a reddish-yellow colour, but when very much extended, it transmits a green light, being purple by reflected light. When pure it is nearly as soft as lead, and is the most malleable and ductile of all metals, but is inferior to many in its tenacity. It does not combine directly with any of the non-metallic alements, except chlorine, bromine. tenacty. It noes not combine unreally with any of the non-metallic elements, except chlorine, bromine, fluorine, and phosphorus. The oxygen acids do not combine with either of its oxides, and the only way in which the chloride can be formed is by dissolving it in which the chloride can be formed is by dissolving it in hydrochloric acid, to which some cxydizing substance has been added, such as nitric acid, chromic acid, or binoxide of manganese. Selenic acid acts upon it by oxidation, its acid being converted into scienious. The hydrated alkalies do not act upon gold, except in a strong current of air, when auric acid is formed, which combines with the sikali. The higher alkaline sul-phides dissolve it in the form of tersulphide. Gold, in Metall.—This important metal occurs in con-siderable apartite; in different parts of the world, more siderable apartite; in different parts of the world, more

siderable quantity in different parts of the world, more especially in Mexico, Peru, Brazil, the Ural Moun-

Gold, Chlorides of

tains, California, Australia, New Zealand, and latterly
in British Columbia and Vanouver's Ialand. It also
occurs somewhat aringly in the rivers of Hungary,
Wicklow, and Walse. As the larger portion of the
gold used by mankind is found in the British possessions, it will be necessary to consider its metallurgy
somewhat fully. Gold is always found in the metallic
state, generally alloyed with silver or tellurium; its
extraction from the ore is therefore a simple matter.
When the metal is disseminated through quartz
pyrites or lead, the ore is pounded, and washed with
a stream of water, which carries away the lighter
portions of sand, leaving the heavy metal behind. It
is further freed from impurities by being amalgamated
with quicksilver, which is afterwards distilled off. In
this state it generally contains from 2 to 10 per cent.
of silver or tellurium. It is further reflued by being
finely granulated and boiled with concentrated sulphuric acid until every other constituent is dissolved
out. Perfectly pure gold—24-carat, or fine gold, as it
is termed—is too soft to be used as ornaments, coins,
vessels, &c.; it is therefore alloyed with one part of
copper to eleven of gold for coning purposes. This is
called standard or 22-carat gold. Jewellery is generally made of 18-carat gold, which contains one quarter
of copper. Gold, by being alloyed, loses much of its
ductility and malleability, but gains in fusibility and
hardness. To gild glass or porcelain, gold-leaf is
made into a paste with turpersine and oil, and laid
on with a brush, which is afterwards heated in a
mullle and burnished. Wood, plaster, and papier mdché are covered with geld-leaf by the intervention of
size or varnish. Metals are gilt either by the use of
gold amalgam, by immersion in a solution of gold, or
by the electrotype process. In gilding by amalgametion, the articles to be gilt are made perfectly chan,
and rubbed over with a brush dipped in nitrate of
mercury and the amalgam: they are then heated to
expel the mer and rubbed over with a brush dipped in intrate of mercury and the amalgam: they are then heated to expel the mercury. Copper articles are often git by immersing them in a solution of an alkaline aurate. Electro-gilding is described under that head. Gold alloys are assayed in two ways, -by rubbing the article on a touchstone so as to make a metallic streak, which is touched with aqua regia, and the effect is compared with that of a similar streak made by an alloy of known composition. By this means an experienced operator composition. By this means an experienced operator can estimate the amount of alloy in any mixture correctly within one per cent. When great exactitude is required, the process of cupellation is resorted to. A mixture of one part of the alloy to be assayed is made with three or four parts of silver and three or four of lead, which is fased upon a bone-ash cupel. The lead carries down the whole of the impurities, excent the silver into the cupel leaving nothing but the except the silver, into the cupel, leaving nothing but the gold, alloyed with three or four times its weight of silver. It is then beaten out and immersed in nitric acid, which dissolves out the silver, leaving the gold pure. The amount of silver used must be at least three times that of the gold, otherwise the silver diffused through the mass would be protected from the action of the nitric acid by the nobler metal. The first of these processes, where the gold is alloyed with the silver, is known as quartation; and the separation of the metals by nitric acid is termed parting. As gold is diffused through nearly all our colonies, as short method of testing for its presence will be useful. The minerals most usually mistaken for it are copper and iron pyrites, which may be easily recognized by their giving off sulphur when roasted on a metallic plate. off sulphur when roasted on a metalic plate. They may, however, contain gold; in which case they should be roasted, powdered, and dissolved in aqua regia with the aid of heat. The solution should be carefully neutralized with carbonate of soda, filtered; and a solution of protosulphate of iron should be added as long as there is a precipitate. The precipitate is fil-tered and washed in nitric acid, and the remaining insoluble matter is the amount of gold contained in the mineral. This may be further confirmed by disthe mineral. This may be further confirmed by dis-solving it in hot aqua regir, neutralizing, and adding a solution of protochloride and perchloride of tin. Or if the gold is generally diffused through the mass of a mineral, it should be powdered fluely and shaken up with a quentity of mercury, which, when poured off and distilled, leaves the gold behind.

Gold, Chichies of, in Chem.—With chlorine,

Gold, Cyanide of gold forms two salts,—the protochloride, AuCl, formed as a pale yellow insoluble substance, when the terchloride is heated to 392° Fahr.; and the terchloride, AuCl, which is made by dissolving metallic gold in aqua regia. The latter salt is very soluble in water and alcohol, forming a yellow or orange solution, according to its strength. It has an acid reaction, and stains the skin purple. Ether dissolves it still more readily, abstracting it from its aqueous solution when mixed with it, and forming a yellow layer on the surface. The thereal solution is the aurum potabile of the ancients. Terchloride of gold is easily reduced by the feeblest deoxidizing agents; its solution should therefore be kept in a dark place. It is greatly used as a toning agent in photography, and cocasionally in medicine. It is capable of forming very distinct double salts with the sikaline chlorides, which are much more stable than the chloride itself. The auro-chlorides of potassium and sodium are much used in chlorides of potassium and sodium are much used in

chlorides of potassium and sodium are much used in photography. Digested with a solution of ammonia, it forms tulminating gold. It is formed by dissolving pure gold in aqua regia, and carefully crystallzing.

GOLD, CYANIDE OF, AND POTASSIUM, in Chem.

The protocyanide is the only cyanide of gold known. It is easily formed by adding a solution of cyanide of potassium to a weak solution of terchloride of gold. It is a lemon-yallow powder, readily soluble in excess of cyanide of potassium, forming the double cyanide of gold and potassium, which is largely used for gilding by the electrotype process.

GOLD LACK. a beautiful ornamental fabric, produced

for gilding by the electrotype process.

Gold Lace, a beautiful ornamental fabric, produced by applying a thin coating of gold to threads of silk. In the original method, a stiff thread was produced, long used for making cloth of gold, &c.; but manufacturers have been enabled to apply gold to flexible thread, by means of recent inventions. The first prothread, by means of recent inventions. The first pro-cess is sometimes called fibre-plating, and has been long known to Eastern and European nations. The mode of making Euglish gold lace in its commence-ment is similar to that adopted by the Hindoos. A bar of silver is roughened and coated with a film of gold; the rod is then drawn out into a wire, and finally twisted round orange-coloured silk thread. For the finer kinds of wire thus made, perforated rubies are used as kinds of wire thus made, perforated rubies are used as dies, and an ounce of metal can be brought to the astonishing length of a mile and a quarter. A piece of this wire, twelve inches long, and finer than a human hair, will sustain a weight of twelve ounces. The pro-cess of costing flexible threads with gold film is called the militial Chamista and manufactures have long cess of coating itextile threads with gold film is called fibre-gilding. Chemists and manufacturers have long tried to overcome the many difficulties which stand in the way of fibre-gilding. Many processes have been tried both by chemical and metallurgical processes; but although it was found easy to attach the gold to the thread, yet the whole was too long in drying, and had too soft a foundation, to admit of burnishing. The brilliancy of gold lace produced by fibre-plating has never been surpassed or even imitated by any of the processes invented. Among the principal methods in never been surpassed or even imitated by any of the processes invented. Among the principal methods in use are the chemical processes of Mr. Albert Hook and Mr. Green, patented in 1853, and that of Dr. Kroning of Stolberg. Electro-metallurgy has not been rendered directly applicable; but by M. Barot's method, the material to be gilt is dipped in a solution of nitrate of silver and ammonia. After remaining two hours, and dried, it is exposed to a current of pure hydrogen gas. A silvered surface is thus produced, which can easily be gilt by the electro-metallurgic process. Grow Mosato.—This term is generally applied to the bisulphide of tin, which has a metallic instre and colour resembling the precious metal. It is also popularly used to denote an alloy of copper and sinc or tin

larly used to denote an alloy of copper and zinc or tin

imitative of gold.

imitative of gold.

GOLD, OXIDES OF, in Chem.—Gold forms two oxides. The protoxide, AuO, is a violet-coloured powder, obtained when a dilute solution of potassa, is mixed with the protochloride: it dissolves in alkalies by forming metallic gold and auric acid, which combines with the alkali. Although it does not combine directly with the oxygen acids, it forms a peculiar compound with hyposulphite of soda, much used in photography under the name of sel d'or. It is regarded as a union of hyposulphite of protoxide of gold with three equivalents of hyposulphite of gold and tin. combines with the alkali. Although it does not combine directly with the oxygen ands, it forms a peculiar but thin membranes are placed between it and the compound with hyposulphite of soda, much used in photography under the name of sel d'or. It is last and finest set consists of goldbeater's aking gold with three equivalents of hyposulphite of protoxide of another set of very smooth and fine calf-skin vallum, gold with three equivalents of hyposulphite of soda. In the same manner it forms a stanuate of gold and tin, riband of gold is first out up into small pieces, each and

much used to impart a purple-red colour to glass and porcelain, under the name of purple of Cassius. Both the compounds named above have been the subject of much discussion; the formule indicated represent the newest theories with regard to their composition. Teroxide of gold, or curic acid, AuO, is a powder of a yellow or brownish colour; it is easily reduced to the notatile tests the avenue as in light. is a powder of a yellow of prowain colour: it is easily reduced to the metallic state by exposure to light. It is insoluble in water, but dissolves readily in nitric, sulphuric, and scetic acids, without forming salts, the oxide being reprecipitated on adding water. It is pre-cipitated by decomposing a solution of terchloride of cold with progressis. The mixture formats of manuals cipitated by decomposing a solution of terchloride of gold with maguesis, the mixture of sursts of maguesis and magnesis formed is boiled with nitric acid, which dissolves the magnesis, leaving hydrated suric acid behind. Under the action of the hydracids it is resolved into the tersalt of the halogen. It forms salts with potash and sods, by dissolving it in the alkali and evaporating in vacuo. There are also said to be two other oxides of gold, AuO, and AuO,, but their properties require investigation. properties require investigation.

two other oxides of gold, AnO, and AnO, but their properties require investigation.

Gond, Sulfitures of, in Chem.—There are two sulphides of gold,—the protosulphide and the tersulphide, corresponding to the oxidez and chlorides; but little is known of their properties.

Goldbeaters are strike a delicate membranous substance used by goldbeaters, and obtained from the large intestine of the ox. This intestine consists of three coats or sheathings,—the intestine consists of three coats or sheathings,—the intestine consists of three coats or sheathings,—the intestine of the ox. This intestine consists of three coats or sheathings,—the intestine of the ox. This intestine consists of the existing of the peritoneal membrane is the one used in making goldbeater's skin. After the intestine has been freed from all greasiness by washing, scraping, &c., it is turned outside in, and allowed to steep for some hours in a tub containing strong alkaline fluor; the peritoneal membrane is afterwards removed, stretched, and dried. In fluishing the process, individual manufacturers have their own processes. A packet of skins properly prepared is costly, but it will bear a great amount of beating without injury. Skins may be used for several months without becoming thinner or weaker. A mould or group of goldbeater's skin, containing about 800 pieces, is valued at £10.

Goldbeatering, the art of reducing gold to the state of pieces, is valued at £10.

or group of goldbeater's skin, containing about 800 s pieces, is valued at £10.

GOLDBEATING, the art of reducing gold to the state of very this leaves, for use in various methods of gilding. On account of the extreme malleability of gold, this art has been practised from very remote times; it is spoken of by Homer, and Pliny states that one ounce for gold was beaten out into 750 leaves, each leaf being four fingers square, or about three times the thickness of the ordinary modern gold-leaf. The ancient Perutivians made very thin sheets of gold; and the art seems to have been practised in India, to judge from the rude is specimens of gilding found at Bangalore, in Tippoo Saib's palace. At the present day, according to experiments which have been made, it has been ascertained that one grain of gold can be beaten out so as to cover 75 square inches; and taking one cubic inch of gold at 4,900 grains, it will be found that the gold-leaf was the \$367,650th part of an inch in thickness, or 1,200 times thinner than ordinary printing paper. The manufacture of gold-leaf is a combined process of rolling and hammering. The gold, which is variously alloyed, according to the colour required, is melted in a small crucible by the heat of a wind-furnace; it is then cast into a mould, so as to form a flat oblong bar about three-quartary of an inch wide and two ounces then cast into a mould, so as to form a flat oblong bar about three-quarters of an inch wide and two ounces in weight. After being annealed, cleaned, and cooled, the bar is transferred to the mill, where, by means of two rollers of polished steel, the gold is so far reduced two rollers of polished steel, the gold is so far reduced that the two ounces are spread out over a surface of 960 square inches, with a thickness of rather more than  $\kappa_{n}^{+}$  th of an inch. Before the introduction of the mil, this part of the grocess was performed with a forging-hammer, and in France the same method is still adopted. After being reduced to the proper thickness, the riband of metal is transferred to the goldbeater. The hammering does not take place on the gold itself.

inch square, and 150 of these are interleaved with an inch square, and 150 of these are interleaved with an equal number of leaves of vellum, about four inches square, each piece of gold being placed in the middle of a sheet. A parchment case, open at both ends, is then drawn over this packet of vellum-leaves, and over this another parchment case, at right angles to the first. The beating then takes place upon a smooth block of marble, strongly embedded beneath, and inclosed with woodwork on every side but the front which is furmarble, strongly embedded beneath, and inclosed with woodwork on every side but the front, which is furnished with a leathern apron to preserve any fragments of gold that may fall out of the packet. Very ponderous hammers, weighing 18, 13, and 10 lbs. respectively, are employed: the heaviest is used at first, and the lighter ones as the gold is beaten thinner. The beating is continued until the one-inch square pieces of gold are expanded to nearly the size of the vellum-leaves; each sheet of gold-leaf is then out into four equal parts, and the 600 pieces so obtained are transferred from the vellum coverings to layers of goldbeater's skin. The whole is inclosed in parchment, and the beating continued with a lighter hammer until goldbeater's skin. The whole is inclosed in parchment, and the beating continued with a lighter hammer until the gold nearly attains the size of the skin-leaves: at this point each sheet of gold-leaf is again cut into four pieces; the 2,400 being too many to be beater in one packet, are divided into three parts, and beaten separately: by three beatings and two quarterings the gold-leaf attains the necessary degree of thinness required. One hundred square feet of gold-leaf thus produced only weigh one cause. weigh one ounce.

weign one ounce.

GOLDEN AGE, gold'-en aij, a time set down in the mytholigies of nearly all countries as having existed at some very remote period of antiquity, when the earth was the common property of all, and produced everything necessary to man without cultivation; when good prevailed and evil was unknown; when the lion laid down with the lamb, the land flowed with milk and honey, and peace reigned supreme. The Greeks and honey, and peace reigned supreme. The Greeks and Romans believed that the earth became gradually de-generated from its first establishment, and that three generated from its first establishment, and that three ages, of gold, of silver, and of iron, were to exist successively, and had existed each in their turn, until the last, at the end of which all things would be changed, and the golden age once more resume its interrupted sway. There seems to be some analogy between this belief and the dream of Nebuchadnezzar in the book of Daniel, and there is no doubt that the idea has been inculcated in the mind of man, in order that he should look forward to a brighter and better state of existence.

GOLDEN BULL. (See BULL, GOLDEN.)

GOLDEN LEGEND (Lat. Aurea Legenda), a work of a Dominican friar, James de Vorsigne, who was born in or about the year 1230, and who became first provincial of his order, and afterwards archibishop of Genos. The Golden Legend consists of a history and description of all the different saints and festivals in the calendar. From the fact of its being more descriptive than critical, it illustrates the religious habits. tive than critical, it illustrates the religious habits of the period better than any other work could have done, and its tenor is rather to inculcate good by example than to convince by metaphysical or philosophical

than to convince by metaphysical or philosophical argument.

GOLDEN NUMBER.—This number, sometimes called the Prime, is that by which any year is numbered in the particular cycle of nineteen years in which it is included. It is said to be so called because it was distinguished in almanaes of former days by being put therein in letters of gold. It is used in determining the day of the year on which Easter falls. (See Easter, Merowice Cycle.) To find the golden number for the

brown, and rump a pale brown, the belly white, and a beautiful yellow stripe runs across the wings, which are principally black, with white edges. Altogether, it is the handsomest bird we have, and as its song is very sweet, the goldfinch is a universal favourite. It feeds on the seeds of various plants, particularly that of the thistle. It is found throughout Europe, but principally in the United Kingdom of England and Ireland. Buffor are of it "that beaute of numera making." Buffon says of it, "that beauty of plumage, melody of Bullon says of it, "that beauty of plumage, melody of song, and sagacity of disposition, are all united in the goldfinch," and if it were not a native bird, it would be much higher prized than it is. Being of very lively habits, the goldfinch can be easily trained both to imitate other birds, and thus be of use as decoy, and to perform all manner of funny tricks for the diversion of its master. "There is a company of goldfinches, linnets, and canaries now exhibiting in London, which

GOLDFINCH.

perform a number of parts and different characters. One appears to be dead, and allows itself to be held up by the tail or leg, without showing any signs of life; another stands on its head, with its claws in the air; a third carries a couple of milk-pails, as if it had been bred up to the occupation; whilst a fourth bears a rifle, and fulfils all the duties of a sentry on guard. Another discharges s little cannon, which it attends to in the capacity of an artilleryman; while yet another in the capacity of an artilleryman; while yet another draws a little carriage along with the greatest facility, in which two of its comrades are seated with the utmost sang-froid." Many anecdotes could be related, if space permitted, of the numerous tricks which these clever little birds are able to perform. The reader is referred to Yarrell's British Birds. (See also FRIM-CILLIDA: )

reterred to larrei's British Birss. (See also FRIN-CILLIDE).

GOLD-RISH (Cyprisus awratus) belongs to the general class Cyprisude, and the section Malacopterygii abdominales, a species of fish distinguished by having the mouth small, formed by the intermaxillary bones, and devoid of teeth, the branchiostegous rays few, and the scales generally of large size. The gold and silver fish, as the gold carp is termed, has been long known in England; it was introduced into this country in the year 1691, from China, of which land it is a native. It is called the gold-fish from the splendid brilliant colour of the membrane which lies immediately beneath the scales. It is completely naturalized in Europe; in Portugal, in fact, it breeds freely in the open rivers. The colours of this fish are very various, some being all gold-colour, whilst others are of a fine bluish-brown or silver hue. When young it is very dark, nearly of a black colour. Sometimes the fins are doubled in the gold-fish, and they often have triple tails. It is not eaten, but valued from the beauty of its appearance. the day of the year on which Easter falls. (See EASTER, MEZONIC CYCLE.) To find the golden number for the year carrent, add I to the date of the year and then divide by 19—the remainder will be the golden number for the year; but if there be no remainder, then 19 will be the golden number. Thus the golden number for the year; but if there be no remainder, then 19 will the the year 1864 is 3, the number which happens to be the golden number. Thus the golden number for the year; leaf adding 1 to the date of the year and dividing the sum by 19.

GOLDTHECK, gold-finish (Sax. gold-fine), (Carduelis selegans), a species of bird included in the general class of Fringillidae, and the gayest in appearance class of Fringillidae, and the gayest in appearance of all our native British birds. Its length from the tail to the tip of the bill is about five and a half inches, and the greatest expansion of the wings is minic inches. The bill is white, tipped with black; the forehead and throat scarlet, the head black, the back

from cricket in affording less violent exercise; and it may be engaged in by the old as well as the young. It is a very ancient game in Scotland, but the exact period of its introduction is unknown. It is played with a ball and clubs, on links or downs. The ball is of gutta-percha, painted white, and about an inch and a half in diameter. The clubs are of various kinds, according as the object may be to send the ball a long or a short distance, to raise it out of an awkward position, &c. The shaft is of considerable length, and is unusily made of hickory or lancewood, while the head position, ac. The shaft is or considerable length, and is usually made of blokory or lancewood, while the head is large and flattened, loaded with lead behind, and faced with horn. Some of them have iron heads for striking the ball in certain positions. The principal clubs are the play-club, putter, spoon, sandiron, and cleek; but sometimes there are several kinds of some of these used by players. The game is played on extensive links, and to increase the hazard of the game, and call forth the skill of the players, it is of advantage that the surface be here and there diversified by knolls, that the surface be here and there diversified by knolls, sandpits, and other obstructions. A series of small round holes about four inches in diameter, and perhaps the same in depth, usually several hundred yards spart, and disposed so as to form a circuit or round, composed probably of six or eight of them; but much depends upon the nature of the ground. The game is proparly played by only two persons; but sometimes there are two or more persons on each side, and then those on one side strike the ball alternately. The object of the game is to drive the ball from one hole into another with the fewest number of strokes, and the nerson who with the fewest number of strokes, and the person who puts in his ball with the fewest number of strokes is said to gain a hole. The match is usually decided by the greatest number of holes gained in one or more rounds. Each person is usually attended by a caddy, or servant, who carries his clubs, assists to find his ball, &c. Golf is a most pleasant and healthy enjoyment, affording not only an agreeable excitement, but abundant healthful exercise in the open air. It demands a very considerable degree of skill to excel in it, requiring some strength of arm for the long distances, and a good eye and fine steady hand for the short ones, with some skill, in order to avoid the hazards or obstructions. Golf is much played on Bruntsfield Links, near Edinburgh, and on the links at Musselburgh, North Berwick, St. Andrew's, Montrose, Aberdeen, &c. with the fewest number of strokes, and the person who Aberdeen, &c.

Aberdeen, &c.
GOLLATH BRETLE, go-li'-ath bee'-ti (Goliathus Druwii), comes under the general fam. of Cetoniida, a class
of coleopterous insects which belong to the Lamellicornes, or Pentamera. This family bontains several
sub-genera; but that which is generally known as the
Goliath beetle is the Goliathus cacious, which is a
native of Africa and South America. This insect is
remarkable for its large size; and, on account of its
beauty and the difficulty of obtaining specimens, it is
much prized amongst collectors. The Goliaths beauty and the difficulty of obtaining specimens, it is much prized amongst collectors. The Goliaths are said to be roasted and esten by the natives of the countries they inhabit, who deem them a great dainty. It is said, also, that sometimes £40 or £50 has been known to be given by entomologists for specimens of this insect, and that even now they fetch generally £5 or £61 The Goliathus polyphemus is another variety of this species, as is also the Goliathus micans, the latter of which changes its colour as it is held in different positions to the light. From the reason already given, of its rarity, not much is known as to the habits of either species of this insect.

GOMEON PALM, go-ma'-to (Saguerus GOMEON PALM, go-ma'-to (Saguerus

of either species of this insect.

GOMATO, or GOMMUTI PALM, go-ma'-to (Saguerus saccharifer, or Areng), a species of palm, found in the Molnocas and Philippines, which supplies abundance of sugar. Palm sugar is generally obtained from the juice which flows out from different palms upon wounding their spathes and adjacent parts. It is commonly known in India by the name of jaggery. The juice of the gommuti palm, when fermented, produces an intoxicating liquid or toddy. In Sumatrs it is fermed neva, and a kind of arrack is distilled from it in Ratavis. From the trunk of this palm, when exhausted permed nevo, and a kind of arrack is distilled from it in.

Batavia. From the trunk of this palm, when exhausted of its saccharine juice, a good deal of our commercial sage is obtained. A single tree will yield from 150 to 200 lbs. of sago. The juice of the fruit is very acrid. The stiff strong fibre known under the name of Gommut, or Ejow fibre, is obtained from the leaf-stalks, and is extensively used is the manufacture of cables 353 and various kinds of ropes.—Ref. Bentley's Manual of

and various kinds of ropes.—Ref. Bentley's Manual of Botany.

GONDOLA, gon'-do-la (Ital.), a peculiar kind of boat used at Venice for the same purposes as cabs and carriages in other cities. They are usually about thirty feet long, five in breadth, and light and elegant in form, having high prows, some of which are of elaborate workmanship and exquisitely carved. About the centre a cabin is erected for the passengers, which is carpeted, hung with curtains, and fitted with stuffed cushions. By the ancient republic a law was passed, ordaining that all these boats were to be painted black and hung with black cloth, except those for the use of foreign ambassadors and for state purposes. The boatmen who navigated these boats were called gondolieri, and were a very important body.

GONG, gong (Ang.-Sax.), a pulsatile musical instrument, used in Asia chiefly to give a national cast to the music, or to awaken surprise and arouse the attention of the auditors. It is of a shallow, circular, concave form, and is made of a composition of silver, lead, and copper, while its tones, which are anything but musical, are produced by striking it with a kind of drumstick, having, head covered with leather.

GONIOMETER, gon-com's-ter (Gr. gonia, an angle; mateur. a measure), an instrument for measuring cateur.

Grumstick, naving, head covered with leather.
GONTOMETER, go-ne-ow-e-fer (Gr. gonic, an angle;
metron, a measure), an instrument for measuring
angles, and especially for determining the angles at
which the planes of crystals are inclined to one
another. The ordinary goniometer is made on the
principle, that when two straight lines intersect one another. The ordinary gonometer is made on the principle, that when two straight lines intersect one another, the opposite angles are equal. This instrument, however, is incapable of giving accurate results, on account of the ordinary minuteness of the planes and frequent irregularity of the fracture. The reflective gonometer, invented by Dr. Wollaston, is the instrument most used by mineralogists. The principle upon which it is constructed depends upon the law of optics, that the angle of reflection is always equal to the angle of incidence. It consists of a brass circle, graduated on the edge, and furnished with an index, by which the divisions can be accurately noted. The circle moves in a vertical plane, and is supported on a stand. To one extremity of the horizontal axis movable pin is attached, having a slit for the purpose of receiving a small brass plate. The crystal to be examined is attached to this plate by means of a piece of wax, so that it may project over the edge of the plate; the pin, which is provided with a vertical and horizontal movement, is then raised or lowered till the reflection of any convenient object above seems to reflection of any convenient object above seems to coincide with some other object beneath. When the goniometer is thus adjusted, the graduated circle is turned until a similar reflection is obtained from the contiguous face of the crystal; the arc which the circle will then have described will be found to be equal to the supplement of the angle formed by the equal to the supplement of the augle formed by the two faces of the crystal. In order, however, to avoid calculation, the supplements of the angles are marked on the limb, and may be read off with considerable securacy by means of the vernier.

GOOD BERLYIOUR, SECURITY FOR (Ang. - Sax.), in Law, consists in a person being bound, with one or more sureties, in an obligation to the crown to behave well or he of good behaviour, either generally or ana-

more sureties, in an obligation to the crown to behave well or be of good behaviour, either generally or specially, for a certain time. If the condition of the said obligation be broken by misbehaviour, the party and his sureties become debtors to the crown for the several sums in which they were respectively bound. A justice of the peace may demand security for good behaviour, according to his discretion, when he sees cause, or at the request of any other person under the queen's protection.

Geom. Chart (Lat. summum bonum), is a phrase

queen's protection.

GOOD, CHIEF (Lat. summum bonum), is a phrase sometimes employed in Phil. to denote that in the prosecution and attainment of which the progress, perfection, and happiness of human beings consist. An inquiry into the chief good is an inquiry into what constitutes the perfection of human nature, the shot of all religion and all philosophy. (See ETRICS.) GOODENIAGEM, good-en-c-u'-s-c-e (in honour of Dr. Goodenough, bishop of Carilele), in Bot., the Goodenia fam., a nat. ord. of Discovitedones, sub-class Corollidora, consisting of unimportant herbs, or rarely shrubs. They are principally natives of Australia and the islands of the Southern Ocean. The species Scavols

## Good Friday

Taccada has a soft and spongy pith, which is employed by the Malays to make artificial flowers and ornaments. By the Malays to make artificial nowers and ornamenta.

Good Farmay is the name given to the Friday before
Easter, the anniversary day of our Saviour's crucifixion. It is termed good as denoting the benefits which
have flowed from Christ's death; and it has been observed as a sacred day from the earliest ages of Chrisserved as a sacred day from the earliest ages of Christianity. In the Roman Catholic church this day is observed with much ceremony. The mass is celebrated, but the elements are consecrated not on this day, but the day before; the pricate and attendants are robed in black, in token of mourning; the usual acclamations and doxologies are omitted; no bell is rung; the altar is stripped of its ornaments; none bow the knee in prayer, because in this way the Jews reviled Christ; the kiss of charity is omitted, because Judas betrayed his master with a kiss. The adoration of the cross, or, as it was anciently called in England, "creeping to the cross," is observed on this day; all the congregation approaching, and upon their knees kissing, a figure of our Saviour upon the cross, placed upon the altar. The offices called Tenebra (darkness) are sung on this day, as well as upon the day preceding and succeeding. It is so called from the lights of the church being for a time extinguished, to symbolize the darkness at our It is so called from the lights of the church being for a time extinguished, to symbolize the darkness at our Lord's cruciffxion; and nearly at the end of the service, and amid solemn silenge, there is a tremendous noise, to denote the rending of the veil of the temple. In the English church Good Friday is also observed with great solemnity, and all business is suspended. A sermon used to be presched at St. Paul's Cross in the afternoon, at which the lord mayor and aldermen attended in their robes. The practice of esting "cross buns" on this day, which is generally observed in England, is a remnant of Roman Catholic times, though it has now no religious import.

Goods and Chattels. (See Chattels.)

though it has now no religious import.

Goods, Finder of. (See Finder of Goods.)

Goods in Communion, in the law of Scotland, are
the movable subjects belonging in common to husband
and wife. They comprehend all the movable property
belonging to either of the parties, except such as have
been given to the wife expressly, excluding her jus
maritis and the wife's paraphernalis, regarding which
there is an implied exclusion of the jus mariti. The
husband has the uncontrolled administration of the
codes in communicy during the subjectance of the nusband has the uncontrolled administration of the goods in communion during the subsistence of the marriage. Formerly, if the marriage had not subsisted a year and a day, or produced a living child, the goods in communion returned to the husband, and wife, or to their representatives, as nearly as might be in the proportions in which they were contributed. If there were no child of the marriage on its dissolution, the goods were divided into twe equal parts, one of which belonged to the survivor, the other to the next of kin of the deceased. If there were children, the division was three-fold, one third falling to the children as

was three-fold, one third falling to the children as legitim. The share of the surviving wife was called jis. relictes; that of the husband's representatives, the dead's part. By 18 & 19 Vict. c. 23 (1855), this was all altered, and the representatives of a wife who predeceases her husband have now no right to suy share of the goods in communion, and no bequest by her can affect these goods. Ref. Bell's Dictionary of the Law of Scalland, by G. Ross, Edin. 1861.

Good-will, in legal or commercial language, denotes the custom of any business or trade,—that interest in it which is sold along with the goods and premises. By disposing of the good-will, the seller binds himself to do everything in his power to advance the interests of his successor in the business, and to recommend him to his customers. It is also usual to specify that the seller shall not enter upon the same business within a certain distance of that which he has sold. Such a contracts good at law, and the party infringing it is contract is good at law, and the party infringing it is fiable in damages.

GOOSE, goose (Sax. gos, Lat. anser), belongs to the order Natatores, Anseres, or Palmipedes, of the general family of Anatides. The following are its

#### Goose

of the body; the tarsi long, the hind toe free, articulated upon the tarsus. The general recognized type of the whole class is the Anser wiveus, or snow-goose of Pennant and Wilson. This bird feeds principally on rushes and insects, and in the antumn on bergies. It is found generally in the barren regions of North America, where it breeds in the most prolife manner. The grey-log, or common wild goose, is the origin of the domestic goose; and, according to Pennant, is our largest species of this family. The heaviest weigh about 10 lbs., their length being 2 feet 9 inches and their extent five feet. The bill is large, and of a flesh-colour tinged with yellow; the back grey; the breast and belly whitiah, tinged with grey or ash-colour; and the wings and fail generally pure white, or at most merely tinged with the grey tint which prevails, more or less, over the whole body. It principally inhabits the sea-shores and marshes of oriental countries, and it rarely advances northward above the latitude of 55°. The tame goose is one of the most useful of birds to man, whether it is considered with tenest to it fields on it. The tame goose is one of the most useful of birds to man, whether it is considered with respect to its flesh or its feathers. The naturalist Pennant writes that they are kept in "vast multitudes in the fens of Lincolnshire; a single person has frequently 1,000 old geese,

GWESE.

each of which will rear seven; so that towards the end each of which will rear seven; so that towards the end of the season he will become master of 8,000. I beg leave to repeat here a part of the history of their economy from my Tour in Scotland, in order to complete my account. During the breeding season these birds are lodged in the same houses with the inhabibirds are lodged in the same houses with the inhabitants, and even in their bed-chambers: in every spartment are three rows of soarse wicker pens placed one above another; each bird has its separate lodge divided from the other, which it keeps possession of during the time of sitting. A person called a gozzard, that is goosehord, attends the flock, and twice a day drives the whole to water, then brings them back to their habitations, helping those that live in the upper stories, without ever misplacing a single bird. The geese are plucked five times in the year; the first blucking is at Lady-day, for feathers and quills: and geese are plucked five times in the year; the first plucking is at Ledy-day, for feathers and quills; and the same is renewed four times more between that and Michaelmas for feathers only. The old geese submit quietly to the operation, but the young ones are very noisy and unruly. I once saw this performed, and observed that goalins of six weeks old were not sparsel; for their tails were plucked, as I was told, to habituate them early to what they are to come to. If the season prove cold, numbers of the geese die by this barbarous custom. When the flocks are numerous, about ten pluckers are employed, each with a coarse apron up to his chin. Vast numbers of geese are driven annually to London to supply the markets; among them all the superannuated geese and ganders (called the 'cagmags'), which by a long course of plucking prove uncommonly tough and dry. The feathers are a considerable article of commerce; those from Somersetshire are esteemed the best, and those from Somersetshire are esteemed the best, and those from Ireland the worst." The Bean-goose (Anser order Natatores, Anseres, or Palmipedes, of the segtum) is a regular winter visitant to England, which general family of Anatida. The following are its country it generally arrives in in October, seldom characteristics:—Beak about the same length as head, covered by a cere or skin; the lower mandible is overed by a cere or skin; the lower mandible is in the fur-countries of North America. When it inferior in size to the upper; nostrils lateral in form and placed towards the middle of the beak, which is otherwise killed in large numbers, with sticks and pierced anteriorly; the legs placed under the centre

Gorilla

on for the winter, during which rigorous season it is one of the principal articles of diet to the inhabitants one of the principal articles of diet to the inhabitants of the fur-countries. The plumage of this bird is generally grey, and in its contour it approaches more closely to the swan (eygnus) than any of the other branches of the family duatides. The Brent goose, or Anser torquatus, is another variety of this tribe, and it is one of the smallest, as well as the most numerous in the British islands. It is a regular winter winter winter to the aboves of our waviting admitting a winter visitor to the shores of our maritime counties, says Yarrell, and it remains with us through all the cold months of the year, its predilection being more for the south and east coast. In the adult male, the bill is black, and only an inch and a half in length; the index more dark because the state of the south and east coast. bill is black, and only an inch and a half in length; the irides very dark brown, almost black; the forehead low, the head small and black; the neek all round black, except a small patch on each side, which is white, but marked with a few regularly-placed black feathers; back, scapulars, wing-coverts, and tertials, dark brownish black, the edges a little lighter in colour; primary and secondary quill-feathers black; the rump black; upper tail-coverts white; tail-feathers black; upper part of the breast black; lower portion of the breast and the belly slate-grey, with lighter coloured margins; vent and under tail-coverts white; legs, toes, membranes, and claws black. This description is taken from Yarrell's Kizetory of British Birds, in which it is membranes, and claws black. This description is taken from Yarrell's History of British Birds, in which it is likewise added that the general length of the Brent goose is twenty-one inches, and the expanse from the carpal joint to the end of the wing thirteen inches. It may be mentioned that the livers of geese are esteemed as great a dainty in the present day as they were amongst the ancient Romans; a dish termed pâte de fois gras being made of them, which is a great favourite with epicures, and consequently high in price.—Ref. English Cyclopeala, section Natural History; Yarrell's History of British Birds. (See also Ganner.)

a knot made in the harness of a charlot by Gordius, king of Phrygia, which knot was so intricate as to baffle every attempt to untio it, or even to find out where it hegan or ended. The oracle of the day having declared that he who succeeded in solving the complication should be the conqueror of the world, Alexander the Great determined to effect it if possible. Deliberating that if he failed, his followers would be dispirated, he determined to separate it with his sword, and with one blow he cut the momentous Gordian that the weak fraught with such interest to the and with one blow he cut the momentous Gordian knot, which was fraught with such interest to the whole world. According to Quintus Curtius, he thus fulfilled the oracle or evaded it; but Aristobulus, however, gives a different version of the affair. The expression cutting the Gordian knot has consequently been used by the moderns to signify eluding any difficulty or task by hold or unusual means. The story itself is related in Plutarch's Life of Alexander.

Gorge, gorje (Fr.), in Mil., the name that is given to the entrance of any work, or that part which is open to the rear between the inner extremities of its flanks or faces. Thus the gorge of a ravelin is the space facing

or faces. Thus the gorge of a ravelin is the space facing the main works behind it, between the extremities of the main works beamed it, between the extremities of its faces which meet in a salient angle towards the front; and the gorge of a bastion is that side of the irregular pentagon which forms the outline of the work and lies between the interior extremities of its work and lies between the interior extremities of its flanks, where they join the curtains on either side. The lines formed by the prolongation of the curtains on either side of a bastion to a point in its capital within the interior of the work are called its demi-gorges. It is also the name of a concave moulding used in Arch., and the entrance to a narrow pass or defile between mountains.

GORER, gor'.jet (Fr. gorgette), a small piece of steel armour, intended to protect the neck and throat. It was worn by officers in the army long after the use of armour had been shaudoned.

armour had been abandoned.
GORILLA, go-ril-la (Troglodytez Gorilla), a species of large spe which inhabits Western Africa. It is generally referred by naturalists to the same genus with the chimpanzee, but M. Geoffroy St. Hilaite has endeavoured to establish a separate genus for it. For a great number of years there was a vague tradition, unaubstantiated by reliable evidence, that apes of great size were to be seen on the west coast of Africa.

It was not, however, till 1847 that the gorilla absolutely became known to naturalists. A skull of one of these large apes was sent to Dr. Savage, of Boston, by Dr. Wilson, an American missionary on the Gaboon river; and during the same year Dr. Savage, writing to Professor Owen concerning the gorilla, says, "As yet I have been unable to obtain more than part of a skeleton. It belongs to the Simiade, and is closely allied to the orange proper. It reaches pearly, if not quite, the orango proper. It reaches nearly, if not quite, the height of five feet in the adult state, and is of a large size. I am considerably in doubt in regard to its identity with an animal said to have been known to lockinty with an animal said to have been known to Buffon as a large species of orang-outang, under the name of pongo." Since that period akeletons and skins of the gorilla have not only been received, but also considerable information concerning the animal's habits and mode of living. In M. Du Chaillu's "Explorations and Adventures in Equatorial Africa," there are some very interesting accounts of the gorilla. Considerable doubt has been east over several of the siderable doubt has been cast over several of the statements in the work, but the narrative is considered statements in the work, but the narrative is considered trustworthy by Professor Owen and several of the highest scientific authorities. The points of difference between the gorilla and the chimpanzee are as follows: The gorilla is much longer than the latter animal; the ordinary height of a full-grown male is between 5 feet inches and 5 feet 8 inches, and it is probable that many of the largest size exceed six feet in height. Its strongth is transplayer and its akeleton indicated. many of the largest size exceed six feet in height. Its strength is tremendous, and its skeleton indicates great power in the jaws and limbs. The bony ridges above the eyes are very prominent, and the skull of the male exhibits a large occipital ridge on the top of the head. The brain is small, and the nasal bones project more than in the chimpance: these peculiarities give to the animal a hideous resemblance to the human feet. The internal large and large market fits feet was human face. The jaws and lower parts of the face prohuman face. The jaws and lower parts of the face project very much, and the teeth do not form an unintorrupted serice, as in man. The canine teeth are very
large, and the molers bear a greater proportion to the
incisors; thus again approaching the features of a
human being. It is very broad across the shoulders,
has thirteen pairs of ribs, and approaches nearer to the
human form in the shape of the pelvis than any other
have The legs atthough shorter in proportion than has thirteen pairs of ribs, and approaches nearer to the human form in the shape of the pelvis than any other ape. The legs, although shorter in proportion than those of a man, are longer than those of the chimpanzee. When standing erect, the arms nearly reach the knees. The feet age formed for walking on the ground, and the great toe is a true thumb. The hands are remarkable for their great size and strength, the fingers being short but very thick. The skin of the gorilla is black in colour and covered with dark grey hair, which changes to a tawny brown on the head. The hair is longest on the arms. The face is hairy, but the chest is bare. The mouth is large and wide, and thore is scarcely any appearance of neck. The year are much sunk, and in general the countenance is marked by a ferocious scowl. It is a voracious feeder, its food being crollaviely vegetable; and its belly is very large and prominent. Gorillas are not gregarious in their habits; they generally live on the ground, but spend much of their time in climbing trees in search of food. Their immense strength enables them to defend themselves against beasts of prey. They live in the densest parts of the tropical forests, and are much dreaded by the inhabitants. As yet the gorilla has not been tamed, and it would appear as if it reversions. forests, and are much dreaded by the finabitants. As yet the gorilla has not been tamed, and it would appear as if it were incapable of being so in an adult state. Many stories are told of the gorilla being made to work by the inhabitants in some parts of Western Africa: these narratives are perfectly fabulous. In Du Chaillu's work there is a description of two species of Trotlothese narratives are perfectly fabulous. In Du Chaillu's work there is a description of two species of Troglodytes discovered by himself,—one the koole-kamba, and the other the nahigombouvé, which is smaller than the gorilla, and remarkable for a shelter which it makes with leaves in order to protect itself from the rain. In shape this shelter is not unlike an umbrella. The gorilla is called by the inhabitants ngina or ingeena.—Ref. Transactions of the Zoological Society, vol. iii., and Du Chaillu's Exploration and Adventures in Royatorial Africa.

vol. III., and Dn Chaillis Exploration and Activates in Equatorial Africa.

Gonv Daw, go'-re dow, is a term frequently applied to the dusky red film seen upon the damp walls off cellars, or other moist situations. Its diagreeable and alarming nature is due to the unpleasant fact of its resembling the stains of blood.

#### Goshawk

GOSHAWK, gos'-hawk (Sax. goshafoc, goose-hawk), (Astur palumbarius), is a bird which belongs to the general fam. of the Aulconida, of which it is more or less a type. Its generic characters, according to Yarrell, are a sollows:—Bill short,

THE GOSHAWK.

bending from the base, with the cutting-edge of the ting-edge of the upper mandible produced, — thus forming a festoon; nostrils oval. Wings short, reaching only to the tail-feathers, the fourth quill-fea-ther being the long-est. The legs stout, andthe tarsicovered in front with broad scales. The toes of moderate length, the middle toe being the longest, and the laterals nearly equal in length.
The great distinguishing points between the goshawk and the falcons, are the lobe, or festoon,

and the falcons, are the lobe, or festoon, instead of the sharp tooth on the cutting edge of the upper mandible, and the short and rounded form of the wings. Although inferior in powers to the falcon, the goshawk is the best of the short-winged lawks; but its habits and mode of flying its game are very different,—as it does not swoop, but glides along at a short distance from the ground, in an even line with the bird it pursues. A full-grown female measures from 23 to 25 inches in length; and the males one-third, or sometimes one-fourth less. When adult, the plumage is generally similar. The heak is horn-colour, or bluish-black; the cere and rides yellow; the top of the head, the whole of the back, upper surface of the wings and tail-feathers, of a dark greyish-brown colour; in the female this tint is more of a clove-brown. The upper surface of the tail-feathers is bound with even a darker brown colour; while a band of white, variegated with spots and bars of black, passes over the cere, the cyds, cheeks and car-coverts, the nape of the neck, throat, threast, belly, and thighs. The under tail-coverts are white, the cere, cheeks, and ear-coverts, greyish-brown, forming an elongated dark patch on the side of the head; while the legs and toes are yellow and the claws black. The goshawk is used principally for the pursuit of harse, rabbits, and partiages, on account of its low flight. It is not very eager in huuting its prey. ratio of hares, rabbits, and partridges, on account of its low flight. It is not very eager in hunting its prey, as, if its speed is eclipsed, it sits patiently on a tree and waits for other game to present itself.—Ref. Yarrell's British Birds.

British Birds.

Gospel, gos'-pel (Sax., good news; Gr. to euaggelion), denotes the good news of the coming of Christ, and is, by Christians, employed to signify the whole dootrine of the Christian religion,—more particularly the books containing an account of the life of Christ,—i.e., those of Matthew, Mark Luke, and John, are termed the Gospels. There exist a number of apocryphal gospels, which, however, have generally been rejected by the Church, and which abound with absurd and improbable stories regarding the life of Christ, so as to leave no doubt as to their spuriousness.

## Gossypium

however, not the least shadow of evidence of the record of which it is impossible to ennecive could have passed away. This is only another instance of the way in which men, in order to explain a minor difficulty, are often led to entertain even the wildest hypotheses.

Gossip, god-eip (Sax.), was a name formerly given, in England, to the sponsors at baptism. It is formed from God and siò (affinity), and hence denoted one who was considered to have a kind of spiritual affinity

to another.

To another.

GOSSTRUM, gos-stp'-s-um (Lat. gossipeum, the action plant), in Bot., the cotton plant, a gen. of the nat. ord. Malvacea, or Mallow fam. Several species furnish cotton, which consists of hairs covering the seeds. These hairs upon the seeds, and the occurrence of three leafy bracts, united at their base outside the flower, constitute the distinctive characters of the genus. From the importance of cotton as a raw material, the genus Gossppium must be regarded as one of the most valuable to man in the whole vegetable kingdom. At the present moment (January, 1863) nearly half a million of operatives in Lancashire and the adjoining counties are more or less dependent upon the parcochial and charitable funds, in consequence of the suspension of the cotton trade with Americs. There appear to be four distinct species from which our commercial cotton is derived. Many other so-called species have been described, but they are proour commercial cotton is derived. Many other so-called species have been described, but they are pro-bably mere varieties. The first cotton fabrics were manufactured from the hairs of the species G. herba-ceum, the common cotton-plant of India. The stems are less woody than in other species; hence its specific name, which signifies herbaccous. It is a pretty plant, and rises from eighteen inches to two feet in height during the first year of growth. It is usually cut down annually; but if allowed to grow, it will attain cut down anusulty; but if allowed to grow, it will attain a height of five or six feet, and its branches will become rather woody. All the younger parts of the stem are covered with short hairs, and marked with black spots. The flowers are bright yellow, each petal being marked with a purple spot near the base. The flower is succeded by a fruit, which gradually becomes dry, and then bursts into three or four valves, when the cottonwool is seen issuing from it in all directions. This is the Surat cotton of commerce. The cotton is generally white; but much of that produced in China is of the yellow or tawny colour. becalled to fabric called white; but much of that produced in Collins to the fabric called "Nankeen." G. arboreum, the tree-cotton, is another Indian species, but, unlike the last, it assumes the aspect and dimensions of a small tree, from fifteen to twenty feet in height. The flowers are of a bright red aspect and dimensions of a small tree, from fifteen to twenty feet in height. The flowers are of a bright red colour. The cotton hairs are remarkably soft and silky, and are woven by the natives into a very fine musiin, used for turbans by the privileged religious classes only. G. barbadense is the species which yields all our best cotton. It is called the Barbades, or Bourbon cotton, but does not appear to have been originally a native of the New World. It is a perennial plant, and has a shrubby stem, from six to fifteen feet in height. The flowers are yellow, like those of G. herbaceum, and have a dark spot at the base of each petal. The fruit is capsular, and contains in its interior from eight to twelve black seeds, which, on being freed from the ootton-wool, are found to be destitute of down, unlike those of the preceding species, which are covered with firmly-adhering short hairs. The plant was introduced into Georgia from the Bahama Islands, where it had been grown from seed obtained in the West Indies. In the small American islands which fringe the coast of Georgia from Charlestown to Savannah, Indies. In the small American islands which irrings the coast of Georgia from Charlestown to Savannah, this plant has produced the celebrated Sca-island cotton, which is surrivalled for the length of its staple, its strength, and its silkiness. This cotton, when cultivated in the cooler and drier climates of the hill absurd and improbable stories regarding the life of Christ, so as to leave no doubt as to their spuriousness. The authenticity of the four gospels rests upon the clearest evidence. In the latter half of the 2nd cotton, which is unrivalled for the length of its staple, clearest evidence. In the latter half of the 2nd cotton, which is unrivalled for the length of its staple, cotton, which is unrivalled for the length of its staple, cotton, which is unrivalled for the length of its staple, cotton, which is unrivalled for the length of its staple, cotton, which is unrivalled for the length of its staple, cotton, which is unrivalled for the length of its staple, cotton, which is unrivalled for the length of its staple, cotton, which is latter and its silkiness. This cotton, when cultivated in the coest of Georgia from Charlestown to Savannah, this plant has produced the celebrated Sea-island cotton, which is unrivalled for the length of its staple, cotton, which is unrivalled for the length of its staple, cotton, which is unrivalled for the celebrated Sea-island cotton, which is unrivalled for the length of its staple, cotton, which is plant has produced the celebrated Sea-island the celebrated Sea-island cotton, which is unrivalled for the length of its staple, cotton, which is unrivalled for the length of its staple, cotton, which is plant has produced the celebrated Sea-island cotton, which is unrivalled for the length of its staple, cotton, which is plant has produced the celebrated Sea-island cotton, which is plant has produced the celebrated Sea-island cotton, which is plant has produced the celebrated Sea-island cotton, which is unrivalled for the length of its staple, cotton, which is plant has produced the celebrated Sea-island cotton, which is plant has produced the celebrated Sea-island cotton, which is unrivalled to the cotton, which is plant has produced the celebrated Sea-island cotton, which is unrivaled cotton, which is unrivaled cotton, which is unrivalled to the cotton, which is plant has produced

island and Egyptian, these South-American cottons obtain the highest price in the market. Cotton is now extensively cultivated in South Africa, in the West Indies, and in Australia; but it will be long before the supplies from these parts can compete with those from the Southern Confederacy. The seeds of the cotton-plants, after the cotton has been separated from them, being supplied to average visid a fixed city. on being submitted to pressure, yield a fixed oil which may be used for burning in lamps. If examined under the microscope, the cotton hair will be found apparently to consist of two delicate transparent tubes, apparently to consist of two delicate transparent tubes, the bne twisted round the other. If, however, the hair be examined in its young state, it will be found to be an untwisted cylindrical tube. Its changed appearance when it reaches to maturity can be accounted for by the circumstances under which it is developed. As the seeds and hairs grow, the espatles do not appear to expand with equal rapidity; and, consequently, the hair is exposed to pressure on all sides. The result of this is, that the hair collapses in the middle, leaving a half-formed tube on each side. These uncollapsed portions of the hair give it the appearance uncollapsed portions of the hair give it the appearance of a flat ribbon, with a hem or border at each edge, of a flat ribbon, with a hem or border at each edge. The hair does not, however, grow out straight, but, coming in contact with other hairs and the sides of the capsular fruit, it becomes twisted. This twisting is undoubtedly the great fact that makes the cotton hair of value to man. There are many hairs, such as those of the cotton-grass and the Bombaz, which are as long and apparently as strong as those of the Gosspium, but which, failing in this irregularity of surface, are utterly incanable of being twisted into a surface, are utterly incapable of being twisted into a thread or yare. The twisting gives the cotton hair the power of uniting with its fellows, and forming with them a cord strong enough to be woven.

LAGEM a COTA SETONS GROUND TO BE WORD.

GOTHA, ALMANAGE DB, go'-thd, is a celebrated publication which takes its name from the city of Gotha, in Germany, where it is published. It is a small pocket volume, 32mo, containing nearly 1,000 pages, and has now reached the hundredth year of its existeno mas now rescued too indured a year of the stete-ence, the first volume having appeared in 1763. It is chiefly remarkable for the large amount of statistical and political information which it contains, regarding all the different states of the world; and as these are always prepared with care from the most reliable always prepared with care from the most reliable sources, it is received as an authority upon such points. So careful are the publishers to maintain the sharacter of the work, that in many cases the date of printing off is marked at the bottom of a page to show that the editor is not responsible for changes after that time. It is divided into four distinct parts,—Genealogy, Diplomatics, Statistics, and Chronology. The first part gives an account of the reigning and princely families of Europe, with the dates of the birth, marriage, children, &c. of the several members. The diplomatic portion gives a list of the ambassadors, plenipotentiaries, charges d'affaires, &c., with the date of their nomination, of each government; the secretaries, attachés, &c. to the several embassies or legations; and the consuls-general and consuls stationed in all the principal towns. It also gives alist of the various ministers and other administrative authorities of each nons; and the consuis-general and consuls stationed in all the principal towns. It also gives a lists of the various ministers and other administrative authorities of each state, with the date of their nomination, &c.; also the names of the principal military authorities, the highest ecclesiastical dignitaries, and the principal officers about each of the courts, with any important changes that may have taken place in its constitution. The statistical portion gives the superficial area of each of the different countries, according to its general divisions, as counties, provinces, circles. &c.; the number of inhabitants in each of these divisions, according to the latest census; the numbers belonging to the various sects. &c.; the financial condition of each country, its income, expenditure, national debt, &c.; its military condition, the amount and divisions of its army, navy, militia, &c. Under the head of Chronology it gives a list of the principal events that have happened during the year, and which are either of general interest or of historical importance. It was originally printed in German; but when Napoleon I., who exercised a rigid supervision of this small was originally printed in German; but wash rapheon 1, who exercised a rigid supervision of this small publication, became emperor, the language was changed to the French, in which it has since continued to appear. This almanac has the character of being slow to recognize political changes, and for years after

the Revolution, it continued to represent Louis XVII.

the Revolution, it continued to represent Louis Avil. as the religning monarch in France.

Gothic Architecture, goth'ak, the name given to the style of architecture that was adopted by Buropean nations generally during the mediewal ages. By some the term is confined to that form of architecture which the term is confined to that form of architecture which is peculiarly characterized by the pointed arch, while others consider that Romanesque architecture, which is distinguished by the use of the round arch in every form, and from which the pointed style of architecture was gradually developed, should also be included under this appellation. Adopting the latter and more comprehensive view of the subject, we may therefore, consider Gothic architecture to consist of two grand divisions—the Romanesque or round-syched Gothic divisions—the Romanesque or round-syched Gothic consider Gothic architecture to consist of two grand divisions,—the Romanesque, or round-arched Gothic, and the Medieval, or pointed Gothic, to which the term "Gothic" is more particularly applied, and, indeed, generally restricted. The early forms of the round-arched Gothic were based on the architecture that prevailed in ancient Rome about the time of the Christian era, in which the circular arch is a common feature. Prior to the dissolution of the Western empire, and even before the division of the great empire of Rome into the rival sovereignties of the East and West, the churoffes and public buildings that were erected in various parts of Italy, although they were for the most part copies of the old Roman basilicas, began to exhibit new features in the general plan of construction and ornamentation; and as soon as the cessation of the internal strife and the flerce assaults of predatory tribes of northern and central Europe, which preceded the overthrow of the Western empire, again permitted men to turn their attention to the Christian era, in which the circular arch is a common which preceded the overthrow of the Western empire, again permitted men to turn their attention to the development of the arts of construction and decoration, these new features expanded into a distinct style, marked with its own special characteristics, that is now known as Romanesque. (Nes Romanesque Arentracture). Under this style of architecture those known as the Lombardic and Norman styles are properly classed; and the oldest eccleristics buildings in England, such as St. Martin's Church, Canterbury, which was partly rebuilt in the 12th or 13th century, Earl's Barton Church, Northamptonshire, and the naveof Rochester Cathedral, which amptonshire, and the nave of Rochester Cathedral, which ampronsure, and the naveol Kochester Cathedral, which are assigned to the Anglo-Roman, Anglo-Saxon, and Anglo-Norman styles respectively, also belong to this division of Gofnic architecture. During the 11th, and the early part of the 12th century, Gothic architecture was in a state of transition from the first stage to the was in a state of transition from the first stage to the second, round and pointed arches being used indiscriminately and in the cathedrals and churches that were erected in England during this period, such as Canterbury Cathedral, the ruins of Glastonbury Abbey, and the Abbey Church of St. Albans; and in France, nearly to the close of the 13th century, many of the characteristics of the Romanesque and Fointed styles of Gothio architecture are to be seen in juxta-position. Mediswal, or Pointed Gothic architecture, dates from the middle of the 12th century, and is divided, in England, into three distinct varieties, known as the First, Second, and Third Pointed, or, the Early English, Decorated English, and Perpendicular English styles of architecture. The principal characteristics of these styles, and the period of time during which each was successively the prevailing form of Anglo-Cothic architecture, are mentioned elseof Anglo-Gothic architecture, are mentioned else-where. (See RARLY ENGLISH, DECORATED ENGLISH, where. (See Early English, Decorated English, Perpendicular English.) These three styles were all marked by the use of the pointed arch struck from at wo centres, which varied in form, the arches being termed obtuse or soute as the centres were taken within or without the span of the arch. Of the dif-ferent forms of pointed arches that may be obtained ferent forms of pointed arches that may be obtained by varying the position of the centres from which the ourves that form the arch are described, the equilateral arch, in which the centres coincide with the extremities of the span, is considered as the characteristic of architecture that may be termed purely Gothic. During the prevalence of the Third Pointed, or Perpendicular English style, an arch was introduced which is known as the four-centred or depressed arch, being convexed of accuments of circles struck from four being composed of segments of circles struck from four different centres, and having the point of the arch but a short distance above the span. This arch became the characteristic feature of the Tudor style of archi-

Gotha

tecture (see TUDOE ARCHITECTURE); a style which is generally termed by architects debased English, and which was the last passe of Gothic architecture in England, being the prevailing style, especially in colleges and buildings of a private character, until the middle of the 18th century. From this time few, if any, buildings were erected after the Gothic style in this country, until its revival about 1825, which is mainly owing to the endeavours of A. W. Pugin, an architect of considerable eminence in his profession, to restone a tests for Gothic stylistical energials. restore a taste for Gothic architecture, especially in buildings designed for ecclesiastical purposes, that had long lain dormant. Since that time considerable improvement has been effected in the style of our church architecture; and among other public buildings that have been erected in this style may be named that magnificent structure the New Palace of Westminster. A comparison of St. Paul's Cathedral with Westminster Abbey will at once show the superiority of Gothic ster Abbey will at once show the superiority of Gothic architecture over the so-called classic style for churches and cathedrals; although it must be allowed that, except in the case of the new Houses of Parliament, which has just been cited, it is by no means well suited for buildings designed for the public service, or those of a private character. The chigin of the name is involved in obscurity: it has been shown that the architecture of ancient Rome was the parent source from which Gothic architecture was derived; and although it is certain that the settlement of the Ostrogoths and Langobardi, or Lombards, in the north of goths and Langobardi, or Lombards, in the north of Italy must have had a marked influence on Romanesque architecture, by the introduction of elements derived from the structures of northern Europe, it is equally clear that the origin of this style cannot be attributed to these rude nations, whose knowledge of the art of construction must have been as limited as the degree of civilization to which they had then attained. According to Mr. Bloxam, an eminent authority on English ecclesiastical architecture, the term Gothic was introduced by the architects who flourished at the close of the 17th century, to express the inferiority of medieval architecture, according to their notions, to the classic style, which they were then endeavouring to introduce. French Gothic architecendeavouring to introduce. French Gothic architecture, like that of England, is divided into three styles termed Ogival primitif, Ogival secondaire, and Ogival termed Ogival primitit, Ogival secondaire, and Ogival tortiaire, or Flamboyant; corresponding to our First, Second, and Third Pointed styles in their principal characteristics, and the period of time during which they prevailed.—Ref. Bloxam's Gothic Architecture; Brandon's Summary of Gothic Architecture; Fragusson's Handbook of Architecture; Glossary of Architecture.—Parker Ortical ere,-Parker, Oxford. LITERATURE.

LATERATURE.)
GOTHS, goths (Lat. Gothi, Gotones, Guttones), the name of an ancient people of Germany, who in early times inhabited the coast of modern Prussia, from the Vistula as far as Braunsberg, or Heiligenbeil. The origin of this people has not been ascertained with any degree of certainty. It is generally believed that they once inhabited Scaudinavia, a belief that is both supported by tradition and by the names of places there. The opinion further is, that they came from the south at a period lone anterior to historic records. They are at a period long anterior to historic records. They are mentioned by Pytheas of Marseilles as inhabiting the shores of the Baltic, about the Frische Haff. They shores of the Baltic, about the Frische Haff. They are afterwards mentioned by Tacitus; but from the time of Tacitus, no more is heard of them until the beginning of the 3rd century, when they are spoken of as a powerful nation on the coasts of the Black Sea. In the reign of the emperor Philippus, they took possession of Dacia, and laid siege to Marcianopolis, the capital of Mesia Secunds, which purchased peace for a large sum of money. A few years later, they again extered Mesia, but retreated before the army of Decius, upon which, however, they unexpectedly Decius, upon which, however, they unexpectedly turned, and completely annihilated, near Philippopolis, at the foot of Mount Hæmus (a.n. 259). The following year they again encountered the Roman army, and ing year they again encountered the Roman army, and defeated it with great slaughter, at Forum Trebonii, in Mœsia; the emperor Decius being among the number of the slain. His successor, the emperor Gallas, induced them to withdraw to their own territories, with a large sum of money. They then seem to have expected the statement of the seem to have expected the seem to have expect

tended themselves more to the eastward, and possessing themselves of a fleet, they sailed against Pityus, which they took, and subsequently Trebitond ahared the same fate. In a second expedition they took Chalcedon, Nicomedia, Nicora, Prusa, Apamea, and Cius. In a third expedition, comprising a fleet of 500 vessels, they landed at Cyzicus, ravaged the coast of Attics, took and plundered Athens, Corinth, Argos, Sparts, and many other places. In 269 they undertook another vast expedition, in which they ravaged Crete and Cyprus, and laid siege to Thessalonics; but they were at length defeated in three separate engagement., by the emperor Claudius, with immense slaughter. They, the emperor Claudius, with immense slaughter. They, however, still continued to harass the Roman frontier, and in 272, the emperor Aurelian was obliged to cede and in 273, the emperor Aurelian was obliged to cede them the province of Dacia; after which, there was a period of comparative peace for about fifty years. In 332, their king, Uraric, crossed the Danuhe; but he was at length defeated, and obliged to sue for peace. In the reign of Valens, they carried on a war with the Romans for three years (367-69), but without any decisive result. About this time internal commotions produced the division of the great Gothic kingdom into the kingdom of the Ostrogoths, or Eastern Gothe, who inhabited the shores of the Black Sea, from the Don to the Dnieper; and the Visigoths, or Western Goths, who occupied Dacia, from the Dnieper to the Danuhe. About 375, the Huns invaded Europe from the east, and the Visigoths implored the protection of the emperor Valens, and leave to settle on the east bank of the Danube, which was granted them. The Ostrogoths being refused admission into the Roman erritory, took refuge in the mountains. The oppression of the Roman governors soon drove the Visigoths territory, took refuge in the mountains. The oppression of the Roman governors soon drove the Visigoths to rebellion, and in the war which ensued, they com-pletely defeated the Roman army at Adrianople, in 378, and the emperor Valeus himself lost his life. They threatened Constantinople, but were unable to take it, and afterwards settled in Thrace and Dacia. They soon became so numerous and powerful, that the court of Constantinople saw no other way of securing itself against their attacks than by making them an integral part of the empire. After many vicissitudes, the Ostrogoths also obtained a settlement in Pannonia and Sciavonia, but not till the destruction of the kingdom of the Huns in 453. The Visigoths, in process of time, obtained a degree of power which excited the alarm of Greece and Italy. In 396, Alario made an irruption into Greece, laid waste the Peloponnesus, and became prefect of Illyria and king of the Visigoths. He invaded Italy about the beginning of the 5th century, and by that measure brought on the destruction of the Roman empire, since Stilicho, the Roman general, could only obtain a victory over Alarie, at Verona, in 408, by withdrawing all the Roman troops from the borders of the Rhine. Alarie bimself soon returned to Italy, and sacked Rome in 408, and soon became so numerous and powerful, that the court at versus, in 403, by windrawing all the Roman troops from the borders of the Ithine. Alsrie bimself soon returned to Italy, and sacked Rome in 409, and again in 410. From Rome, Alarie turned to the south of Italy, where death cut short his victorious career. In 412, the Gotth quitted Italy, the south of Gaul having been given up to them; and after having remained there for a short time they crossed the Pyronees and took possession of a large part of Spain, where Athaulf, the successor of Alaric, was assassinated. His successor, Wallis, assisted the Romans against the Yandals sud Alani, in Spain, and was rewarded with a portion of western Gaul. The succeeding kings of the Goths extended their empire, both in France and Spain, and during the latter part of the 5th century it had reached the highest point of its prosperity, its capital being Toulouse. At that time it embraceed the greater part of Spain, and a large portion of Gaul; but after that time the Goths in Gaul were compelled to retreat before the Franks, while in Spain their our anter that the treaths in Gand were compensus to retreat before the Franks, while in Spain their empire was overthrown, about two centuries later, by the Saracens. After the fall of the Western Roman empire, by the invasion of Odoacer, in 476, the eastern emperor, Zeno, persuaded Theodoric, king of the Ostrogoths, to invade Italy in 489. He was successful, and established the kingdom of the Ostrogoths in Italy. Theodoric regions for thirty, they were and greather Theodoric reigned for thirty-three years, and greatly strengthened his power and extended his kingdom; but, after his death, disputes arose as to his successor, and the country became embroiled in civil dissensions. Justinian, the Eastern emperor, in order to profit by these

## Gourd

disorders, dispatched Belisarius to Italy in 526, who took possession of Rome, and, gaining the admiration of the Goths, was invited to become their king. This, of the Goths, was invited to become their king. This, however, he refused, but held the people in subjection to his master. Totila, a noble Goth, rebelled, and made himself master of southern Italy. He was about to destroy Rome, but listened to the remonstrances of Belisarius, that it would add more to his honour to spare it, and contented himself with dispersing the inhabitants, and repeopling it before the arrival of a fresh army from Constantinople under Narses. Totila fell in battle, and his successor, Theirs, shared the same fate: Italy was reconquered, and the Narses. Totals fell in battle, and ins successor, hereas, shared the same fate; Italy was reconquered, and the Gothic monarchy, established by Theodoric, ceased to exist, 554. The Goths, originally savage and barbarous, had become civilized and enlightened before the time of Theodoric. This prince is much praised for his redesting integrity and love of instinct. The public of Theodoric. This prince is much praised for his moderation, integrity, and love of justice. The public buildings of the city were kept in repair, and overseers were appointed to look after them, and to guard the statues. He was slso distinguished in some degree as a patron of the fine arts, science, and learning. Religious liberty was accorded to all; and there is said to have never been in Italy a better administration than that of Theodoric. The Visigoths were the first of all the German tribes to have a written code of laws, which were the first of all the German tribes to have a written code of laws. which was drawn up in the 5th century, half a century before that of Justinian.—Ref. The wild gourd of the Old Testament (2 Kings iv. 39) is supposed to have been the bitter cucumber, or colocynth.

GOUT, gow! (Fr. goutle, Lat. gutla, a drop), in Path., is a painful disease of the joints, generally of the feet or hands, and more particularly of the great toes. It cocurs mostly in porsons advanced in life, and who indulge freely in the pleasures of the table; and is hereditary. The attack is usually precoded by a disordered state of the digestive system, and commonly begins by a painful swelling of the first joint of the great toe. It returns at longer or shorter intervals, when it may attack various other parts; but generally the great toe is the chief seat of the disease. Some times the attack comes on without any previous times the attack comes on without any previous warning; but usually, for some days or weeks before, warning; but usually, for some days or weeks before, the patient has been suffering from indigestion, with diminished appetite, flatulence, costiveness, and a general feeling of lassitude and depression of spirits. He goes to bed, perhaps, in tolerable health, and after a few hours is awakened by the severity of the pain in the great toe, or sometimes the ankle, heel, or calf of the leg. The pain resembles that of a dislocated bone, and is attended with the sensation as if cold water was poured over the part; and this is succeeded by chilliness, shivering, and other febrile symptoms. These gradually abate as the pain increases, and it continues usually to the following night, with sometimes, however, a period of intermission during the These gradually abate as the pain increases, and it continues usually to the following night, with sometimes, however, a period of intermission during the day. The pain is of a burning or gnawing character. The next night, after some time of tossing and restlessness, the patient succeeds in falling saleep; a gentle perspiration breaks out, and he awakes to find himself refreshed and the part comparatively free from pain. On examining the limb next morning, it is found to be considerably swollen, the toe red and shining, and the veins of the foot much distended. There are usually a number of subsequent attacks, becoming less and less severe, before what is known as "a fit of the gout" is over; so that it commonly extends over a period of several weeks, or even months. When the fit is over, the system is relieved, and the person feels, both in mind and body, much better than before the attack. At first, a fit of gout occurs only once perhaps in two or three years; but it becomes by degrees more and more frequent, more severe, and of longer duration every succeeding fit. In its progress, various parts of the body become affected, and translations take place from one joint or limb to another; and after frequent attacks, the joints lose

## Grace

their strength and flexibility, and become so stiff as to be deprived of all motion. Concretions of a chalky appearance are likewise formed about the joints; and affections of the kidneys arise from a deposit of the same kind of matter in them. This matter is a compound of trie acid and soda. The fits are more apt to occur in spring or autumn than at other seasons of the year; probably owing to the variableness of the weather at these times. As the fits become more frequent and severe, so the constitutional derangements become more marked and constant. The appetite fails, indigestion is more constant, there is a tendency to costiveness, the mind becomes restless and tendency to controlless, the mind becomes results and irritable, calcareous deposits are formed in the arteries, calculi form in the bladder, and frequently the heart becomes diseased. Such are the general features of what is termed the regular gout; but there are certain other kinds which differ widely from it in their general other kinds which differ widely from it in their general obsracter. In atonic gout, the disease, instead of manifesting itself in the joints, attacks some of the internal organs, as the stomach, when the patient suffers from indigestion, nauses, vomiting, and severe paine; or the thoracic viscers, when palpitations, fainting, and asfirms arise. Betroeedent gout (Lat. podagra retrograda) is when, after the inflammation has occupied a joint, it suddenly disappears and is transferred to some internal part, as the stomach, heart, lungs, or brain, when it may give rise to various fatal disorders. Misplaced gout is when, instead of attacking the joints, the disease proceeds inward, and causes an inflammatory affection of some of the internal parts, with the same symptoms that attend inflamcauses an mnammatory affection or some of the inter-nal parts, with the same symptoms that attend inflam-mation of these parts from other causes. The cause of gout has been shown by Dr. Garrod to be the excess of uric acid in the blood, resulting either from an excessive formation or a checked excretion, for there is reason to believe that this substance exists in very single exaction in the blood seen in perfect health is reason to believe that this substance exists in very minute quantities in the blood even in perfect health. Topical remedies are of little use in gout. If the patient is plethoric, the inflammation is to be reduced by bleeding, purging, a low diet, and sudorifies. The use of colchicum is very beneficial during a fit of gout, but it requires to be used with caution. The great cure of this disease, however, is strict attention to diet and plenty of active exercise. The Scotch cure of "living on sixpence a day and working for it" is based upon the true nature of the disease.—Ref. Dr. Garrod On the Nature and Treatment of Gout.

GOVERMENT, and "en"-en" (Ang.-Nor.), in Pol.,

GOVERNMENT, guv'-ern-ment (Ang. Nor.), in Pol., is a word employed to denote either the particular forms under which a state is governed, the collective forms under which a state is governed, the collective body of its laws, or the person or persons in whom the supreme power is vested. There are three distinct forms of government,—a monarchy, in which the supreme power is in the hands of one person; an aristocracy, in which it is vested in a privileged minority; and a democracy, in which it is exercised either directly or indirectly by the great body of the people. Monarchy, in its abuse, becomes despotism; aristocracy tends to oligarchy; and democracy to cohlocracy, or mob government. The mixed form of government is that which combines all, or at least two, of these forms, and is an attempt to combine the good qualities of each, that which combines all, or at least two, of these forms, and is an attempt to combine the good qualities of cach, and to guard against their evil tendencies. Every government comprises within itself three distinct powers,—the legislative, judicial, and executive. In its legislative capacity, it lays down the laws by which its subjects are to be governed; its judicial power is exercised in deciding, by means of various courts and judges, all questions connected with these laws; and its executive power in carrying out or putting into execution its legislative enactments and judicial facilities. (See AUSTROMAND, DEMOGRAGY, MONARdecisions. (See ARISTOCRACY, DEMOCRACY, MONAR-

CHY, &c.) GOVERNMENT, FEDERAL. (See FEDERAL FOVERN-

MENT.)
GOVERNOE. (See STEAM-ENGINE.)
GRACE, graise (Lat. gratia, Gr. charis), is a term frequently used in Scripture, and by theological writers. In its most general signification, it is employed to denote the love and favour of God, towards mankind, more particularly in his sending his son Christ Jesus to die for sinners. It implies that the git springs from the bounty and liberality of the giver, without any claim or merit on the part of the

# Grace, Days of

recipients. It is also employed to designate the in-fluence of the Divine Spirit upon the mind, by which an individual is brought to receive the truths of Christianity; and hence, when an individual has been brought into that condition, he is said to be in a state of grace. It is also used to signify the gospel dispensation, as dis-tinguished from the legal; as when the apostle Paul speaks of our being "no longer under the law, but under grace." Some theologians assert that there are under grace. Some theologians assert that there are two kinds of grace,—common and special. Common grace they regard as being extended unto all men; special grace as that which is extended only to the special grace as that which is extended only to the clect, and by means of which they are brought unto Christ. Some speak of grace as being irresistible, efficacious, electing, justifying, sanctifying, &c. The nature of grace has been one of the most fruitful sources of controversy in the Church, gaving rise to much bitterness of feeling, and introducing many hair-splitting distinctions, for which there are no grounds in Scaintrea. in Scripture.

GRACE, DAYS OF, in Com., are certain days allowed by custom to be added to the time when a bill becomes due. The number of days varies in different countries: here it is three. Thus a hill drawn on the 7th of January, payable three months after date, is not due till the 10th of April. (See BILL OF EXCHANGE.)

GEACULLARIA, or PLOCARIA, gra-sil-lai'-re-a, in Bot., a species of plants belonging to the nat. ord. Alga, or Sea-weeds. The Gracillaria lichenoides is our com-Sea-weens. The Gracularia accessions is our commercial Ceylon moss. It is nutritive, emollient, and demulent, and may be employed in the form of a decoction or jelly as a food for children and invalids; and medicinally in pulmonary complaints, diarrhos, &c. It is sometimes imported under the name of agar-agar, but Gracillaria spinosa has also been imported under the same name. Both species are largely used in the East for making nutritious jellies, for stiffening purposes, and for varnishing. Gracillaria stiffening purposes, and for varnishing. Gracillaria Helmintho-corton is Corsican moss. It has been used principally as a verminge, but its properties have been much overrated. Gracillaria crassa, or Ki-tsai, is cooked with soy or vinegar in China; and is also used by the Chinace leding for gring and car the thickering. by the Chinese ladies for giving a gloss to theirhair.

Guacioso, grath-e-o'-so (Sp.), is the name given in Spain to the buffoon, who is a very popular personage

Spain to the buffoon, who is a very popular personage on the stage in that country.

GRADINK, grait-de-ent (Lat. gradus, a step), a term applied to the proportionate ascent or descent on any portion of a line of railway; thus an inclined plane four miles long, with a total fall of 84 feef; is said to have a gradient of 21 feet in the mile. In all cases it is desirable in constructing railways to make the road as straight, and with as near an approach to a dead level, as possible. During the early days of railwad-making more importance was attached to this subject than is exhibited now. As late as 1846 Mr. Locke had great difficulty in persuading the French authorities to tolerate inclines with a gradient of 1 in 126. In this country, however, on the Birmingham and Gloucester line, the Tickey incline, with a gradient of 1 in 37, has been for years in successful work; and on the Vienna the inclines are somethines carried been for years in successful work; and on the Vienna and Trieste railway the inclines are sometimes carried for great distances at a gradient of 1 in 40. Steep melines always, however, constitute a heavy burden on the working expenses of a railway, and should never be

the working expenses of a railway, and should never be admitted unless shoultely necessary. (See Railwax.) GRADUAI, grād'-s-āl (Lat., from gradus, a step), in the liturgy of the Roman Catholic church, is applied to the few verses of the Holy Scriptures, generally the Psalms, which are chanted after the reading of the Epistle, in the service of the Mass. It is so called from the priest, during the time, being on the steps of the alter.

The altar, grad'-u-ait (Lat. gradus, a step), is one who has taken a degree at a college or university. The act of conferring degrees is called graduation. (See

DEGREE, UNIVERSITY.)

Gradus and Parmassum, gravi-due and par-nus-aum (Lat., a step to Parmassus), is the name of a class-book used by scholars for assisting them in the composition of Latin verses. The words are arranged in alphabetical order, and the quantities of each marked. The first work of this kind was by the Jesuit Aler, and published at Cologne, 1702.

## Grafting

GRAF, graf (Ger.), a title of nobility which corresponds in Germany with our English count. The first mention of this particular grade of nobility occurs in the 5th century. There are two classes of grafs in Germany at the present time, the first forming a section of the highest and oldest nobility, and the second representing the higher order of the lower nobles.

GRAFFITO, graf, fe<sup>-to</sup> (Ital, a scratching), is the name given to a class of inscriptions which have been found in certain ancient cities, and which have recently excited some interest. They are street scribblings, the names, words, and sentences which are found rudely traced in charcoal or red chalk, or scratching the still so the plactor of the well as will are the with a stylus on the plaster of the walls or pillars in the public places. Many curious and interesting gleanings of them, found at Pompeii and elsewhere, have been made public, and more than one eminent scholar has applied himself to the subject as a special They are not only extremely curious in themstudy. They are not only extremely curious in themselves, but are valuable as tending to throw light on the every-day life and manners of the ancient world. The subjects of this wall literature of the ancients appear to have been very miscellaneous. Many of the inscriptions are of a religious character, others political; but the great majority of them appear to have been personal, and often of a satirical or grossly libellous character. Very many, indeed, hardly admit of any regular classification, being, as might be anticipated of a most mother character. Some are scrapa pated, of a most motley character. Some are scraps of poetry from well-known authors; others are doggrel verses, or short sentences of unknown origin. Some are expressions of affection for a friend, while others denote disapprobation. Many of them, too, are mere ribaldry, sometimes of the grossest and most disgusting tendency. The literary value of the graffiti is, as was to be expected, very slender; but they are interesting as throwing light upon the manners, customs, and modes of thought of the people. A small selection of these writings was published by Dr. C. Wordsworth in 1837; but the most elaborate and interesting work on this subject is the "Graffiti di Pompei," 1856. But by far the most comprehensive and magnificent work on this subject will be, when completed, "Monuments Epigraphica Pompeiana," by Jos, Fiorelli.—Ref. Edinburgh Ecview, October, 1859. are expressions of affection for a friend, while others 1859.

1859.

GRAPTING, grift'-ing (Ang.-Nor.), is a mode of propagating plants which is applicable to most kinds of trees and shrubs, with the exception of heaths and herbaceous vegetables, which do not so easily admit of the operation. It is principally directed towards fruittrees, in order to continue their varieties. A tree which is grafted consists of two separate parts,—the scion and the stock: the union of these two constitutes the graft, and the operation by which the union is effected is termed grafting. According to Loudon, the end of grafting consists—Firstly, in preserving and multiplying varieties of fruit-trees endowed, accidentally or otherwise, with particular qualities, which canmultiplying varieties of fruit-trees endowed, accidentally or otherwise, with particular qualities, which cannot be transferred to their offspring by seeds, and which would be multiplied too slowly or ineffectually by any other mode of propagation; secondly, to accelerate the fructification of trees, barren as well as fruit-bearing; thirdly, to improve the quality of fruits; fourthly, to perpetuate varieties of ornamental trees or shrubs; and lastly, to change the species of fruit on any one tree, and to renew its fruitfulness. Whip, splice, or tongue-grafting, is the mode most generally adopted in nurseries for propagating fruit-trees. It is necessary, in order to perform this correctly, that the top of the stock and the extremity of the scion should be of could diameter. The scion and stock are out off be of equal diameter. The scion and stock are out off be of equal diameter. The scion and stock are out off cobliquely at corresponding angles, or as near the same as the operator can guess; a sit is then made in the sloped face of the stock downwards, and in the scion inwards; the tongue, thus constructed, of the scion is then inserted in the cleft of the stock, the inner barks of both being made to unite closely, and the whole is then bound round tightly with base riband from left to right. The next thing to be done is to clay all round, over the bass, from about an inch below the graft to an inch above, closing up all the apertures, so that no light, wet, or wind, can penetrate; for which object the clay is applied. Cleft-grafting is another variety, and only differs from the above method in the

scion being shaped like a wedge, and being inserted in a corresponding savity in the stack. Budding is another method of grafting by means of the germs or eyes of plants, and it consists in taking an eye or bud attached to a portion of the bark and transporting it to a similar position in another or different ligneous vegetable. The only difference between budding and grafting is in the fact of the scion being in an embryo state instead of being fully grown.—Ref. Loudon's Encyclopadia of Gardening. (See also Gardening, Horneuturues, &C.)

Encyclopadia of Gardening. (See also GARDENING, HORECULFURE, &c.)
GRAIN, grain (Fr. grain, Lat. granum), the smallest weight in the systems commonly used in England and America for denoting the weights of hodies. The value of the grain is set forth in the act of parliament, 5 Geo. IV. c. 74. (See Ayolkdurols.) The grain can 5 Geo. IV. c. 74. (See Ayotanurots.) The grain can be taken as the common unit in comparing the systems of weight known as avoirdupois, apothecaries, and troy. The onnee avoirdupois contains 4375 grains. the apothecaries' and the troy onnee 480 grains. The principal terms of the decimal system of weights may thus be expressed in grains:—

-		Grains.
1	Kilogramme =	15434
1	Gramme =	15 4346
1	Centigramme =	1543
	Milligramme =	0154

A proposition for altering the value of the grain in the British Pharmacopoia was advanced in 1862; but the General Medical Council, after much consideration, determined not to interfere with the well-known weight.

weight.
Grain Tin. (See Tin.)
Grains of Paradier. (See Amomum.)
Grains of Paradier. (See Amomum.)
Grains. Grains. Grail-to-grail-to-freez (Lat.
grailes, stiles), the wading birds, the fourth of the
six orders into which Linneus divided the class Area,
or Birds. The order is thus described by him:—Bill
sub-cylindrical and rather obtuse; tongue entire,
fleshy; feet wading, the thighs half-naked; body
compressed; the skin very thin and sapid; the tail
short. Their food consists of flahes, water reptiles,
and enimalcules obtained in marshes, and their nests and animal cules obtained in marshes, and their nests are generally found near the ground. The families of the order are the Gruide, or cranes; the Ardeida, or the Total the Critical of the American of the American the Scolopacidae, or sandpipers, and snipes; the Rullidæ, or rails; the Charadriadæ, or plovers; and the Tautalidæ, or bices. It comprises all those birds which live both on land and sea, and to which both elements are essential. Those which are essentially aquatic have a short web to their toos; their wings are long, and, having no settled district, they fly from one shore and, naving no section district, they my from one shore to another as the seasons change. Several fossil remains of the families of this order of birds have been found. In the Paris basin, bones of birds referable to the genera Scolopax, Trings, and Ibis, have been found, and in the fresh-water formation of Tilgate Forest, the remains of a wader larger than a heron were found by Dr. Mantell. The fossil footsteps of wading birds, observed by Professor Hitchcock, in the new red sandstone valley of the Connecticut, show that formerly at least seven species of Grallatores existed, varying in

least seven species of Grallatores existed, varying in size from that of a snipe to twice that of an ostrich.—

Grammacze. grām-in-ai-se-e (from Lat. gramen, grass), in Bot., the Grasses, a nat. ord. of Monocotyle-dones, sub-class Glumaczes. Of all the orders in the vegetable kingdom, this is the most important to man, as it affords his principal food, and is eminently serviceable in other respects, by supplying fodder for cattle, sugar, and numerous useful products. As a botanical group, there is none more natural, for the tariations observed in the herbs, shrubs, and arhores. variations observed in the herbs, shrubs, and arbores-cent plants composing it, are of the simplest kind, arising generally from differences in the proportions of parts. The stem of a grass is round, jointed, and comparts. The stem of a grass is round, jointed, and commonly hollow. The leaves are alternate, with split sheaths, terminating above in membranous tongaes or ligules. The flowers are perfect, or unisexual, and grow in bunches (locuste or epikelets), or aingly. There is no true perianth, its place being supplied by imbricated braots (the chaff-scales), of which there are commonly two, called glumes (see first illustration, b, b), placed at the base of the solitary flower, or at the

base of each locusta; rarely, there is only use glume. Occasionally these envelopes are altogether absent. Each flower is also usually furnished with two additional alternate bracts, called pales (a, a, in first flustration); sometimes the inner pales is wanting. There are also, in some cases, two or three scales, called locations, or glumellules, present. The stamens vary in number from one to six, or even more—the number is frequently three (see second illustration e, c, c) the filaments are capillary; the antiers versatile. The overy (a) is superior and one-celled, with a solitary

FLOWER OF THE OAT.

ascending ovule; the stigmas (b,b) are feathery, or hairy. The fruit is a caryopsis. The seed has mealy albumen and a lenticular embryo, lying on one side at the base of the albumen. The form of inflorescence is a point of great importance in the classification of the grasses. The single flowers, or locusts of flowers, may be arranged on a central column (rachis), so as to form a compact head or spike (as in wheat); or they may be placed on a more or less branched axis, so as to form a penicle (as in the oat). Grasses are universally may be placed on a more or less branched axis, so as to form a paniele (as in the oat). Grasses are universally distributed over the globe. In temperate and cold-climates they are herbaceous, and of moderate height, while in tropical climates they become shrubby and arborescent, and sometimes grow to the height of fifty or sixty feet. Grasses usually grow together in large masses, and thus form the vardure of great tracts of soil: hence they have been termed social plants. There soil: hence they have been termed social plants. There are 300 genera and probably about 3,800 species. The most important genera are Triticum, wheat; Hordeum, barley; Anena, oat; Orgua, rice; Zea, Indian corn, ornsize; Secale, rye; Panicum, millet; Saccharum, sigar-cane; Bumbusa, bamboo; Andropogon dactylis, and Holcus. (See these names.)
GRAMMAN, Gram-matike, Lat. grammatica), is the art of grammatic or writing any language with correctness and

speaking or writing say language with correctness and propriety. Considered as an art, it necessarily supposes the previous existence of a language, the object of which is to communicate thought. Without attempting any alteration in a language already in use, it forms to be considered to the control of th it furnishes certain rules, founded on observation, to which the method of speaking adopted in that language may be reduced; and this collection of rules is called may be reduced; and this collection of rules is called the grammar of that language. But apart from gram-mar, as applied to any particular language, there is the pure science of grammar, otherwise called universal grammar, which views language only as significant of thought, and, neglecting particular and arbitrary modi-fications, introduced for the sake of beauty, or other-wise, examines the analogy and relations between words and ideas. Adsiryariable, between those narticulars and ideas; distinguishes between those particulars which are essential to language and those which are only accidental; and thus furnishes a certain standard only scoidental; and thus furnishes a certain standard by which different languages may be compared, and their several excellencies or defects pointed out. "Grammar," says Max Müller, "owes its origin, like all other sciences, to a very natural and practical yant. The first practical grammarian was the first practical grammary and the beginnings of the science of language, we must try to find out at what time in the history of the world, and under what circumstances, people first thought of learning any language besides their own. At that time we shall find the first practical grammar, and not till them. Much may have been ready at hand, through the less discreted, researches of philosophers, and likewise through the critical studies of the acholars of Alexandria, on the ancient forms of their language, as preserved in the Homeric poems. But rules of declension and conjugation, paradigms of regular and irregular nouns and verbs, observations on syntax, and the like; these are the work of the teachers of languages, and of no one else." Grammar, therefore, is of comparatively modern origin. No ancient Greek ever thought of learning a foreign language. It was through the study of the annient dialects of their own language that the Greeks of Alexandria were first led to critical and philological studies. The general outline of grammar existed at an earlier period, but they were the first to study the language critically, analyzing and arranging it under general eategories, distinguishing the various parts of speech, inventing proper technical terms for the various functions of words, &c. The first real practical Greek grammar was that of Dionysius Thrax, a Thracian, who went to Rome, and taught the language there about the time of Pompey. He was the first who applied the results of the labours of former philosophers and critics to the practical work of teaching. His work thus became one of the principal channels through which from Athens to Alexandria flowed back to Rome, to spread from thence over the whole civilized world. We can follow the stream of grammatical science." spread from thence over the whole civilized world. "We can follow the stream of grammatical science," says Müller, "from Dionysius Thrax to our own time in an almost uninterrupted chain of Greek and Roman writers. We find M. Verrius Flaccus, the tutor of the grandsons of Augustus, and Quintilian, in the first century. Scenurs. Application. Dysochus, and his son century; Scaurus, Apollonius Dyscolus, and his son Herodianus, in the second; Probus and Donatus, the teacher of St. Jerome, in the fourth. After Constantine had moved the seat of government from Rome, grammatical acience received a new home in the academy of Constantinople. There were no less than twenty Greek and Latin grammarians who held professorships at Constantinople. Under Justinian, in the sixth century, the name of Priscianus gave a new lustre to grammatical studies, and his work remained an authority during the middle ages to nearly our own times. We ourselves have been taught grammar according to the plan which was followed by Dionysius at Rome, by Priscianus at Coustantinople, by Alcuin at York; and whatever may, be said of the improvements introduced into our system of education, the Greek and Latin grammars used at our public tine had moved the seat of government from Rome, the Greek and Latin grammars used at our public schools are mainly founded on the first empirical analysis of language prepared by the philosophers of Athens, applied by the scholars of Alexandria, and transferred to the practical purpose of teaching a foreign tongue by the Greek professors at Rome."— (Lectures on the Science of Language, 3rd edition, 1862.)
It is in the grammar of a language that we can trace its distinctive features. The English language, for instance, is made up of words borrowed from almost its distinctive features. The English language, for instance, is made up of words borrowed from almost every country of the globe.—Latin, Greck, Hebrew, Celtic, Saxon, Danish, French, Spanish, Italian, German—nay, even Hindusthin, Malay, and Chinese words, lie mixed together in the English distincary; but not a single drop of foreign blood has entered into the organic system of the English language. "The grammar, the blood and soul of the language, is as pure and unmixed in English as spaken in the British isles as it was when spoken on the shores of the German Ocean by the Angles, Saxons, and Jutes of the continent." Grammar is, after all, but decleasion and conjugation. Originally, decleasion could not have been anything but the composition of a noun with some other word expressive of number and case. The like holds true with regard to verbs, though it may seem difficult to discover in the personal terminations of the Greek and Latin the crast-pronouns which were added to the root of the verb in order to express, I love, thou lovest, he loves. It stands to reason, however, that originally these terminations must have been the same in all languages; namely, personal pronouns. "It is very likely," says the author already so frequently quoted, "that the gradual disappearance of irregular decleasions and conjugations is due in literary, as well as in illiterate languages to the dialect of children. The language of children is more regular than our own. I have heard children is more regular than our own. I have heard children is more regular than our own. I worse and worst. In treating of the grammar of any grammar.

language, grammarians usually divide the subject into four distinct heads:—Orthography, or the art of combining letters into syllables and syllables into words; Brymology, or the set of deducing one word from another, and the various modifications by which the sense of any one word can be diversified consistently with its original meaning, or its relation to the theme whence it is derived; Syntax, or what relates to the construction or due disposition of the words of a language into sentences or phrases; and Prosody, or that which treats of the quantities and acceuts of syllables, and the art of making verses. All language is made up of words, which may be defined to be sounds signifrom to fosme idea or relation, and may be distin-guished as—1. Substantives; 2. Attributives; 3. Defini-tives; and 4. Connectives. Substantives are words expressive of things which exist, or are conceived to exist, of themselves, and not as the energies or qualiexist, of themselves, and not as the energies or quanties of anything else. They are noins and pronouns, the latter being a species of word invented to supply the place of nouns in certain circumstances. They admit of the accidents of gender, number, and case. Attributives are words that are expressive of all such things are reconciling to exist not of themselves, but things as are conceived to exist not of themselves, but as the attributes of other things. They are verbs, participles, adjectives, and adverbs. The attributes expressed by verbs have their essence in motion or its expressed by veros have their essence in motion or its privation; and as motion is always accompanied by time, therefore verbs are liable to certain variations called tenes. To denote the several kinds of affirmation expressed by verbs, all verbs have what are termed moods or modes; as the indicative, I write; subjunctive, I may or can write; imperative, write thou. Verbs are also distinguished as active-transitive when the action denoted by them passes from the actor to some external object; active intransitive, when no such passing takes place; passive, such as express not action, but passion or suffering; and neuter, such as express an attribute that consists neither in action nor in passion. Participles are such words as express an attrisuch ratterpes are such words as express an attri-bute combined with time; as, erriting, written. Adjec-tives express, as inhering in their substantives, the several qualities of things of which the essence con-sists not in motion or its privation; as, good, bad, proper. Some qualities are of a such a nature that one substance Some qualities are of a such a nature that one substance may have them in a greater degree than another; and therefore adjectives denoting these qualities admit, in most languages, of variations called degrees of comparison. Adverbs, from being attributes of attributes, have been called attributives of the second order, to distinguish them from verbs, participles, and adjectives, which denote the attributes of substantives, and are therefore called attributives of the first order. Adverbs are of two kinds whose which are converand are therefore cannot attributives of the inst order. Adverbs are of two kinds,—those which are common to all attributives of the first order, i. e., which coalesce equally with verbs, participles, and adjectives, and those which are confined to verbs. Definitives are such words as serve to define and ascertain any particular object or objects as separated from others are such words as serve to define and ascertain any particular object or objects as separated from others of the same class. These are commonly called articles; of which there are two kinds,—the definite and the indefinite. Connectives are such words as are employed to connect other words, and of several distinct parts to make one complete whole. They are of two kinds,—conjunctions and prepositions. Conjunctions are those connectives which are commonly employed to conjoin sentences. They are of two kinds,—conjunctives, or such as conjoin sentences and their meanings too, and disjunctives, for such as, while they conjoin sentences, disjoin their meanings. Prepositions conjoin words which refuse otherwise to coulease; and this they do by signifying those relations by which the things expressed by the united words are connected in nature. Interjections are a class of words which are to be found in perhaps all languages; but they cannot be included in any of the above classes, for they are not subject to the rules and principles of grammar, as they contribute nothing to the communication of thought.—Ref. Encyclopadia Evitamina; Encyclopadia Metropolituna. (See LANGUAGE.)

Grammaria, for the contribute and contribute of honour given to persons accounted learned in any art or faculty whatsoever; but now it is commonly applied to one who is skilled in or who teaches grammar.

GRAMMS, gram (Fr.), the unit of weight in the
French metric system. At is the weight of a cubic
centimetre of distilled water at its greatest density,
that is to say, at the temperature of 41° of the centigrade thermometer. It is somewhat under 15½ grains,
its exact value in grains being expressed decimally by 15.4346. (See METRIC SYSTEM.)

\*\*Geams. (see Metric Strem.)
Grampis. (See Whale.)
Grandllas, gran-a-div-las (Sp.), the edible fruits
if certain species of passion-flower. (See Passiziona.)
Grand Coutumize of Normandy, koo-koo-a-a, is
the name of an ancient collection of the laws of Northe name of an ancient collection of the laws of Normandy, which formerly prevailed also in this country. It is said to have been compiled in the third year of Henry III. The islands of Jersey, Guernsey, Alderney, &c., which formerly belonged to Normandy, but were united to the English crown by the first princes of that line, are still governed according to the laws of le grand Contumier.

Grand Dars, in Law, are those days in the terms which are solemnly kent in the inns of court and

GRAND DAYS, in Law, are those days in the terms which are solemnly kept in the inns of court and chancery; viz., Candlemas-day in Hilary, Ascension-day in Easter, St. John Baptist's day in Trinity, and All Saints' day in Michaelmas,—all dies non juridict. GRANDER, grân-dec' (Sp. grande de España), is the name of the highest rank in the Spanish nobility. The

name of the highest rank in the Spanish nobility. The collective body of the grandees is called la grandees. To this class belonged that very powerful section of the nobility who, from their great wealth, were called the ricos hombres (rich men). The grandees were originally the descendants of the great feudatories of the crown, and were possessed of many important privileges; among which were exemption from taxation, and from the power of any civil or criminal court. and from the power of any civil or criminal court, without a special warrant from the king. They had also the right of bearing a banner, and of enlisting soldiers on their own account, and might even enter the service of a foreign prince at war with Castile without being guilty of treason. At length Cardinal Ximenes acceeded in breaking their power and dearning them. depriving them of many of their privileges. Subsequently it became the practice of the Spanish kings to raise new men to the rank of grandees, partly with the raise new men to the rains of grainees, party with the view of destroying the power of the ancient nobility, and partly to reward their friends. In this way three classes of grandees areae, differing in rank as well as in the privileges which they enjoyed. Under the government of Joseph Bonaparte the dignities and privileges of the grandees were entirely abolished, but they were partially restored at the restoration. There are very few of the old families now extant in the direct line

Grand Jury, in criminal jurisprudence, is a body of good and sufficient men, whose business it is to examine into the charges of crimes brought before examine into the charges of crimes frought before them at assizes or sessions; and if satisfied that there is sufficient cause, they return a bill of indictment against the accused, upon which he is afterwards tried by the petty jury. The sheriff of every county is bound to return to every session of the peace, and every commission of oger and terminer, and of general goal delivory, twenty-four good and lawful men of the county, to inquire, present, do, and execute all those things which, on the part of the sovereign, shall then and there be commanded them. As many as appear upon this panel are sworn upon the grand jury, to the amount of twelve at least, and not more than twentythree, so that twelve may be a majority. The grand jury are first instructed in the articles of their inquiry by a charge from the judge who presides on the bench. They then withdraw to sit and receive indictments, which are preferred to them in the name of the queen but at the suit of any private presecutor. They are only to hear evidence on behalf of the presecution, for they are only to inquire whether there be sufficient cause to eall upon the party to answer it. They ought, however, to be thoroughly persuaded of the truth of an indictment, so far as the evidence goes, and not to rest satisfied with mere probabilities. The institution of grand juries is very ancient, and can be traced back to the reign of King Ethelred. For grand jurors at assizes, no qualification by estate is necessary; at sessions, the qualification is the same as that of the petty jury. (See Jury.) cause to call upon the party to answer it. They ought 98:

## Granitic Rocks

Grand-Master, a name which was applied, during the middle ages, to the chiefs of the various dominant orders of knighthood; as the Templars and the Hospitallers, the latter of whom were later etermed the Knights of Malta. The grand-master was, in a sort of a way, the sovereign for life of the order which he sommanded, and his word was law in all matters, whether concerning life or death. Bir Walter Soott, in his romance of Ivanhoe, has given a very good sketch of how the post of grand-master was filled and abused by the men to whom it was intrusted. During the days of the ancient monarchy in France, there was an office termed the Grand-Master of France, who was an office termed the Grand-Master of France, who was chief of all the officers of the household; and later, during the empire, there were grand-masters of the ouniversities; but the term has, in the present day, to all practical purposes, exploded. Grand Serbearty (Lat. magnum servitum, great

service), in Law, was a tenure by which the tenuat was bound, instead of serving the king generally in the wars, to do some special bonorary service to him in person; as to carry his banner, his sword, or the like; person; as to carry his banner, his sword, or the like; or to be his butler, champion, or other officer at his coronation. It was of the nature of grand serjeant that it held of the king: the like tenure held of a subject was only knight-service. Tenants holding by grand serjeanty were not bound to pay aid or esouage, as was the case in knight-service. Tenure by cornage, which was to wind a horn when the Scots or other enemies entered the land, in order to warn the king's subjects, was a species of grand serjeanty. This tenure was preserved by 12 Charles II. c. 24, which abolished the other feudal tenures, and still subsists in some cases.

GHANTER, gran'-it (Lat. granum, a grain), in Min., a kind of rock, so named from its granular structure. The typical granite is a crystalline aggregate of the three minerals, felepar, mica, and quartz. The proportions of the three constituents vary indefinitely, with this limitation, that the felspar is always an essential ingredient, and never forms less than a third, rarely less than half of the mass, and generally a still rarely less than half of the mass, and generally a still larger proportion. Sometimes the mice, sometimes the quartz, becomes so minute as to be barely per-ceptible. The state of aggregation of the mass varies also greatly, some granies being very dose and fine-grained, others largely and coarsely crystalline. The grained, others largely and coarsely crystaline. The colours of the rock are generally either red, grey, or white,—the first when the felspar is flesh-coloured, the latter when it is pure white, the intermediate grey tints depending chiefly on the abundance and colour of the mica, but sometimes on that of the quartz. The hard and close-grained granite forms the most durable building-stone for heavy structures; the soft and de-composable yields the finest kaolin, or china-clay. With respect to the granites of Devonshire and Cornwall, which have always maintained a high character for exceeding durability, Sir H. de la Beche remarks : -"There is much good granite on Dartmoor, though it is not always sufficiently accessible to be carried long distances; the chief places where it is worked in large quantities and afterwards exported, are Hey or High Tor, on the east, and near King Tor on the west. The granite from the former places is conveyed by a tramroad to the Stover Canal, down which it is carried in boats, and afterwards down the Teign to Teignmouth, to be shipped for its destination. That from the west side of the Moor is conveyed by the Princestown and Plymouth tramroad to the latter place, and shipped. The continuation of the Hingston Down granite is worked up the Tamer, near New Bridge, and exported from Morwellham. A very hard variety is obtained upon the higher part of the Down, and has obtained upon the higher part of the Down, ann as been employed advantageously for pavements. The chief quarries in the eastern or hard part of the harborough mass of granite are those of the late Mr. Austin Treffry, up the Par Valley, commonly known as Lostwithiel granite. Extensive quarries are there-worked, and the stone is brought to the head of the canal near Pons-mill, upon which it is conveyed to Par Harbour, and there shipped. The Carn Meneiez mass has furnished the granite most commonly known as the Country. as the Cornish. It is nearly altogether shipped at Penryn, where it is brought variable distances from different quarries in the vicinity, many situated in the

2 T 2

#### Granitic Rocks

parish of Mabe. In London, the kerb and paving-stenes parish of Mabe. In London, the kerb and paving-stenes are obtained almost exclusively from the country of Aberdeen. In the district of Peterhead the red granite principally prevails; hence it is commonly called "Peterhead granite." The polished pillars of the Carlton Club, in Pall Mall, are of this granite. Argyleshire also affords excellent granite, and from the island of Mull, which is included in this district, a large proportion of the stone used in the construction of the ion of the stone used in the construction of the Albert Memorial in Hyde Park has been brought. The Albert Memorial in Hyde Park has been brought. The Asle of Man possesses a grey granite; and in Lundy Island, which is almost exclusively of a granitic formation, quarries of a very rich and productive kind have been recently opened. A very large quantity of the stone used in the construction of the Thames Embank. ment has been obtained from these quarries. In Ireland the counties of Wicklow, Carlow, Kilkenny, and Gal-way are occupied by a considerable area of granite. Wicklow granite is extensively used; the variety ob-tained from the neighbourhood of Kingstown being of a hard and coarse character; whilst that quarried at Golden Hill, being of a finer kind, is more used for the purposes of ornamentation.

Grantitic Rocks, grân-it'-ik, & Geol., those igneous rocks which partake of the character and appearance of granite. (See IGNEOUS ROCKS.) They are highly crystalline, and their component crystals are never rounded or water-worn; they present no traces of deposition or stratification; they occur in the earth's crust, as mountain-masses and veins, bursting through and displacing the sedimentay rocks; and they indu-rate, and otherwise alter (as all heated masses do), the rate, and otherwise atter is an inested masses to), the strata with which they come in contact. From these circumstances they are held to be of igneous origin; and as far as geologists have been able to discover, they are the most deeply-seated of all rooks, forming, as it were, the floor or foundation for all the superincumbent formation. As the earliest of the igneous rocks, they are generally found associated with pri-mary and transition strata, tilting them up on their edges, bursting through them in dykes and veins, and variously altering their positions and mineral characters.
Granitic rocks form the principal mass of the most extensive mountain-ranges in the world. The mountains of Cumberland, Devon, and Cornwall, in England, the Grampians in Scotland, the Wicklow mountains in the Grampians in Scotland, the Wicklow mountains in Ireland, the Dofrafelds in Scandinavis, the Alps in Switzerland, the Pyrenees in Spain, the Oural and Himalayan ranges in Asia, the Abyasinian and other ranges in Northern Africa, the hills of Damara and Namqua Land in Southern Africa, the central range of the island of Madagascar, and the Andes in South or the island of Madagascar, and the Andes in South America, are all less or more composed of granitic rocks, or of primary strats, thrown up and altered in mineral character by these granitic intrusions. 'Until recently it was an opinion almost universal among geologists that granite had been formed by igneous fusion, and had solidified from a molten condition under enormous pressure, the theory being supported partly by the crystalline and unstratified character of the rock, but chiefly by the fact that almost every large mass of granite gives off numerous ramifications, or veins, which penetrate the surrounding rocks, and which appear to have been formed by injection of the molten granite into neighbouring fissures. Evidence has, however, accumulated during the last few years, tending to modify this theory very materially. Thus, it has been found that the specific gravity of quarts which has undergone fusion is never higher than 2.3, which has undergone tusion is never higher than 2's, whilst that of the quarts in granite reaches 2's, a fact sufficient in itself to oppose the igneous theory, were it not that the pressure under which granite has evidently been formed must, as Dr. Haughton has pointed out, very considerably increase the density of the silfae. Again, many minerals occurring in granite, either as essential or as accessory constituents, are such as could not have existed at a high temperature; come of them indeed annia as certain varieties of some of them, indeed, such as certain varieties of mics, containing a notable proportion of water. Many of these minerals, moreover, are so highly basic, that it is difficult to understand how they could have been fused in the presence of free quartz without entering into differential combination with the silica. Finally, the constituent materials of granite have, in most cases, not solidified in the order of their relative

# Graphotype

infusibility; the quartz, which is the most infusible, having evidently solidified last, gince it commonly bears the impress of the felspar crystals."—Reference, Ure's Dictionary of Arts, Manufactures, and Mines—Sixth edition; Page's Advanced Text-Book of Geology.

Geology.

Grant, ordat (Nor. granter, to. grant; Lat. concessio), in Law, is strictly a conveyance in writing of incorporeal hereditaments, or of things of which no livery can be had; for all corporeal hereditaments, as lands and houses, were said to lie in livery, and the others, as advowsons, commons, rents, reversions, &c., to lie in grant. The latter, therefore, pass merely by delivery of the deed. By 8 & 9 Vict. c. 106, it is enacted that estates, corporeal as well as incorporeal, may be conveyed by grant; by which means the conveyance of corporeal hereditaments is much simplified. plified.

GRANULATION, gran-u-lai-shum (Lat. granulatio, from granum, a grain), in Surg., is the name given to that process by which small grain-like fleshy bodies form upon the surface of theers and suppurating wounds, and serve for filling up their cavities, and bringing nearer together and uniting their sides. This process is also sometimes called incarnation (from Lat. area commit flesh). Sometimes in weak or un Lat. caro, carnie, flesh). Sometimes, in weak or un-Lat. caro, carms, Hesh). Sometimes, in weak or unhealthy constitutions, granulation proceeds very slowly; at other times it is excessive, rising above the level of the surrounding skin, without showing any disposition to heal, but forming what is popularly termed proud flesh. (See Wounds, Ulcars.) Granulation, in Metal, a process resorted to to obtain metals in a coarse state of division. The metal is melted in a cruisile and noured into water from

is melted in a crucible, and poured into water from the height of three or four feet.

the neight of three or lour leet. Geares. (See VITIS.)
GRAPES. HOT, graip, a kind of shot used against troops advancing in column at a short distance, or, in naval warfare, to sweep the decks of an enemy's ship nava warrare, to sweep the decks or an enemy's snip at close quarters. It consists of a number of balls fastened together, in the form of a short cylinder. The balls wary from ball a pound to four pounds in weight, according to the calibre of the piece from which they are to be discharged. Grape-shot was formerly made by putting the balls into a canvas bag, which was secured to an iron plate, equal in diameter to the calibre of the gun, and having a pin passing through its centre and the bag of shot, about which the balls were secured by cord. This gave the shot in through its centre and the bag of shot, about which the balls were secured by cord. This gave the shot in some measure the appearance of a bunch of grapes; whence its name. The shot are now placed between a series of it on plates, the whole being kept together by pressure, exerted by a nut screwed on to the end of the bolt which passes through them.

General General, graff-ik (Gr. grapho, I write), in Min., a species of granite having the appearance of being covered with letters of an Oriental character, owing to the angular arrangement of the quartz or

felspar it contains.

foispart contains.

Gazerize, grd/~ite (Gr. grapho, I write), is black-lead, a mineral consisting of nearly pure carbon, found in Cumberland, Ceylon, Siberia, Canada, Brazil, and other parts of the world. It occurs in prisand other parts of the world. It occurs in pris-matic masses with a transverse foliated structure, also granular and compact. The finest quality is found at Borrowdale, in Cumberland. It is nearly pure carbon, and is perfectly free from grit. It is used principally in the manufacture of lead-pencils. The coarser quality is used, when ground, for polishing iron-work, for glazing gunpowder, as a lubricator for machinery, and in the manufacture of black-lead melting-pots. (See BLACK-LEAD, PLUMBIGO.) It is used for the lat-ter purpose on account of its unalterability by heat. It is formed artificially during the fusing of cast-iron containing large quantities of carbon. It dissolves in the molten iron, re-crystallizing as it cools, and being often thrown off from the surface of the iron in scales. Professor Brodie, of Oxford, has devised a plan by which the coarsest graphite may be purified. He heats the powdered mineral with sulphuric acid and chlorate of potash, which causes it to exfoliate in an extraordinary manner; a little fluoride of sodium dissolves the silicious impurities, and the whole is well washed in

GEAPHOTYPE, gra'-fo-tipe (Gr. grapho, I write; tupos,

an impression), the name given to rew process of engraving, discovered in 1860 by Mr. de Witt Clinton Hitchcock, an artist of New York. It is a process which enables the artist to become his own engraver. which enables the artist to become his own engraver. Mr. Hitchcock, in a piaper read by him before a meeting of the Society of Arts, describes the incident which led to the invention. Mr. Hitchcock, in the course of making a drawing on boxwood, found it necessary to alter a portion of his design by erasing and re-whitening the exposed surface of the wood. The material used for this purpose was the enamelled surface of an ordinary visiting-card, softened by water and a brush,—a method known to draughtsmen on wood. The card employed happened to be one printed from a copper-plate, and after the removal of all the enameling as described, the artist discovered that the printed ing as described, the artist discovered that the printed letters were undisturbed and standing up in bold relief. In order to carry out the idea which this circumstance suggested, he prepared a slab of chalk, one side of which was made smooth by scraping; upon this smoothed surface he drew with a quilt pen, thing as ink silicate of potash coloured with indige. When the lines of the design became dry he brushed away with a tooth-brush—using no water—all the portions of the chalk surface upon which there were no lines. The lines of the drawing, being literally composed of stone, withstood the action of the tooth-brush, but the intervening portions of chalk gave way and vanished in a cloud of snowy dust, leaving the lines of the drawing standing in bold whief. In order that this design might be printed on paper, it was necessary to harden the block upon which the drawing stood. This was done by saturating the chalk mass with the liquid silicate of potash, or "water-glass." In half an hour the block was printed from in the ordinary way. The process has been improved and elaborated as the reprocess has been improved and elaborated as the result of a great number of experiments, and at the present time it is conducted as follows:—"An artificial chalk block or plate is first produced by grinding the best French chalk to a fine powder with water to a thin cream, and separating the portion which precipitates first, repeating the operation several times in order to insure the complete separation of any hard or coarse particles, drying the very finely-divided chalk thus obtained, and sifting it through wire-cloth having 10,000 holes to the square inch, on to the surhaving 10,000 holes to the square inch, on to the surface of a perfectly smooth plate of zinc, placing a plate of highly polished steel on the top of the even layer of chalk-flour thus obtained, and then submitting it to powerful hydraulic pressure. On removing the pressure and lifting off the steel plate, the chalk is found to be firmly attached to the zinc plate, and to present a perfectly smooth upper surface, which only requires to be 'sized' in order that the ink to be used in drawing on it may not 'spread,' to be ready for the artist. The latter proceeds as in the ordinary method of drawing on wood, first making a red chalk tracing on the block or plate, and then with sable-hair method of grawing on wood, arist making a red chair tracing on the block or plate, and then with sable-hair pencils of various sizes, drawing his design line for line exactly as he wishes it to appear when printed. The ink used is a mixture of glue and lampblack, and The link used is a mixture of kine and manpolack, and dries instantly; so that one series of lines, of whatever thickness, may be immediately crossed by others. The drawing being completed, the portions of the chalk surface intervening between the lines of the drawing, surface intervening netween the lines of the drawing, are disintegrated and removed, to the depth of an eighth of an inch or so by means of brushes, some of them of fitch-hair and others of silk velvet, and the chalk blook is then hardened by being scaked in a solution of an alkaline silicate. A mould is then taken

thrown into the rigging of the hostile ship, in order to fasten the two together, so that the boarding party may rush on the decks of the enemy from their own

GRASSES. (See GRAMINACEE.)

GRASSHOPPER, grass-hop-per, a species of insect common in the British islands and in foreign countries, which belongs to the general family of the Gryllide, which latter come under the class of Orthoptera, and its sub-section Saltatoria, or jumpers. The grasshoppers, like other Gryllide, are characterized by their legs and sub-section Saltatoria, or jumpers. The grassnoppers, like other Gryllides, are characterized by their legs and antennse being very long and slender, the wings large and delicate, and the wing-covers often extending far beyond the extremity of the abdomen. In the male insects these wing-covers are furnished at the base, near the suture, with a round tail-like plate, surrounded by strong ridge-like bands; and the chirping noise peculiar to the family is produced by rubbing the cases of the wing-covers shurply over each other, these ridges serving the purpose of a sort of drum. The common great green grasshopper of this country (Phasgomera Gryllus viridissima) is one of the largest of our naive insects, and measures about two inches in length and three and a half in the expansion of its wings. The field-cricket, or Gryllus compestine of Linnaus, is another species of grasshopper; it is of a black colour, and a little larger than the house-cricket; it frequents dry sandy districts, where it burrows in the ground. The female of this latter insect is said to lay upwards of 300 eggs.

Grass-colls. (See Andropogon.)

to lay upwards of now eight.

GRASS-CILS. (See ANDEOFOGON.)

GRASS-TRIES. (See XANTROBEREE.)

GRASSUM, grid-sum, in Ecots law, is the gross rent
paid in anticipation of possession for a series of years.

This transaction is valid with singular successors where This transaction is valid with angular successors where the yearly rent payable over and above the grassum is not clusory. An heir of entail, prohibited from diminishing the rental, may take grassum, provided the former rent may be continued; but if prohibited against letting below a just rent, grassum is excluded. GRATIOLA, prå.she-o-id (Lat. grasse of God, by Mattitle). The property of the part ord

having been named Gratia Dei, grace of God, by Matthiolus), the Hedge-hyssop, a gen. of the nat. ord. Scrophulariacea. The species G. officinalis possesses purgative, emetic, and directic properties, and was formerly employed in medicine. Its properties are due to the presence of an acrid poison.

GRATLITOUS DEEDS, gratule-stus (Lat. gratuius, free, voluntary), in Law, are instruments made without binding or equivalent considerations.

GRAVEL, (See CLEGUES).

GRAVEL. (See CALCULUS.)

GRAVEL. (See CALCULUS.)
GRAVEL, grav-et (Fr. gravelle), the familiar as well as technical term for accumulations of water-worn rock-fragments, where the pebbles vary from the size of a pen to that of a hen's egg. Accumulations of incr detritus are known as sands, and those of fragments larger than an egg as shingle.
GRAVITATION, grav-i-tait-shau (Lat. gravis, heavy), is a term nearly synonymous with gravity,—which is applied to denote that tendency which all bodies in nature have more or less to approach each other. This force of gravitation varies directly as the masses of the bodies, and is inversely proportional to the of the bodies, and is inversely proportional to the squares of their distances apart from each other. Every particle of matter in the universe has an inclination to assimilate with other particles, and to press inwards; and this is a fact which is proved by eighth of an inch or so by means of brushes, some of them of fitch-hair and others of silk velvet, and the of halk block is then hardened by being soaked in a solution of an alkaline silicate. A mould is then taken from the chalk tlock, and a type-metal cast produced from this mould, and by the ordinary processes of from this mould, and by the ordinary processes of streetyping, and it is the type-metal cast, and not the original block, that is used to print from."—(Mechanica' Magazine.) A type-metal cast may be obtained within three hours after the completion of the drawing upon the chalk surface. This cheap and expeditious process possesses many advantages over wood-engraving, which is a costly and an expensive method.

Gerrel (Fr. grappin), a sort of small anchor with four or five flukes, or arms, used in boats and small vessels and in balloons. Grappels, or grapinging-irons, are likewise brought into action in boarding vessels during marine combats, when they are

#### Gravitation

rentre of the earth. Newton also adds, that as the total force which solicits any given molecule, being the sum of the actions of sach molecule of the attracting body, its intensity will be proportional to the number of molecules contained in the latter. For example, if we suppose that the earth, without undergoing any alteration of its dimensions, were to become more compact by a hundredth part, or, in other words, that within the same volume it contained a hundredth part more matter, then the attractive force which it would more matter; then, the attractive force which it would more matter; then, the attractive force which it would be in-creased a bundredth part. All bodies must necessarily move towards, or in the direction of, the centre of the earth, by the effects of this gravitation, as a sphero always attracts an exterior body in a manner as if all its matter were condensed into a single point at its its matter were concensed into a single point at its centre. From the sxiom that all bodies, when deprived of support, fall from any height to which they may have been clevated, it may be justly inferred that gravity acts upon them during the whole time occupied in their descent with a uniformly accelerating force, which may be proved from the fact, that bodies which fall from a greater height than others arrive at the fall from a greater height than others arrive at the tail from a greater height than others arrive at the earth with a proportionably greater velocity. Galileo was the first who established the fast that the acceleration of all falling bodies is uniform; and he deduced the corollary that the spaces descended through are as the squares of the times of descent. He likewise proved that terrestrial gravity acts equally on all bodies, or, in other words, impresses on all of them an equal quantity of motion, whatever their nature may be. In order to demonstrate this Galileo had several be. In order to demonstrate this, Galileo had several sollow spheres constructed of equal weight and diameter, and in these he inclosed equal weights, formed, however, of different substances; the spheres were then suspended by strings of equal length, and made to vibrate in small ares with a pendulum movement; and it was found the time occupied in describing the are, or the oscillation of each, was equal in all. This may not be clear to all, as light bodies—such as feamay not be clear to all, as light bodies—such as feathers and paper—fall more slowly to the ground than a piece of metal. But it must be remembered that this is due, not to the inequality of the attraction of gravitation, but to the buoyancy of the attraction of gravitation, but to the buoyancy of the attraction of gravitation, but to the buoyancy of the attraction of gravitation, but to the buoyancy of the attraction is properly as in the exhausted receiver of an airpump a feather and a piece of gold, if let fall from the top, will reach the bottom at the same, time, and will descend with perfectly equal speed. That attraction is proportional to the mass, may be shown by the following induction. The variation of a mass, or the attractive force of the earth, becomes apparent by a corresponding variation in the velocity of the falling body. This velocity, which for a short space of time must be supposed uniform, will, in effect, be proportional to the force which generates it. As the force must be supposed uniform, will, in effect, be proportional to the force which generates it. As the force is proportional to the mass, it follows, therefore, that the velocity will also be proportional to that body. In the present day a body in the latitude of Paris falls through 16 1 the feet during the first second of its descent. But if the earth's mass were increased by a hundredth part, as stated before, the space described by the falling body during the first second of time would also be increased in the same proportion, and the valocity, instead of being measured by 16 09 feet, would be expressed by the sum of 10 09 plus 0 16 feet, would be expressed by the sum of 10 09 plus 0 16 feet, or 16 25 feet. The space through which a body falls in or 16:25 feet. The space through which a body falls in one second of time, from the action of gravity, diminishes as the height above the earth's surface increases, is no as the legal above the sain a surface increases, and on the top of a high mountain it is sensibly less than at the level of the sea. The force which generates this velocity, or the attractive force inherent in the molecules of matter, diminishes, therefore, as the distance increases. With regard to the measurements by which scientific men have been enabled to exemplify which scientific men have been enabled to exemplify the principlen of terrestrial gravitation, it must be determined how and what velocity is imparted to a body falling freely in a given time. First, in order to show that gravity is a uniformly accelerating force, Attwood's machine is the best experimental method by which the proof can be deduced. This apparatus consists of a pulley, having a groove on its edge to receive a silken cord which passes over it, and the arrest turns on friction-rollers no as to obtain any stormage turns on friction-rollers, so as to obviate any stoppage in its rotation. To fach end of the string which passes over the pulley, two equal weights are attached, which

#### Gravitation

may be termeder and y. Now these weights counter-balance one another, and no motion whatever ensues; but if another small weight z be attaghed to x or y, so as to give it a preponderance, the loaded weight will immediately begin to descend freely, and its velocity will be diminished in the proportion of the additional weight z, to the sum of the original weights x and y, plus z; for the force which is impressed by the addi-tional weight z is expended not only in giving velocity to itself but elect the two wights a walk which tional weight z is expended not only in giving velocity to itself, but also to the two weights x and y, which are attached to the ends of the string. This machine thus shows that the properties of uniformly accelerated motion hold true in the descent of falling bodies; and if the additional load be such as will be able to carry the weight to which it is added through one foot in the first seconds of time, it carries it through four feet in two seconds, and through nino feet in three seconds; and so on. In order to measure the velocity of descent of heavy bodies falling rapidly, Attwood's machine could not be used with any certainty: the machine could not be used with any certainty; the only mode by which an accurate result can be obtained is by measuring the length of a pendulum, which gives a certain number of oscillations in a fixed time, as there can be no doubt that the number of oscillations there can be no doubt that the number of oscillations which it makes must necessarily depend firstly on its length, and secondly on the intensity of gravity. If the amplitude of the oscillations of the pendulum (see PENDULUM) be very small, in other words, if it does not deviate from a vertical position more than 2°, or 3° at the utmost, the relations between the gravity of the earth and the length of the pendulum will be very simple indeed; as shown by the following theory,—that the square of the number of oscillations performed in a given time is directly proportional to the intensity of gravity, and inversely proportional to the length of the gravity, and inversely proportional to the length of the pendulum. Thus if b is the length of the seconds pendulum,  $\pi$  the ratio of the circumference to the diameter, and g is the accelerating force of gravity (that is, twice the space through which a body falls by the action of gravity in the first second of time), then we have the equation that g equals  $b\pi^2$ . Therefore, as the length of the pendulum vibrating seconds of mean solar time in London in vacuo has been determined to be 39-1393 British standard inches; and as  $\pi$ , or the relation of the diameter to the circumference of a relation of the diameter to the circumference of a circle, is well known to be 314159; then we deduce the relative value of g to be 386.3 inches, or 32½ feet. The length, therefore, through which a hody would fall at London in a second of time would be  $16\frac{1}{16}$ , feet, for half the above quantity. It must be borne in mind, however, that this value of g does not express the whole of the earth's attraction, as a small part of the same (about 1-464th) is counteracted by the centrification for the corresponding to the latitude; g, therefore, was 1 force corresponding to the latitude; g, therefore, gal force corresponding to the latitude; g, therefore, is the force of gravity, diminished by the centrifugal force, or what is properly termed gravitation. It appears from many confirmed experiments, that the variation of gravitating force between the equator and the poles is as 194 is to 195; that is, a body which weighs 194 pounds at the equator, will weigh 195 pounds if transported to the poles. As the variation of the centrifugal force between the same latitudes is expressed by Newton in the fraction  $\frac{1}{16}$ , it follows that the difference between the gravitating force and the centrifugal force and the constitution of the contribution of the contributio rifugal force at the equator and at the poles might be expressed by the fraction  $\frac{1}{\sqrt{2}}$ , which difference arises from the oblate figure of the earth. It hence results, that the variation of the intensity of gravity, or, in other words, the figure of the earth, may be deduced from the number of oscillations that pendulums of the same construction would perform in twenty-four hours in places situated under different latitudes; or it might also be determined from a comparison of the different lengths which must be given to a pendulum in order that it may perform in every place the same number of oscillations in a given time. So far for the different measurements of terrestrial gravity; the second and more important portion of the article comes under the head of Universal Gravitation. Alcomes under the head of Universal Gravitation, Al-though Kepler made some shrewd guesses at the mo-tions of the planets and the causes of tides and other similar phenomens, it is to Sir Isaac Newton that we are indebted for the principles and applications of universal gravitation, and through it, by means of pure geometry (see Geometry), we are able to possess the

C

986

correct information that we have with regard to the movements of the earth, sun, and moon, and other heavenly bodies. The first rule is one which is very heavenly bodies. nesventy bodies. The first rule is one which is very comprehensive, and which gives a good idea of the whole basis of the science; it is, that the attraction of one body upon another body does not depend upon the mass of the body which is attracted, but is the same whatever be the mass of the body so attracted, provided the basis of the body so attracted, provided the same of the body so attracted. whatever be the mass of the body so attracted, provided that the distances be the same. For instance, the planet Jupiter attracts the sun, and also attracts the earth; but although the sun's mass is 300,000 times that of the earth, yet the attraction of Jupiter on the earth is exactly equal to his attraction of the sun, because the earth and sun are equally distant from Jupiter. One of the simplest illustrations of this force is that of throwing a stone in a straight or horizoutal plane, when the stone's course will be evolved in a curve, and the stone at length will drop to the ground. The flights of shot and shells are likewise illustrative of the same rule. (See Gunnery.) Newton, before applying his theory of universal gravitation, sought for a law by which he could regulate the diminishing intensity of the same, and, after several experiments and calculations, he laid down the rule that the force of gravity diminishes exactly as the square of the distance increases, or, in other words, that the attractive force of the earth at the distance of the moon must be as much less than it is at the surface of the earth, sathe square of the radius of the earth is less than the square of the moon's distance from the earth. Newton also found, that since the from the earth. Newton also found, that since the true diameter of the moon is to the true diameter of the earth as 100 is to 365, the mass of matter in the moon is to the mass of matter in the earth in the pro-portion of 1 to 39,788; and also that the accelerative gravity on the surface of the moon is to the accelerative gravity on the surface of the earth, as I is to 3, or is just one-third of that of the earth. He also proved that bodies moving under an attractive force which diminishes according to the inverse square of the distance, must describe conic sections (which see), having a focus at the centre of force; and also that they must conform to the laws of motion which Kepler discovered to belong to the planetary orbs. Newton likewise was successful in determining that most of the inequalities of the moon and planets are consequences of the mutual gravitation of the different bodies which compose the various systems upon each other; and in addi-tion, that the same incomprehensible power not only regulates the motions of the different planets and satellites, but also causes the precession of the equinoxes, produces the tidal action, and determines the figure of the earth. Gravitation, as applied to the celestial bodies, when we consider its effects, enables us to form many conclusions as to its nature, mode of action, form many conclusions as to its nature, mode of action, and influence. We see that gravity is a force which is trausmitted from body to body instantaneously, and not successively; for were we able to measure its transmission, that is, if we consider it in the light of being transmitted auccessively, we would find that the seemlar variation of the mean lunar motion would be secular variation of the mean lunar motion would be sensibly affected. If we consider the question whether gravity is affected by the density of the bodies through which it has to pass in order to attract other bodies, we would be forced to agree with Laplace, that it is of so subtle and all-powerful a matter or force that not even the densest bodies in the universe can offer any obstacle to its free passage, or retard its effects on the body to be acted upon. In concluding the subject, it may be said that if the earth's flattening at each of its poles were greater or less than 1-300th of its diameter, then the effect of this alteration on the moon would, in changing the position of its fundamental plane, thus produce an inequality in the longitude greater or less than 8', by which the moon is sometimes before or bekind her mean place. And, consequently, the deduction can be drawn, that by observing the moon, the oblateness of the earth can be discovered. As this theory has been found to be true and just in its foundation, it is one of the most striking testimonies of the correctness of Newton's laws of universal gravitation.—Ref. Newton's Principle; Arago's Astronomy, &c. &c.

"GREAT GO," AND "LETTLE GO."—Terms current
in Oxford, expressive of two different examinations
which students for the degree of B.A. have to pass in
order to obtain the same. The "Little Go," or Responsions, as the examination is termed in the calendar,
must be passed before the fifth term of residence in
the projective, but in most of the college and the university; but in most of the colleges men are required to pass it very shortly after taking their residence in the university, in their first or second term. If the candidate be "placked" (as is the technical phraseology for having failed) three times in his "little go," he is generally obliged to leave his college, and "migrate" to a "hall." Under the new system, the first public examination, or Moderations, is held from the eighth to the twelfth term, and the second public examination, or "Great Go," can be passed between the thirteenth and eighteenth terms of residence; and, being successful in the examination, the student assumes the degree of B.A.—Further information on these names, examinations, and subjects required for degrees, will be found under the articles DROBER and UNIVERSITIES.

GREAT SEAL, grait scal (Ang.-Sax.), is the exarequired to pass it very shortly after taking their resi-

GREAT SEAL, grait seal (Ang.-Sax.), is the em-GREAT SEAL, grant seal (ABE, SMAX), is the emblem of sovereignty, introduced by Edward the Confessor, and appended to all writs to summon parliament, treaties with foreign states, all public acts of state which concern the United Kingdom, and all patents and other matters relating to England. By art. 24 of the Union between England and Scotland (5 Anne, c. 8), it was provided that there should be one great seal for the united kingdom of Great Britsin, great seal for the united kingdom of Great Britain, which should be used for sealing writs to summon the parliaments and for sealing all treaties with foreign states, and all public acts of state which concern the united kingdom, and in all other matters relating to England, as the great seal of England was then used; and that a seal in Scotland should be kept and made and that a seal in Scotland should be kept and made use of in all things relating to private rights or grants which had usually passed the great seal of Scotland, and which only concern offices, grants, commissions, and private rights within Scotland. On the union of Great Britain and Ireland, no express provision was made by any article of that union as to the establishment of the seal made by any article of that union as to the establishing of one great seal for the united kingdom. But various acts (as the summoning of parliament, &c.) are required to be done under the great seal of the united kingdom, and others under the great seal of freland; and by sect. 3 of the Acts of Union, 39 & 40 Geo. III. c. 67 (British), and 40 Geo. III. c. 38 (Irish), it is enacted that the great seal may, if his majesty shall so think fit, after the union, be used in like manner as before the union (areant, where it is otherwise. shall so think fit, after the union, be used in like manner as before the union (except where it is otherwise provided by the articles of union), within that part of the United Kingdom called Ireland. Forging the great seal is treason, punishable by transportation (now penal servitude) for life, GREAVES, greecs (Sp. and Port. grevas), pieces of armour used at a very early period to defend the leg between the knee and the ankle. They formed a part of the armour of Eastern nations in the time of Sanl, as a leason from the stowy of Golisth of Sath the

of the armour of Eastern nations in the time of Saul, as we learn from the story of Goliath of Gath, the champion of the Philistines, who "had greaves of brass upon his legs." The Greeks and Romans also were metal greaves. The Saxons protected the leg by bands of cloth, the Danes by pieces of thick leather. At the time of the Conquest, armour for the legs consisted or hose, on which scales or rings of metal were fastened. When platetamour cames into use, the greaves consisted of plates of polished seed, covering the fore part of the legs. The metal shim-

#### Grebe

piece still forms a part of the picturesque dress of

the Albanians.

GERBE, grebe (Afg.-Sax.), a bird which belongs to the order Natatores, and its sub-section Columbide.

Varrell remarks, with regard to the class: "Of the true divers among our British birds, the grebes and dabchick abelong; to that division which more particularly frequent fresh water; and the great created grebe, the largest of the genus, is resident all the year in several parts of this country which afford reeds and other luxuriant aquatic vegetation, in which they find the required sequitive. They bread and remain all the required security. They breed and remain all the year, or by far the greater part of it, on some of the lakes of Wales, on the meres of Shropshire and Cheshire, on the broads of Norfolk, and in the fens of Lincolnshire. They are seldom seen to fly or walk, being mostly in the water. The form of the whole They are seldom seen to fly or walk, being mostly in the water. The form of the whole bird being that of an elongated cone, is admirably adapted for diving, and their habits can only be observed by those who live in the vicinity of their favourite pools." Besides the great crested grebe, there are the red-necked grebe, the Sclavonia, the tippet, the kittle, the korned, the cared, the dusky, and the blook-ckin grebe. The generic characters of all are, however, very similar, and are as follows:—Bill of moderate length, straight, hard, slightly compressed and over, very similar, and are as folfows:—Bill of moderate length, straight, hard, slightly compressed and pointed, forming an elongated coue; nostrile lateral, concave, oblong, open in front and perforate, closed behind by a membrane; legs and feet long, attached behind the centre of gravity; tarsi very much compressed; three toes in front, one behind; anterior toes very much flattened, united at the base, surrounded by an extended membrane; no true tail; wings short. The length of the grebe is generally between twenty-one and twenty-two inches, and from the carnal ionit. one and twenty-two inches, and from the carpal joint to the end of the longest feathers is eight inches.—
Ref. Yarrell's History of British Birds. (See also DABCHICE.)

GREEK ARCHITECTURE.-The early architecture of GREEK ARCHITECTURE.—The early architecture of Greece is exemplified in the massive remains of walls at Mycenæ, Argos, and others of the old Grecian cities, which are composed of huge, irregular, underessed blocks of stone roughly piled together. (See Cyclopean Architecture.) It is utterly devoid of CYCLOPEAN ARCHITECTURE.) It is utterly devoid of ornament, but in one or two instances examples remain of attempts to adorn the stones forming the piers and listed of a gateway with rude representations of animals, as in the principal entrance to the Acropolis of Mycene mentioned above. Grecian architecture, properly so called, was the production of a far later age, and may be traced to that of Egypt-and Western Acropolishing as it does the strength and additional actions. age, and may be traced to that of Egypt-and Western Asia, combining, as it does, the strength and solidity of the former with the more elegant features and decorative principles of the latter. The Doric, the first of the three Greek orders, assimilates more closely to the architecture of Egypt than either of the others, in its substantial and massive proportions: it is simple in character, but always conveys to the mind of the spectator a striking impression of its dignity and beauty. The Ionic order, and its ornamentation, is derived from the architecture of Western Asia, and is characterized by a greater degree of lightness in its proportions than the Doric order possesses, and the introduction of decorations in minor details. The Corinthian, the last, and by far the most elegant of the Greek orders, surpasses the Doric and Ionic orders in freek orders, surpasses the Doric and Ionic orders in its elaborate adornment and symmetry of proportion; but, even in this, a similarity to the architecture of Egypt can be traced in the bell-shaped capitals of its columns and the clusters of leaves that curl outwards from its surface. But, although each order exhibits a decided step in advance of that which precedes it, as far as elegance and ornament are concerned, the three orders were uniformly characterized by beauty and harmony of proportion; and it may be said that the buildings of ancient Greece, especially the temples, were superior to those of any climate and any age as regards simplicity of form, the purposes for which they were intended, and the habits and requirements of the people for whose use they were erected. The chief characteristics and the scale of proportions preserved in the three Grecian orders, will be found elsewhere (see Aconfricture); and the principal parts that compose what is termed an order in classic architecture have been treated under their respective headfar as elegance and ornament are concerned, the three

## Greek Architecture

ings (see Abchiteave, Babe, Capital, Column, Connice, Emtablature, Fairea), but it may be desirable to state here the particular features and marks by which each order may be readily distinguished, and to point out some recent discoveries that have been made with regard to the method adopted by have been made with regard to the method adopted by the Greeks to give the appearance of perfect beauty to their works, and to avoid anything that might offend the eye of any of this highly civilized and educated people. It should also be stated, that each order con-sists of two distinct parts,—the column and the gntab-lature,—which are again subdivided, the former into the base, shaft, and capital; and the latter into the architrave, frieze, and cornice; and that it is architrave, frieze, and cornice; and that it is by certain differences in these divisions and subdivisions that the orders themselves are distinguished. The Dorio order may be readily discerned by having no base to the column, the lower end of the shaft resting base to the column, the lower end of the shate resting immediately on the pavement; the shaft itself is also adorned with broad shallow flutings separated by a sharp ridge, the capital being composed of a broad echinus moulding surmounted by an abacus, while the frieze is adorned at intervals with projecting pieces called triglyphs, which are about half the width of the lower diameter of the column, having the appearance of being accounted to the column. of being separated into three equal parts by two verti-cal grooves cut deeply into the material of which it is formed, the horizontal section of which is in the shape of the letter V, the outer edges of the piece being chamfered off at the same angle. This order was in some instances richly adorned with sculpture in low relief along the frieze, and in high relief on the metopes or spaces between the triglyphs, the tympanum of the pediment rising in an obtuse angle above the entablature being also filled with sculpture in high relief, and frequently with perfect statues. The Ionic and Corin-thian capitals are to be distinguished from each other, the former by its volutes, and the latter by its exquisitely carved foliage and its height, which is considerably greater than that of the capitals of the Doric and Ionic orders. There is little perceptible difference in the shafts of the columns of the Ionic and Corinthian orders, or in their entablatures. The temples of the Greeks were generally placed on a level platform, consisting of three steps rising one above another, and of greater or less depth in proportion to the height and diameter of the columns that were placed upon them. These steps were too deep to afford the means of access to the temple, and it is supposed that intermediate steps were placed at intervals along the larger ones, to allow the worshippers to pass easily from one to another, and thus to gain the level of the portice. The Greek windows and doorways, like those of the Egyptians, were narrower at the top than at the bottom, the sides inclining inwards. They were generally surrounded by a moulding, which was broken at the top of the window by a right angle, and turned outwards on either side, for a short space, and turned outwards on ether side, for a snort space, in a horizontal direction, before resuming its perpendicular course, so that an architerave or lintel was formed above the window of the same width as the sill below. The doorway was always in the centre of the pro-naos, or portice of the temple, and was carried up to a considerable height for the purpose of admitting light into the interior. The arch is never employed in Grecian architecture, which is chiefly characterized by the use of the beam supported on columns, by which an appearance of great strength and solidity is obtained. It is also marked by its strict adherence to outlines formed by horizontal lines, and lines that are vertical, or nearly so, being frequently slightly inclined inwards. It is a known principle in perspective, that straight lines proceeding to a great distance in the same direction present a slightly curved appearance to the eye of an observer. To correct this appearance, the Greek architects carefully constructed their vertical and horizontal lines in the form of a very slight and scarcely perceptible ourve, giving their columns an entasis, as it is termed, or a slight outward swelling near the middle; which principle of construction was effected by means of certain fixed rules. The columns also, instead of being vertical, had a slight inclination invarials and their reasonable and the platforms or in a horizontal direction, before resuming its perpenserved in the three Grecian orders, will be found else-laso, instead of being vertical, had a slight inclination where (see Archifecture); and the principal parts which the temples stood, were constructed with a very tecture have been treated under their respective head-slight rise in the centre. Mr. Pennethorne discovered

the existence of these curves in 1837, and the truth of his statements well subsequently corroborated by Mr. Penrose, who examined many of the ruined temples of Greece, and made careful measurements of their proportions, which led to a discovery of the principles on which they were constructed. Of the three orders of Grecian architecture, the Parthenon at Athens, and the Temple of Minerva at Ægina, may be cited as the best examples of the Doric order; the Erechtheum and Pandrosium at Athens, of the Ionic order; and the choragic Monument of Lysicrates, in the same city, as the most beautiful, and almost the only oxisting pure Greek specimen of the Corinthian order. Examples of the Doric and Ionic orders, or rather adaptations of them, are common enough in the metropolis and its vicinity, the Grand Terminus of the London and North-western Railway, in Euston Square, being a specimen of the first, and the portices of the British Museum and the General Post-office, St. Martin's le Grand, and St. Pancras's Church, being examples of the second. There are but imperfect data for determining the style of architecture adopted among the Greeks for dwellings of a private character—Ref. English Cylopadia, Arts and Sciences; Fergusson's Handbook of Architecture; Penrose's

of the British Museum and the General Post-office, St. Martin's le Grand, and St. Pancras's Church, being examples of the second. GREEK, or EASTERN CHURCH, originated in the disensions that took place between the patriarchs of Constantinople and the popes of Rome. In consequence of the political position of the city as the seat of the imperial government, the church of Constantinople sought to render itself independent of the see of Rome. Disputes on various points of doctrina occurred from time to time between the two churches, curred from time to time between the two churches, curred from time to time between the two courcies, but the great breach did not take place till 802, under the patriarch Photius. He reproached the Western church with having introduced various innovations; as the celibacy of the priests, the introduction of images into churches, and the double procession of the Holy Ghost, with the addition of "filioque" (and from the Son) to the Nicene Creed. On the fall of Photius, Son) to the Nicene Creed. On the fall of Photius, however, the breach was in a manner healed, though very imperfectly, and in the 11th century dissensions broke out afresh. The final separation took place in 1054, when Leo IX. excommunicated the patriarch Michael Cerularius, who had inveighed against the corruptious of the clergy, and attacked the errors of the Western church. Several attempts were made on either side to effect a reconciliation, but in vain. The popes were anxious to effect a union in order to extend their dominions; and the emperors of Constantinople, when pressed by the Turks, attempted to obtain the assistance of the West by a promised restoration of the Eastern church to that of Rome. At a later period attempts were made by mised restoration of the Eastern church to that of Rome. At a later period attempts were made by some of the Protestant churches to come to an amicable arrangement with the Eastern church, but with like unsatisfactory results. The Greek church denies the authority of the pope, and maintains that the Church of Rome is not the only true Catholic church. It acknowledges no vicar of Christ upon earth like the pope; disclaims infallibility, works of supercrogation, and indulgences. It rejects purgatory, but admits of prayers for the dead; and forbids all kinds of carved jurgers. but cermits paintings, and pays a kind of images, but permits paintings, and pays a kind of secondary homage to the Virgin and saints. It denies auricular confession to be a divine command, but practises confession attended with absolution, and sometimes penance. It admits the seven sacraments, but baptism is performed by immersion of the body three baptism is performed by immersion of the body three times in water; and the communion of both kinds is practised with leavened bread, and the wine is mixed with water. The anointing of the body with the chrism is allowed to all sick persons as a means of restoring them to health, and purifying them from their sins. The secular clergy are permitted to marry but once, and only a virgin, and laymen are allowed to marry only three times. Like the Roman Catholic church, it accepts tradition as well as the Bible, but differs from it, as well as from all Protestant churches, in maintaining that the Holy Ghost proceeds only from the Father, and not also from the Son. The ritual of the Grock church consists almost entirely in outward ceremonies, preaching or religious instruction being rarely

strictly observed than those of the Roman Catholics. The clergy are divided into two classes,—the higher and the lower; the former comprising patrigods, metropolitans, archbishops, and bishops, all of whom are chosen from among the monks, and must live in cellibacy; the latter the monks, or black clergy (from their dress), and the secular, or white clergy. The lower escular clergy are the archpriests, priests, deacons, hypodeacons, and lectors. The monks, as well as the nuns, who are less numerous, generally follow the rule of St. Basil, with the exception of those of Mounts Sinai and Lebanon, who follow the rule of St. Anthony. One of the most celebrated convents is that of Mount Athos. The total number of persons belonging to the Greek faith is estimated at about 66,000,000; of whom about 49,000,000 are in Russia, 12,000,000 in Turkey, 3,500,000 in Austria, 800,000 in Greece, 180,000 in the Ionian islands, 125,000 in Montenegro, and about 3,000 in Prussia. As regards its government, the Greek church is made up of ten independent groups, numbering in all 279 bishoppies. 1. The Church of Constantinople, governed by a patriarch, having under him 136 bishops; 2. the Church of Alexandria, under the patriarch of Alexandria, who resides at Cairo, and has five bishops; 3. the Church of Antioch, with its patriarch and 14 bishops; 4. the Church of Jerusalem, with its patriarch and 14 bishops; 5. the Russian Church, with 60 bishops, governed by a synod; 6. the Church of the island of Cyprus, with four bishops; 7. the Austrian Greek Church, with 11 bishops; 8. the Church of the island of Cyprus, with four bishops; 9. that of Montenegro, with one bishop; and 10. the Hellenic Church in Greece, with 24 archbishops and bishops. Besides these ten divisions of the Greek church, which recognize each other as orthodox, there are a number of sects, particularly in Russia, which fully acknowledge the doctrinal basic of the Greek church, but for various reasons keep aloof from it. The Greek church predominates in all Russia, Europe strictly observed than those of the Roman Catholics The clergy are divided into two classes,—the higher and reasons keep aloof from it. The Greek church pre-dominates in all Russia, European Turkey, Greece, the lonian islands, and Montenegro. In Turkey, the the lonian islands, and Montenegro. In Turkey, the patriarch of Constantinople has not only spiritual, but also a kind of temporal jurisdiction, as he is regarded by the Turkish law as the head of the Greek Christians. who have to pay him a yearly tribute. The Russian Greek church asserted its independence on the fall of Greek church asserted its independence on the fall of Constantinople? in the middle of the 15th century, when a patriarchate was established at Moscow. The natriarchate was abolished by Peter the Great, who organized a supreme court for the regulation of spiritual matters, to six at the new capital of St. Petersburg. Since that time the Church of Russia has been virtually contained that the Care The Visited Great Church since that time the Church of Russia has been virtually controlled by the Car. The United Greek Church is a section of this body, which, by the continued efforts of the Roman church, were induced to acknowledge the supremacy of the pope, while they, on the other hand, were permitted to abide by all the peculiar usages of the Greek church which did not effect furthermental destricts. peculiar usages of the Greek church which did not affect fundamental doctrines;—as the use of the Greek language in divine servise, the reception of the Lord's supper in both kinds, &c. &c. In Russia, almost all the members of the United Greek church were induced, under the reigns of Catharine II. and Nicholas, to dissolve their connection with the Church of Rome; and active their connection with the Church of Rome; and at present this section of them is most numerous in Austria. For an account of the festivals, ceremonies, liturgies, &c. of the Greek church, see the Rev, John Mason Neale's History of the Eastern Church.
GREEK FIRE. (See FIRE, GREEK.)
GREEK MUSIC.—Until quite a recent period it was believed that the art of music had attained to a high

suricular confession at the dead with absolution, and some times penance. It admits the seven sacraments, but baptism is performed by immersion of the body three times in water; and the communion of both kinds is practised with leavened bread, and the wine is mixed with water. The anointing of the body with the chrism is allowed to all sick persons as a means of restoring them to health, and purifying them from their sins. The seculer clergy are permitted to marry but once, and only a virgin; and laymen are allowed to marry only three times. Like the Roman Catholic church, it accepts tradition as well as the Bible, but differs from it, as well as from all Protestant churches, in maintaining that the Holy Ghost proceeds only from the Father, and not also from the Son. The ritual of the Grock church consists almost entirely in outward cere in maintaining that the Holy Ghost proceeds only from the Father, and not also from the Son. The ritual of the Grock church consists almost entirely in outward cere of the differs from the son are the long of the best of the arts and sciences." All that are known to be in existence of the old Greek music are a few hymns and an ode by Pindar. Even these fragments are held to be spurious by some archaeologists.

#### Greek Language and Literature

GREEK LANGUAGE AND INTERATURE.—The earliest inhabitants of Greece were the Pelasgi, who, according to Herodotus, spoke a barbarous or foreign tongue. They were allied to the Iraman tribes of the north of India; consequently, that element in the Greek lan-India; consequently, that element in the Greek language which exhibits an affinity for the Sanscrit, is the Pelasgic; and hence the strong resemblance in words and inflections, which is found to exist between the two languages. The Hellenes, or Greeks proper, subsequently migrated into the country, and the language of the aboriginal inhabitants came to be looked upon as barbarous. The Hellenes were an Ionian race, and their language is said to have had an affinity to the Persian. It is but right to state, however, that this account of the origin of the Greek language is not universally received, for the subject is so involved in doubt, that no certainty can be arrived at regarding it. The Greek is a branch of the so-called Indo-Germanic, The Greek is a branch of the so-cashed indo-Germanic, or Aryan family of languages. It consists of three principal dialects,—the Æolic, Doric, and Ionic; to which at a later period was added the mixed Atticulated; and besides these there were several minor dialects. The Doric was a rough, hard, broad dialect, with long a predominant over all the other vowels. It was spoken originally in the mountains of Thessaly, whence it travelled southward, and became the lan-guage of the greater part of the Peloponnesus. It was purest in Messenia, and softest in Syracuse and Agrigentum. Its centre was Sparta. It is found in the gentum. Its centre was Sparta. It is found in the writings of Pindar, Theocritas, Bion, and Moschus. The Æolic was a more ancient dialect than the preoeding, but was refined at an earlier period, and was less harsh than the Doric, although also broad and open. It was spoken north of the Isthmus of Corinth (with the exception of Megaris, Attica, and Doris), in the Æolic colonies of Asia Minor, and on some islands of the Ægean sea. It contains some of the Pelasgic forms, and is to be found in the fragments of Sappho, Myrtis, and Alexes. The Ionic is the softest and most musical of all the dialects. It abounds in vowels and diphthongs, and is partial to labials and linguals. It was the earliest cultivated of the dialects, and is that of Homer, and other of the early authors, as Hesiod, Herodotus, &c. It was spoken principally by the people of Attica and the Ionian colonies of Asia Minor. The Attic sprang from the Ionic, from which at first it differed but little. It was developed principally after the Persian wars, and was brought to perfection by the poets, philosophers, and historians of Greece, who flourished after that time. It held a middle place between the hardness of the Adolic and Doric and softness of the Ionic. It was harmonious and powerful in its expressions, concise and regular in its syntax.

Rachelus. Sophocles, Euripides, Thucydides, Aristo-Richylus, Sophoeles, Euripides, Thucydides, Aristo-phanes, Plato, Demostheues, and Isocrates, rendered it immortal. Grammarians afterwards distinguished between the genuine Attic, as it exists in these masters, and the Attic of common life, calling the latter the common Greek, or Hellenic dialect; and even the later common Greek, or Hellenic dialect; and even the later attic writers, posterior to the golden age of the literature, were called Hellenes, or common Greeks. In this latter class are Aristotle, Theophrastus, Apollodorus, Polybius, Plutarch, and others, many of whom, however, wrote genuine Attic.—At what time this language first began to be expressed in writing is a question of much uncertainty. According to tradition, Cadmus the Phænician introduced the alphabet Cadmus the Phonician introduced the alphabet into Greece about 1500 years B.O. To him, sixteen of the letters of the present alphabet are attributed; four, according to Pliny, were introduced by Palamedes at the time of the Trojan war, and four by Simonides of Ceos during the Persian war. The ancient letters were all uncial, or what we call capital; the present cursive or round letters occur first in inscriptions of the age of Augustus, and recombined. inscriptions of the age of Augustus, and resemble the Coptic forms. The Greeks wrote originally from right to left; afterwards alternately, the one line from right to left, and the next from left to right (called boustrophedon, as being the mode in which oxen ploughed in a field); and finally from left to right, as we do now. The Greek language is a branch of the great Indo-Germanic family of tougues. It is rich in roots, flexible in the formation of words, picturesque

# Greek Language and Literature

Anacreon, majestic in Æschylus and Pindar, noble in Sophocles, pathetic in Euripides elegant in Xenophon, subtle in the Sophists, distinct in the Stoies, clear in Aristotle, and fluent in the orators. Its syntax is free, full of inversions, subtle and perfect, yet without obscurity. Its antiquity, its intrinsic excellence, its literature, and its influence on the progress of the fairest portion of mankind, challenge our deepest admiration. "In order," says Mure, "to the attainment of the highest excellence, it is essential, first, that a language should be the original invention of the people who speak it; secondly, that this people should be gifted not only with a fine sense of emphony, but with variety and extent of intellectual powers. These lence, its literature, and its influence on the progress favourable circumstances were combined in the case of the Greek in a greater degree than in that of any other known language. While it is in all essential respects a radically original tongue, its mechanism, both in sound and structure, reflects all the harmony, versatility, and precision, which mark the genius of the race by whom it is spoken."—(Language and Literature of Ancient Greece.) The language of modern Greece is what is termed Romaic, or Neo-Hellenic. It differs from the ancient Greek chieffy in the formation of the the Greek in a greater degree than in that of any other from the ancient Greek chiefly in the fermation of the tenses, and in the termination of the nouns; but the difference between the two is not greater than between the Doric and the Attic dialects of ancient Greece. The tendency of late years has been to assimilate it more and more to the ancient tongue; and a good ancient Greek scholar will have little difficulty in ancient Greek scholar will have little difficulty in making out a Greek newspaper of the present day, The origin of Greek literature is lost in the darkness of antiquity. The earliest existing monuments of it carry us back to nearly 1000 years D.o., and even then we find the art of poetical composition existing then we find the art of poetical composition existing in the highest perfection. The admirable structure and the wonderful language of the Homeric poems imply a long period of antecedent culture. Although both the Iliad and Odyssey display traces of the infancy of the nation, and manifest a spirit of simplicity peculiar to the childhood of the human race, "yet the class of poetry under which they fall appears in them at its full maturity; all the laws which reflection and experience can suggest for the epic form are observed with the most refined taste; all the means are em-ployed by which the general effect can be heightened; nowhere does the poetry bear the character of a first essay or an unsuccessful attempt at some higher poetical flight; indeed, as no subsequent poem, either of ancient or modern times, has so completely caught of ancient or modern times, has so completely enigne the genuine cpic tone, there seems good reason to doubt whether any future poet will again be able to strike the same chord."—(Miller.) Of the poets prenames of many of them, as Olen, Linus, Orpheus, Museus, and many others, are preserved to us; but their works are all lost. The poems which have come down to us under their names are manifest forgeries. The Iliad is founded on the legends of the war of Troy; The Hiad is founded on the legends of the war of Troy; the Odyssey, on the return of Odysseus (Ulysses), Various other poems, as the "Batrachomyomachia," or Battle of the Frogs and Mice, are attributed to Homer; but they evidently belong to a later period. The Homeric poems were made use of as models, and as a basis with which to connect their works, by a series of later poets, who are commonly known as the "cyclic," but of whose works only the titles, brief abstracts, and fragments, have been preserved. Heaiod, the next great epic poet after Homer, was a Boxotian, and is believed to have flourished about the middle of the 9th century before Christ. His principal poems are the "Works and Christ. His principal poems are the "Works and Days," the leading subject of which is the various occupations and duties of life in its several relations; and the "Theogonia," containing a history of the loccupations and duties of life in its several relations; and the "Theogonia," containing a history of the origin of the world and the genealogies of the gods. Lyric poetry arose on the decline of the epic, and was much cultivated from about B.O. 776 to the commencement of the Persian wars. The spirit of the times and the various contests in which the different states were engaged, greatly favoured this kind of poetry. Next to the gods, who were celebrated at their festivals with lyrms, their country, with in its modes of expressing thought, highly plastic and its heroes, was the leading subject of their song; and suphonious; simple and sublime in Homer, playful in in everything there was a more powerful impulse to-

970

#### Greek Language and Literature

wards meditation, investigation, and labour, for the attainment of a desired end than before. Among those who were distinguished in the field of lyric poetry, or in the improvement of music, history furnishes us with the names of Archilochus of Paros, inventor of the iambus; Tyrtsous of Miletus, author of war songs; Callimachus of Ephesus, inventor of the elegisc me sure; Aleman the Lydian; Arion of Methymna, who sure; Aleman the Lydian; Arion of Methymna, who perfected the dithyrambus; Terpander of Antissa, investor of the burbitos (a kind of lyre); the tender Sappho of Mitylene; her countryman Aleœus; Eriuna, the contemporary of both; Minnermus of Colopbon, the flute-player; Stesichones of Himera; Ibyeus of Rhegium; Anacreon and Simonides of Coos; Hipponax of Ephesus; Timocreon of Rhodes; Lasus of Hermione; Corinna of Tanagra, the friend and instructress of Pindar. As gnomic writers, Theognis, Phocylides, and Pythagoras, deserve to be named; and as a fabulist, Æsop. In the order of time, several of these belong to a later period, but they are troperly placed here, on account an the erder of time, several of these belong to a later period, but they are properly placed here, on account of the connection. The greatest of all the masters of lyric sung, however, was Pindar, born at Cynosec-phalte, in Bootia, in Euc. 522. Of his numerous com-positions, we have only the four series of Epimeian odes, i. e., odes written in commemoration of victories gained at the four national festivals,—the Olympic, Pythian, Nemean, and Isthmian. The earliest writers Pythian, Nemean, and Isthmian. The earliest writers of prose were those who first engaged in philosophical speculations. Of their writings, however, only a few fragments have been preserved. Thales was the founder of the Ionic philosophy, to which belonged Pherecydes, Anaximmeder, Anaximenes, Anaxagoras, &c. Pythagoras established the Italian school, and was followed by Alomeon, Timans, Epicharmus, Theages, Archytas, and others. In history the Ionians took the lead. Cadmus of Melitus, about 540 B.O., is the earliest; Acesilaus of Argos soon followed; then Pherecydes of Leros, Charon of Lampsacus, Hellamicus of Mitylene, Dionysius of Melitus, all of whom proceded Herodotus, but are rather chroniclers than historians, in the strict but are rather chroniclers than historians, in the strice but are rather chroniclers than historians, in the strict sense of the term. The first great historian was Hero-dotus of Halicarnasaus (18½ n.c.), whose delightful work is still preserved, and well entitles him to the name of the "Father of History." The drama took its rise from the festivities with which the country people solemnized the gathering in of the vintage, and which were accompanied with songs and dances. By degrees, variety and some measure of art were given to these proceedings. The first direct step to the introduction of the drama was made by Thesnis, who added action of the drams was made by Thespis, who added action to the chorus (B.C. 536), and who exhibited on movable stages, at the cross-ways or in the villages. He was followed by Phrynichus, who flourished B.C. 511, and who was the first to bring female characters upon the who was the first to bring female characters upon the stage. Æschylus, the great perfecter of the tragic art, was born at Eleusis 525 B.C. He first substituted actors who repeated their parts by rote, in place of an intermediate speaker, who related his story extemporaneously. Sophocles and Enripides, the other great masters of Greek tragedy, flourished soon after Æschylus. Comedy was first brought into regular form by Epicharmus, who lived about 500 B.C. Cratinus, Crates, Phrynichus, and Emplis, are well-known names in this Phrynichus, and Eupolis, are well-known names in this field: but the greatest is Aristophanes, who flourished nea; out the greatest is Aristophanes, who flourished in the early part of the 5th century B.C., and of whose comedies eleven have come down to us, though he is said to have written fifty-four. In what is termed the "old comedy," public and private characters were introduced by name; but subsequently it was forbidden by law to introduce any living paragraphs. by law to introduce any living person by name, and what is known as the "middle comedy" arose in consequence. The "new comedy" was a still farther modification, which comedy first assumed in the age of Alexander. Of the middle comedy period, only a few fragments of committee here became any committee of committee here. sequence. The "new comedy" was a still farther modification, which comedy first assumed in the age of Alexander. Of the middle comedy period, only a few fragments of comedies have been preserved. The carliest writer of new comedy was Philippides, who flourished 323 n.c.; and the two most celebrated of his successors were Philemon and Menauder. The fertility and excellence of the Greek dramatic literature were most remarkable. The prose compositions that belong to this age were equally distinguished by their duels to this age were equally distinguished by their duels to most remarkable. The prose compositions that belong to this age were equally distinguished by their duels (nor 471 n.c.), whose work on the Pelcoponnesian war is not only the first specimen of what has been called philosophical history but remains unsurpassed

## Greek Language and Literature

down to the present time. The historical works of Xenophon (born 447 n.C.), though not equal to that of Thuoydides in vigour of colouring and depth of reflection, are yet adorned with every grace of narrative and description. His other works are valuable for the light they throw on the spirit of Greek institutions and the peculiarities of Greek life. Of the works of Otesias, Philistus, Theopompus, and Ephorus, which belong to a period somewhat earlier, none have come down to us entire. In philosophy, to which the toachings of Socrates (born 448 B.C.) gave a great impulse, we have the writings of Plato (born 428 B.C.), and his pupil Aristotle (born 384 B.C.). Plato was endowed with a brilliant imagination, and loved to sear into the highest regions of imagination, and loved to soar into the highest regions of speculation; while Aristotle was a student and observer, practical results being the objects of his investigations. Plato's sense of the beautiful was exquisite, and his style was at once idiomatic and lofty; while in passages it moved in a rich and stately music which all ages have admired. Aristotle's style, on the other hand, was terse, logical, close, seldom adorned with poetical embellishments, and never with rheterical exaggerations. He never entered the world of ideas with Plato, but everything he wrote embedded the results of careful and extensive observations, or comparison of observations. His works embrace the subjects of observations. His works embrace the suppers or logic, rhetoric, physics, metaphysics, natural history, and politics. Plato founded the Academic school, whose point of reunion was the Academy on the Cephissus, north of Athens. Aristotle established the Peripatetic school in the Lyceum, near the Hissus, on the carrest raid of the sity. In the same period Peripatetic school in the Lyceum, near the lissus, on the opposite side of the city. In the same period, political eloquence, always a characteristic form of Greek eloquence, reached its highest perfection. Public discussion was the general rule in the Greek republics. In Athens, especially, it was indispensably necessary for the statesman who wished to acquire any influence to be an eloquent public speaker. Solon, Pisistratus, Miltiades, Aristides, Themistocies, and Pericles were orators as well as legislators, counsellors, and generals. Pericles was the first to cultivate the art, and to adorn his mind with the teachings of philosophy and general literary culture. The first rhetorical school at Athens was opened by Georgias of Leontini. school at Athens was opened by feorgas of Leontin.
Other sophists and teachers of rhotoric were Protagoras, Prodicus, Hippias, &c. Among the Athenian
orators whose works are extant, in whole or in part,
By Antiphon, Andocides, Lysias, Isocrates, Lyourgus,
Hyperides, Eschines, Demades, Demosthenes, and
Dinarchus. Mathematics was now cultivated, and geography served to illustrate history. Astronomy is indebted to the Ionic school, arithmetic to the Italian, indebted to the Ionic school, arithmetic to the Italian, and geometry to the Academic school, for many discoveries. As mathematicians, Theodorus of Cyrene, Meton, Euctemon, Archytas of Tarentum, and Eudozus of Cnidus, were celebrated. Geography was particularly enriched by voyages of discovery, which were occasioned by commerce; Hanno's voyage to the western coast of Africa, the Periplus of Scylax, a description of the coasts of the Mediterranean, and the discoveries of Pythias of Massilia in the north-west of Europe, deserve mention. The study of nature was GISCOVERIES OF TABLESS OF DIABESTIAN IN THE MOTAL-WEST OF Europe, deserve mention. The study of nature was likewise pursued by the obliosophers; and the healing art, hitherto practised by the Asclepiades in the temples, was raised to a distinct science by Hippo-crates. The expeditions and schievements of Alexancrates. The expectations and active tense to instant der furnished abundant materials for history and study; but, on the whole, the gain was rather in extent than in value. After the death of Alexander, although literature still continued to be cultivated in Greece, yet, till the Roman conquest, the principal seat of letters and science was Alexandria; and this

the west, are two parallel series of writers,—the Pagan, and the Jewish and Christian. Of the former, the most important are Babrius, Strabo, Epicetus, Plutarch, Dion Chrysostomus, Arrian, Pausanias, Marcus Antopinus, Aristides, Lucian, Diogenes Laërius, Achilles Tatius, Dion Cassius, Atheneus Herodianus, Philostratus, Plotinus, Longinus, Iamblichus; of the latter, Josephus Philo, the suthors of the books of the New Testament, Clement of Rome, Justinus, Polycarp, Irensus, Clemens of Alexandria, and Origen. During the long period which elapsed between the establishment of the seat of government at Constantinople, A.D. 330, and the capture of that city by the Turks, A.D. 1433, the names in Greek literature are comparatively few. They comprise the series of outhors known as the Byzantine historians; the ecclesiastical and other writers, as Eusebius, Athanasius, Gregory Nazianzen, Epiphanius, Synesius, Socrates, Basilius, Georgius Pisides, Malales, Georgius Syncellus, Nicephorus, Photius, Constantine Porphyrogenitus, Leo (Philosophus) Theodosius; the rhetoricians and grammarians; a few poets, as Moschus, Quintus of Smyrna, Coluthna, Agathas; and in the 12th century, Ptochoprodromus; the romance writers Longus Kenophou of Ephesus, Heliodorus; the historians, as Zosimus, Procopius, Anna Comnena, and her husband Bryennius, Chalcocondylas, &c. After the capture of Constantinople, intellectual pursuits languished under the tyranny of the Turk. Since the establishment of the Greek kingdom, literature has made great progress in Greece. In the department of education, the publications have been innumerable. In history, works of distinguished morit have appeared, as the history of Fyernhebes, whose works are quoted with approbation by Niebuhr; the series of histories by Professor Paparrhegopoulos, distinguished by the eloquence of their style and the animation of their narrative; and the "History of the Greek Revolution," in four volumes, by Triccupos. In cultivated poetry, we may mention the works of Rizos, of Alexander an the west, are two parallel series of writers,—the Pagan, and the Jewish and Christian. Of the former, the "History of Greek Literature" by Asopios, will sustain a fair comparison with similar works in other European countries; while the lectures and occasional discourses of the professors in the university, among whom we may mention Asopios, Pericles Argyropoulos, Philippos, and Kontogones, have great merit in point of style and learning. Many newspapers and other periodicals are now published at Athens and other veel to be making rapid advances. Much that augurs well of their future success may be gathered from their conduct during and since their recent revolution (1862)—Ref. Browne's History of the Literature of Ancient Greece, continued by J. W. Donaldson (3 vols. Svo. London, 1853; Critical History of the Language and Literature of Ancient Greece, by William Mure (5 vols. London, 1855, 57,—not completed).

General Periodophy.—The philosophy of ancient Greece is important, as being the great source of all subsequent speculation. Down to a recent period, the works of the two great masters, Plato and Aristotle, were universally received and followed. Having given special articles on these two systems (see Aristotes Largery Periodophy Periodophy and Pe sustain a fair comparison with similar works in other

origin of nature and the original matter of the world. The earliest of the schools was the Ionian, beginning with Thales, who held that water was the original ele ment whence all things proceeded. Among his folment whence all things proceeded. Among his tollowers were Auaximander and Anaximenes, the latter of whom regarded air as the primary element of all things. The Italian, or mathematical school, was founded by Pythagoras, who was distinguished by his knowledge of the mathematical sciences, and defined numbers to be the principles of all things. The Eleatic school, so called from Eles, in Italy, from finding creation incomprehensible, pronounced experience a mere appearance, and endeavoured to determine the nature of things merely from notions of the understanding. Xenophanes, Parmenides, Molissus, and Zeno belonged to this school. Opposed to the Eleatic was the Atomic school, at the head of which were Leucippus and Democritus. They asserted the external world to be real, and all things to be made up of minute atoms, invariable, indivisible, and imperceptible, owing to their extreme tenuity. From these contending schools arose the class of the Sophists, who, being skilled in the arts of dislectics and rhetoric, distinguished themselves as disputants, and, pretending to universal knowledge, they entirely undermined all lowers were Auszimander and Anaximenes, the latter of guished themselves as disputants, and, pretending to universal knowledge, they entirely undermined all earnest striving after truth, and destroyed the difference between truth and error. The chief of the sophists were Gorgias, Protagoras, Prodicus, Hippiss of Elis, Polus, Thrasymachus, and Callicles. The sophists compelled their antagonists to seek for some solid foundation on which philosophy might take its stand, and introduced the second period of its history, which begins with Socrates. The earnestness and they output here of Socrates convend itself to the shallowtory, which here is with Socrates, The earnestness and thoroughness of Socrates opposed tiself to the shallowness and dippancy of the sophists. From looking merely at external nature, he taught man to look inwards upon himself. His system was more practical than speculative, regarding the great object of philosophy to be the attainment of correct ideas respecting man's moral and religious obligations, and the perfection of his nature as a rational being. Among the followers of Socrates, who especially devoted themselves to the pursuits of philosophy, were Antisthenes the Athenian, founder of the Cyrine school; Aristippus, chief of the Cyrenaic, and Pyrrho, gave their attention exclusively to questions of morals, and their practical application; while Euclid of Megara, Phædo of Elis, Menedemus of Trebria, were occupied with theoretical or metaphysical inquiries. The more comprehensive genius of Plato inquiries. The more comprehensive genius of Plato embraced at once both these topics, and attempted to combraced at once both these topics, and attempted to build up a complete and connected system of philosophy. (See Platonic Philosophy.) His scholar Aristotle, characterized by a great knowledge of nature, as well as by great logical and reflective powers, became the founder of the Peripatetic school. (See ARISTOTELIAN PHILOSOPHY.) The Cynical school finally merged in that of the Stoics, and the Cyrenaic in that of Epicurus. From this time (about n.c. 300) dates the commencement of the third period of the history of Greek philosophy.—that of its decline. The contests between the different schools led to a spirit of doubt being introduced into philosophy. The contests between the different schools led to a spirit of doubt being introduced into philosophical speculation, scepticism began to prevail, and attempts were made to unite the different contending parties in a system of celecticism.—Ref. Lewes's and Tennemann's Histories of Philosophy.

eclecticism.—Ref. Lewes's and Tennemann's Histories of Philosophy.

GREEN HELLEBORE, green (Sax. grene, green; Lat. helleborus, hellebore). (See Verateur.)

GREENBACKS, the familiar name by which American notes are known. The manufacture of a paper for these notes, combining the qualities of wear, and being splitless and unphotographic, was a much-desired desideratum. Accordingly it was resolved to make some experiments, which were intrusted to Doctor Grayno, who, produced a paper as firm as parchment. were nuiversally received and followed. Having given special articles on these two systems (see ARISTOTRIJAN particles and the see notes, combining the qualities of wear, and being aplifiess and unphotographic, was a much-desired desideratum. Accordingly it was resolved to make the summary of the see notes, combining the qualities of wear, and being aplifiess and unphotographic, was a much-desired desideratum. Accordingly it was resolved to make Gwynn, who produced a paper as firm as parchment, there periods,—its youth, its maturity, and its decline. The first period extends from the time of Thales to that of Socrates (600 to 400 n.c.), and is characterized by a striving after a knowledge of the ultimate causes of nature and liberty, in which reflection was not yet systematized nor separated from poetry. The Greek mind elevated itself through poetry to philosophy. The sheegonies, cosmoding it is more and increased the second of the second o

Greenfinch

printing these notes is made in mills, six in number, for making as many different colours. Each one is called a 4-horse-power mill, though the whole six are driven at the same time by an engine which one could pick up with one hand. It not only turns these mills, but at the same time runs three Hoe-cylinder presses. but at the same time runs three Hoe-oylinder presses. In the engraving-room science and art are both displayed to perfection. There is, perhaps, no engraving so fine, and requiring so much time to execute, as that on the plate now being prepared for national note-printing: one the size of a bill, on which the workman has been employed almost a year, is a copy of one of the paintings in the rotunds of the Capitol. The figures are of exquisite proportions and the water. figures are of exquisite proportions, and the water-lines, though plain, extremely delicate in their tracery, lines, though plain, extremely delicate in their tracery. With the single plate, as it comes from the hande of the engraver, it would be impossible to do the printing required, and as it is equally impossible to have a number of plates engraved, it becomes necessary to repeat them in another way. This is done in the following manner:—The engraving is made on a plate of soft steel just the size of the bill or bond, and the cuttings are indentations. When flushed, the plate is hardened and taken to a "transfer-press," where a roller of soft steel, of just the circumference to take in the size of the plate, is rolled over it under heavy pressure, leaving the impression on the roller in a raised form. This roller is in turn hardened, and then any number of flat plates similar to the original then any number of flat plates similar to the original are prepared, and receive in like manner the impression from this roller, and become fac-similes of the plate engraved, and we have produced in a few minutes what it has taken months with chisel and eyeglass to make. The printing is now done on the old-fashioned make. The printing is now done on the old-lasshored engraver's press, being nothing more than a simple iron roller covered with cloth and paper, to press the printing-paper into the indentures, placed in a strong frame, and turned back and forth by hand by spokes placed in the end of the roller. Two persons work at placed in the end of the roller. Two persons work at each press—a man and a woman, the former attending the plate, the latter the paper. The plate is kept warm while working by a gas heater. The sheets when printed are each laid between other sheets of thin brown paper, to keep them from blurring, and sent in hundreds to the drying-room. The first process of bond-printing is numbering the coupons and the denomination with a yellow mordant, and as they fly from the press, they are bronzed, as they appear when issued. Yellow is used because it cannot be photographed without showing too plainly to be mistaken, as was remarked about the fibre in the paper. This discovery was made in the following manner:—When Mr. Clark was at the head of the Bureau of Construction, he had a map made for military pur-Construction, he had a map made for military purposes, which it was necessary to repeat. It was photographed, and an obscure road marked with a faint yellow line was discovered to be black in the copies. yellow line was discovered to be link: in the copies. He then photographed a specimen-sheet of inks or paints, and of all the colours except black, yellow was the only one which might not have been altered with ease by a touch of the brush. It was black as the black ink itself. Hence any attempt to photograph this colour will only lead to the discovery; and as it black ink itself. Hence any attempt to photograph this colour will only lead to the discovery; and as it is the groundwork of bonds and other securities, and covered by the printing, it seems another security against fraud. The series-numbering is the last process before trimming. The work is done by women, the machines being worked by a treadle. The figures are placed in the edges of six discs, placed side by side, and fastened to an arm worked by the treadle something after the style of a Wheeler & Wilson sewing-machine. The discs are turned by a ratchet, and will number from 1 to 990,990. For consecutive numbering a little hook is attached to the ratchet, and the machine shifts itself. Otherwise the discs are turned by the number. The trimming and cutting were formerly done by hand, and, of course, very imperfectly and laboriously. There were two things to be overcome in cutting by machinery,—the inequality of the registry and the shrinkage. It was desirable that the edges should be trimmed so that they would wear well. If cut with a straight knife, they would be beveiled one way. As they are now cut, with circular the shrinkage and the ways. The and will number from 1 to 999,990. For consecutive numbering a little hook is attached to the ratchet, and the machine shifts itself. Otherwise the discs are turned by the number. The trimming and cutting were formerly done by hand, and, of course, very imperfectly and laboriously. There were two things to be overcome in cutting by machinery,—the inequality of the registry and the shrinkage. It was desirably that the edges should be trimmed so that they would wear well. If cut with a straight knife, they would be bevelled one way. As they are now cut, with circular bevelled one way. As they are now cut, with circular large of the place, and two hundred yards beyond thagstes. Generally, and two hundred yards beyond thagstes, of the place, and two hundred yards beyond the place, and two hundred yards beyond the place, and two hundred yards beyond the place, and two hund

trims the margins, and another separates them: this latter is an ingenious contrivance. It slits them very fast, and lays them regulary in, a box, each series of numbers separately. The notes are lettered A. B. C. fast, and lays them regulary in a box, each series of numbers separately. The notes are lettered A, B, C, and D, and the numbers on each are the same; therefore it is essential they should be kept carefully apart. Each of the boxes that receives them has a movable bottom. When the cutting for the day first commences this bottom is near the top of the box; but as the cutting progresses, and the number of the bills increases, a ratchet lets the bottom drop the thickness of a bill, so the box is kept just so full at the time to make the bills slide in without doubling. It is intended that the cutting should be a criterion by which to judge of the genuineness of the bills, for every one must be the same width and length. If the end of a must be the same width and length. If the end of a bill be placed on the centre of another, there will be must be the same width and length. If the end or a bill be placed on the centre of another, there will be found no difference in the width,—an exactness which cannot be given by the hand. The currency cuttingmachine is more complicated, as it cuts both ways and files them in bundles of five dollars each, and we are not sure but it binds and seals them. Wet printing is the process now used in this establishment. The wetting is done by cloths, instead of by dipping or sprinkling as in newspaper printing. A room is prepared especially for this, with iron weights for pressing. Each man has his particular place assigned him, and all work in harmony, and with precision and celerity. Ordinary bills are wet and dried three times during the printing. To do this some eighty heavy hydraulic printing-presses are being set up, when what is called dry-printing, or printing on dry paper, will for the first time be successfully performed. There is a very perceptible difference between the present way and the one to be substituted. Specimen sheets show a clearer impression and a remarkable distinctness. a clearer impression and a remarkable distinctness, with which the faintest water-line is made to stand boldly out. This process, which is entirely new, has only been introduced after the most vehement and virulent opposition. The first tests were made with hand-pumps; machine-pumps are now being rigged, and the whole will soon be in motion. There has been added to the measure of the pumps a regulator in the shape of a weight, which is intended to take up their lost power as their force is exhausted; take up their lost power as their force is exhausted; thus keeping up nearly the same pressure all the time. The clacks and safeguards upon every one employed in the department, from the claif down to the lowest labourer, operate at every turn. Not even a clauk sheet, much less a printed paper, is passed from one hand to another without being counted and receipted for; and unless there is collusion from one to another through every process under which the receipted for; and unless there is collusion from one to another through every process under which the paper has to pass before it is money,—through the entire range, there cannot be an over-issue. The paper is issued from one room, and is re-issued from that room sixteen or eighteen times before it is put into circulation; being counted, charged, and re-receipted for each time, and re-counted, re-charged, and receipted for through each process that it passes after leaving this room. Five hundred persons are employed in note, bond, and currency making. By the present process of printing, each pressman takes above five hundred impressions per day. By the introduction of hydraulic presses the rate of production of these elaborately-prepared notes may be estimated at from three to five hundred impressions per hour.

CHERN CLOTH, BOARD OF, is a court of justice connected with the royal household, sitting under the lord high steward, and attended by various officers of the household. It has the charge and supervision of the royal household in all matters of justice and

#### Greenhouse

colour. The greenfinch is very common in England, and it is easily tamed. It imitates the songs of other birds, but is not much prized as a native songster. (See GROSBBEK.)

GREENPINCE.

GREENHOUSE, green'-house, in Gardening, a house with a roof and sides of glass, which is used for the cultivation and forcing (see FORCING) of plants which are too tender to endure the open air all the year, or which have been imported from foreign countries. The first of these stagectures appears to have been erected in the 17th century, acording to Loudon, who states that the earliest was planned and carried out by one Soloman de Caus, of Heidelberg, about the year 1619; in order to shelter some orange-trees which had been transported to the gardens trees which had been transported to the gardens of trees which had been transported to the gardens of the town. It is stated in Brande's Dictionary that the greenhouse, "being a structure of luxury, ought to be situated close to the house to which it belongs; and that its length and breadth may vary at pleasure, but that its height should never be less than that of the loftiest apartments from which it opens." The best aspect for greenhouses is the south or south-east, as in those facing the north or east delicate plants will not thrive so well in winter. In most of these buildings the plants and shrubs are placed in pots or boxes, which are placed on different stages or forms, so that the heat may be regulated to suit their different requirements. Sir Joseph Parton, the architect of the Great Exhibition of 1851, has plauned and erected some of the best examples of greenhouses and similar structures. (See also separate articles on Conservatory, Hothouse, and Orangery.)

GREENLAND WHALE. (See WHALE.)
GREEN-ROOM is the name given to the actors' retiring-room in a theatre, and was originally conferred probably on account of its being painted or otherwise ornamented with green.

ornamented with green.

GREEN-SAND, in Geol., the term applied to the lower portion of the cretaceous system (which see) as developed in the south of England, from the greenish colour of some of the beds of sand.

GREEN SCHERLES B.—An arsenite of copper.

GREENSTONN, in Geol., a general name for the hard granular-crystalline varieties of trap (which sec), consisting mainly of felspar and hornblende, felspar and augite, or felspar and hypersthene. The term has reference to the greenish or blackish-green colours which these igneous rocks commonly though not invawhich these igneous rocks commonly, though not invariably, exhibit.

GREEN VITRIOL. (See IRON, SULPHATE OF.)
GREEN ULTRAMARINE. (See ULTRAMARINE.)
GREGARIOUS ANIMALS, gre-gai-re-us (Lat. gregarius,
from grez, a hord), is a term applied, in Nat. Hist., to
those saifhals which have the habit of assembling or living in flocks or herds.

GREGORIAN CALENDAR. (See CALENDAR.)

GREADER, gre-naid (Sp. granado), a missile invented and brought into use about 1694, consisting of a small shell about two or three inches in diameter, charged with powder, and fired by a fuse, or by percussion-caps placed on nipples paojecting from the surface. It is thrown by the hand from the parapet of a fortrees, among soldiers advancing to the assault along the

#### Greyhound

covered way and across the ditch. Grenades are also thrown into the trenches when the approaches are driven close to the main works.

driven close to the main works.

GERNADIER, gren-id-deer', the name formerly given
to any soldier belonging to the infantry or cavalry who
carried granades. Granadiers were introduced into
the French service in 1667, and into the English service by Charles II., about 1634. They were armed with
muskets, swords, pouches containing granades, and
hatchets, and took the lead in the assault of a fortress. At first only two men were selected and trained as grenadiers from each company of the two English regiments of foot-guards that were then in the service; but shortly after there were two companies of grenadiers to each of these regiments, while horse grenadiers were attached to the regiments of life-guards and horse granad. diers were attached to the regiments of life-guards and horse-guards. Until a few years ago, a grandier company, consisting of the tallest men in the battalion, formed a part of every regiment of infantry, which took the right when the regiment was in line, and marched first when in column. They were distinguished by wearing bear-skin caps, and shells with fire issuing from them on the collar of the tunic; but they were armed with a rifle and bayonst, like the rest of the regiment; and although they retained the name, they did not perform the duties that were originally assigned to green diers.

to grenadiers.

GERTNA GEEEN MARRIAGES, gret'-na, is the name given GRETA GREEN MARHIAGES, gret'-m, is the name given to a class of irregular marriages which were formerly very common, and took their name from the village of Gretna Green, on the borders of Scotland. They originated in the greater laxity admitted by the law of Scotland than by that of England, on the subject of marriage. In Scotland, a marriage may be contracted by a mutual declaration to that effect by the two parties in the presence of witnesses, a mode which is much more simple and expeditious than that of England; and hence it was largely taken advantage of by runaway couples from England; the rule being, that a marriago is valid in England if contracted according to the law of the place in which it was solemnized. Cretna Green of the place in which it was solemnized. Gretna Green of the place in which it was solemnized. Greens Green being the most convenient place on Scotol ground for parties from England, the marriages usually took place there; but they were also celebrated at Spring-field, Annan, Coldstream, and other places along the border. At Greens Green and the other places there were usually one or more persons who took upon themselves the attitude of the prices to add in the content. were usually one or more persons who took upon themselves the duties of the priest, and in whose presence the declaration was made. The marriage service of the Church of England was sometimes read, in order to please the parties. The practice is said to have been begun at Greens Green rather more than a century ago, by a person named Paisley, a tobacconist. Afterwards it was carried on by various individuals, each inn, in fact, having its rival priest, besides various others, who carried on the business on their own account. Latterly, the best-known of these worthies was a blacksmith, though he is said to have had a formidable rival in a person who was employed in breakwas a blacksmith, though he is said to have had a for-midable rival in a person who was employed in break-ing stones on the roadside, and who in this way had the advantage of getting the first word of the parties in passing. Though sometimes large sums were received, the effect of competition had been to reduce the fee, in some cases, as low as half a crown. The marriages effected in this way were at one time esti-mated as high as 500 a year. The practice, however, has virtually been put a stop to by 19 & 20 Vict. c. 96, which declares that no valid marriage can be conwhich declares that no valid marriage can be con-tracted in Scotland, unless one of the parties had, at the date thereof, his or her usual place of residence there, or had lived in Scotland for twenty-one days next preceding such marriage

GREY FRIARS. (See FRANCISCANS.)

GREYHOUND, gray'-hownd (Ang.-Sax.), (Canis grains), a species of dog used for the chase, which appears to have been known even in the most remote ages of anhave been known even in the most remote ages of antiquity, as it is represented on some of the oldest of Egyptian monuments. Its first portraiture that can be relied on is in a painting on one of the tombs of the fourth dynasty of Egypt, which must be upwards of 4,000 years old. The cultivated English greyhound, according to Blaine's "Encyclopedia of Rural Sports," exhibits a model of elegance, and a combination of symmetrical proportions probably unrivalled by any other animal but the race-horse; and the perfection

974

#### Griss

of the mechanism for speedy progression is apparent throughout its structure. As the greyhound hunts by sight rather time by smell, its eyes are placed more conspicuously forward than in other dogs. The head is beautifully shaped, and slender in proportion; its muzzle is long and pointed; the ears droop at the points; the back is broad and muscular; the hold being lank and very much contracted in its body being lank, and very much contracted in its lower parts. The legs are long and muscular, while the thest is capacious and deep, with the tail slender and

GREYHOUND.

curved upwards at the end. The Irish greyhound, or wolf-dog, is a variety of this animal: it is stronger and larger, but it is not so fit for hunting purposes, as it lacks the speed and keen eyesight of the true greyhound. The Italian greyhound is a much smaller variety than the English, and is a very delicate animal. From its diminutive form and tender constitution, it is more fit for the duties of a lapdog than for those of the chase.—Ref. Blaine's Encyclopædia of Rurul

Sports.

GMAS, gri'-as, a gen. of plants belonging to the nat. ord. Myrtacea, natives of Jamaica. The tube of the calyx adheres to the ovarium; the limb is small, 4-cleft, and obtuse; four petals, coriaceous; numerons stamens, inserted in a square diac; the filaments joined at the base into a series of five, the minor ones being very short; the anthers small and kidney-shaped; the style wanting; the stigma cruciate and hidden in the curved stamens; the fruit ovate, 8-furrowed, and crowned by the culyx. There is only one species, the G. cauliflora, or anchovy pear. In appearance it is a tall tree, with small branches, very long oblong leaves, and large white flowers, placed on long oblong leaves, and large white flowers, placed on short many-flowered peduncles. It generally grows in boggy places, and its fruit is an ovate, being as in boggy places, and its fruit is an ovate, being as large as an alligator's egg, and of a brownish usset colour. This fruit is pickled, and eaten in the same way as a mango. The anchory pear is easily propagated by seed, and the young plants must be kept in a moist heat. It may also be propagated by large cuttings placed under glass in heat; and a loamy soil is last suited to its course.

cuttings placed under glass in heat; and a loamy son is lest suited to its growth.

GRIFFIN, griffin, or GRYPHON (Fr. griffon, Lat. gryphus), in ancient Myth., a fabulous animal, supposed to be generated between a lion and an eagle. It is represented with four legs, wings, and a beak; the upper part resembling an eagle, and the lower having the characteristics of a lion. This imaginary animal was supposed to watch over gold-mines and all hidden treasures, and was consecrated to the sun, where having some of the ancient vainters represent whose chariot some of the ancient painters represent whose charlot some of the ancient painters represent as drawn by griffins. Spanheim states that both the chariots of Nemesis and Jupiter were likewise provided with similar steeds. The griffin is found on many old medals, and it seems to have been a principal ornament. On the provided with a specific seems of the principal ornament of the principal ornament. nectus, and a seems to have over a principal ornament of Grecian architecture. In heraldry, the griffin is the symbol of strength, swiffness, courage, and vigilance, and it thus finds a place on many escutcheons: it is usually biazoned rampant, although occasionally segret-

#### Grinding-Mill

ant is thought to be its proper position. The griffin, mentioned cometimes in Scripture, was a species of

mentioned cometimes in Soripture, was a species of eagle, called by the Latins ossifruga, or osprey.

GRINDING-MACRINE.—A finely-executed piece of machinery, by Messrs. Nasmyth, Gasked, & Co., has been invented to grind up the faces of the different parts of machinery when a large surface is required to be made perfectly smooth. At figs. 1, 2, and 3 are shown severally a side elevation, an end elevation, and a plan of a double-face grinding-machine, the one side being a repetition of the other. To the wo exterious frames, a pare holded two large plummer. two cast-iron frames a,a are bolted two large plummer-blocks for carrying the main shaft, having at each extremity the circular frames divided into twelve comextremity the circular frames divided into twelve compartments, in which are placed the grinding-stones f, each being adjustable by the small set acrews m round its circumference. On the top of the cross-frames a are placed two longitudinal frames (b, b), made also of cast iron, for supporting the long bed-frames c, c, c and also the self-acting apparatus farnished to this machine. Two motions, the one at right angles to the other, are given by the slides d, working along the beds c, and also the face-plates e for carrying the work, by which it is brought into contact with the grinding-stones. Pits are made to allow the wheels for carrying the stones to work in. The self-acting motion given to the work being faced, by means of which it slides along the bed c, while the grinding-stones are revolving in their ares, is obtained in this manner: on the main shaft next to the driving-riggers, or pulleys g, is a worm (f), which, as it revolves, works a worm-wheel, represented by the dotted lines in fig. 2, thus communicating the motion to the upright spindle; from this it is carried by the to the upright spindle; from this it is carried by the bevel-wheels to the spindle running horizontally the whole length of the machine, having at each extremity three small bevel-wheels. The action of this apparatus is thus:—Supposing the slide to be travelling in the direction towards the small bevel-wheels, two of the direction towards the small bevel-wheels, two of which are required for the purpose, while the third, or outer one, runs freely on the spindle without producing any effect, the small clutch being disengaged from it; on the travelling slide d is fixed a stud or pin (h'); a long rod (k), of the same length as the bed c, is movable in two stud-bearings fixed to it. As the slide d travels, the pin h' comes in contact with a second stud, or pin, adjusted to any position on the rod h, according to the length of the motion required, which must naturally press it forward, and thereby which must naturally press to that, and the blow out the clutch on the end of the spindle, which, being shifted from one bevel-wheel to the other, disengages that which had been at work before, while it engages the outer one, that had been running loosely on the spindle: by this curious contrivance the screw for working the slide revolves in a contrary direction, and instead of drawing the slide d towards it, sends it and instead of drawing the side a towards it, sends to back. A counterbalance weight (n) is connected to the extremity of the rod h, whereby the work is advanced to the face of the grinding-stone; it is on the upper part of the slide ethat the work is fixed. A substantial foundation, consisting of stonework, is prepared for receiving the two frames a, a, and to which they are firmly bolted down by strong holding-bolts. Another mode of performing this same operation might be adopted by fastening a whole grindstone into the chucks, and passing a bolt through two surface-plates of two feet diameter each, one on the middle plates of two feet diameter each, one on the middle part of each face of the grindstone, he which means they would be more effectually secured in their places. We annex a complete list of the references to the figures. a, cross-frames, or standards; b, longitudinal frames; c, bed-plates; d, cross-sides; s, slides, or face-plates, for carrying work; f, grindstones; g, driving-riggers; h, rods for reversing motion by means of tappet h' and clutches i, s, clutches; j, bevel-wheels it, worm on main shaft for working bevelgeer j; m, screws for setting stones; n, counter-balance weights. balance weights.

GRINDING-MILL.—A valuable invention, by Mr. Bogardus, of New York, is shown in the annexed engraving. The advantages of this eccentric grinding-mill are:—1. The peculiar motion of the plates will of itself discharge ground substances, so that many substances can be ground thereby which would altogether

twice the distance of the centres of the plates, thereby rendering the wear-and -tear of the plates uniform, and preserving the grinding action of every point. 3. tum, India-rubber, flax-seed, oil-cake, &c. Of the luckers with its distance from the centre; but in this by other mills; in short the eccentric mills are more

by other mills; in short the eccentric mills are more economical in the power required to drive them, and mill, every point from the centre to the circumference economical in the power required to drive them, and has the same grinding power. A considerably smaller in the labour of tending them; they are less costly for mill will, therefore, effect a given purpose, and the the work they do, and more portable; they are capa-

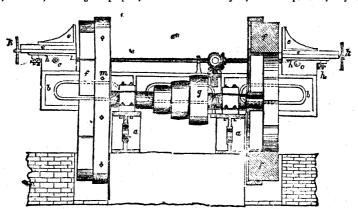

Fig. 2 .- END ELEVATION.

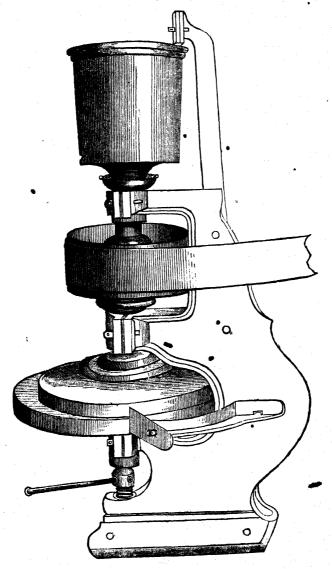

eccentric mill is therefore more portable than other mills. A. The ever-changing action of the mill, and the quick discharge of the substance ground, prevent it from becoming heated, so that the eccentric mill may be profitably employed in grinding substances, which, in other mills, would be either spoiled or deteriorated in quality, or, by their melting, be impossible to be ground. If other mills were driven with that speed which can be safely applied to the eccentric mill, they would be made red-hot in a few minutes. These mills have been successfully introduced for the follow-

ble of being applied to purposes for which other mills are useless; and the wear-and-tear is trifling. The mill should run to the right, and make not less than three hundred revolutions per minute. Nearly any quantity can be ground by increasing the speed. The mill is regulated to grind fine and coarse by the underscrew on which the end of the shaft revolves: turning the screw to the left will bring the plates together and cause the mill to grind finer. The regulating screw is held firmly in any position by a small screw placed against its side. There are three reservoirs, which

# Grinding-Mill

# Grinding-Mill

should be well supplied with oil. The first is on the top of the upper plate two or three tablespoonfuls of oil should be poured into this reservoir through a small hole made in the top of the mill for that purpose. The second reservoir is the box through which the main

THE BOGARDUS GRINDING-MILL.

shaft passes: this is just under the spout of the mill.

This reservoir is filled with tallow, so that it may supply itself. The third reservoir is the step in which the ply itself. The third reservoir is the step in which the main shaft revolves: that may be filled with oil. The main shaft revolves: that may be filled with oil. The feeding is regulated by a shoe acting against the tabe of the upper plate, which causes the shoe to vibrate:

#### Grindstone

the lower separate revolving plate at a distance from it, to suit the nature of the material to be ground. The centre of motion of the latter plate is placed about an unce out of the centre of the upper one; it is driven merely by friction generated by the abrasion of the abrasion of the substances in process of grinding between the plates. An adjusting screw, F, is placed beneath the lower plate, for the purpose of setting the latter at the transport of the stone of t

#### Griseldia

im size according to the purpose for which they are intended. In grinding to a smooth surface large away, axes, scythes, swords, and all heavy cutlery, heavy stones are used, weighing sometimes from two to three tons; these are secured on wrought-iron shafts, and the workman applies his weight to the article on the stone. Grindstones, or grit-stones, are almost entirely composed of sandstone, and are obtained from the sandstones and willstone arise of the scel-

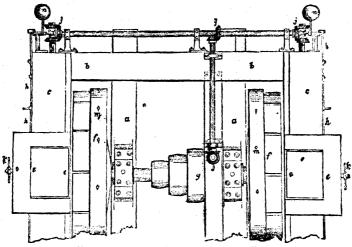

Fig. 3. DOUBLE-FACE GRINDING-MACRINE-PLAN.

form of grinding-mill is that used in Mexico, called Arrastre, or Tahona. It is extensively employed in the mining districts of Mexico for grinding silver ores the mining districts of Mexico for grinding silver ores previous to their amalgamation. It consists of a strong wooden axle, moving on a spindle in a beam above it, and resting on an iron pivot beneath, turning in an iron bearing, which is inserted into a post wood, which rises about a foot above the ground, in the centre of the arrastre. The shaft is croxed at right angles by two strong spars, which form four arms, each about five feet long one excented which is 9 feet angree by two strong spars, which form four arms, each about five feet long, one accepted, which is 9 feet long, to admit of two mules being attached to it: by this arm the machine is worked. The grinding is performed by four large porphyritio or basaltic stones. These are loosely attached by thongs of leather or and larged work for the four arms and arms. small-sized rope to the four arms, and are dragged round over the ore, which is put in with water until its ground to a very fine slifte, or mud, called the lama. One of these machines, when in good working condition, will grind from 600 to 800 lb. of ore in twenty-four hours. In Guanaxnato, where the best and finest grinding is obtained in the arrastres, the lining and foundation, and the grinding-stones, are, of course, grained porphyry, and form a rough surface. The cost of this apparatus in Mexico, including the paving of the bottom and the four metuniles, or stones, is on an average 27. The original small-sized rope to the four arms, and are dragged ciuding the paving of the bottom and the four meta-piles, or stones, is on an average £7. The original weight of a metapile is about 700 lb.; its dimen-sions are 2 feet 8 inches long, 18 inches broad, and 18 inches deep. Notwithstanding the hardness of the stones employed, they are so worn as to become un-serviceable in the course of ten or twelve weeks; the bottsex, however, is only replaced once in twelve serviceable in the course of ten or twelve weeks; the botters, however, is only replaced once in twelve months. A drawing of this curious machine is given in Ure's Dictionary of Arts, Manufactures, and Mines, vol. ii. p. 536. From the same authority we have borrowed the above description.

GRENDSTONE, grind'stone, a well-known tool used in aimest every branch of the mechanical arts for grinding to an edge, piont, or face, the various tools and in manufacturing; and also in various manufactures for reducing metallic surfaces, such as the main of steel implements, &c, Grindstones vary

measures. They are split out of the quarry by wedges, and dressed on the sides by chisel and ham mer. A square hole, in proportion to the weight, is cut in the centre; the face is then chipped down, as nearly as possible to its intended circumference, and sent to market. After mounting and wedging the stone upon its arle, it is chipped off at the prominent points and then turned. The heavy stones, in particular, require great care in the hanging and trimming, that they may run smoothly. The best-known varieties of grindstone are, according to Mr. Knight, the following:—the Newcastle grindstones, which abound in the coal districts of Northumberland, Durham, Yorkshire, and Derbyshire. They are selected of different degrees of density or coarseness, according to the work they are intended to perform. A similar de-scription of stone is that called the Bilston grindstone, which is a stone of great excellence, light in colour, and of a fine, sharp texture, without being too hard. It is only to be obtained from a very limited area in or near Bilaton, in Staffordshire, where it overlies the The Wickersley grindstones are obtained from a village about nine miles east of Sheffield. These stones are much used for the finer kinds of edge tools. tones are much used for the informatics of edge tools. The Sheffield grindstone is a hard, coarse grit-stone, which is obtained from Hudsley, about fourteen miles north of Sheffield; it is used for grinding large files and similar tools. The Devonshire batts come from near Columpton. Yorkshire and Congleton grit are other binds of grindstone. The Devonters are contacted from the state of the other kinds of grindstone. The Burr stones are well known, and bear a high character; they come from known, and hear a high character; they come from La Ferte-sous-Jouarre, in the department of the Seine-et-Marne, France. For grist-mills they have been pronounced as of unequalled value. The com-bined roughness and hardness of this tertiary quartz endow it with immense advantages. The stones formed of this rock are in general pieced, which

renders them very expensive.

GRIERLDIS, gris-el'-dis, is the name of the heroine of a popular tale of the middle ages, originally apparently Italian, but which was subsequently adopted by various other nations. She was originally a poor charcoal-burner, whom the Marquis Walter of Saluzzo took to

#### Grist-Mill

wife, and then put her humility and obedience to the hardest tests; but having victoriously withstood them all, a reconciliation took place. As a tale, said to have an historical foundation, we first meet with it in Boc-caccio's Decameron (z. 10). It was translated into Latin by Petrarch in 1373, and in the 15th century it

Latin by Petrarch in 1373, and in the 15th century it was well known in Germany. It was dramatized in Paris in 1398, in England 1599, and in Germany, by Huns Sachs, in 1546.—Ref. Conversations Lexikons. GRHEL-MILL.—A most ingenious form of machine for trinding grist has been invented in the United States by Mr. Ass Barber. It is capable of grinding corn in the ear, and can also grind all other kinds of capin and although the protest critical states. orn in the ear, and can also grind all other kinds of grain; and, although it has metal grinders, never requiring to be sharpened. It is so constructed, and the cooling surfaces so arranged, that the grain is not heated. By a 2-horse power it is capable of grinding from eight to ten bushels per hour. The accompanying figures show all the details of this very useful machine:

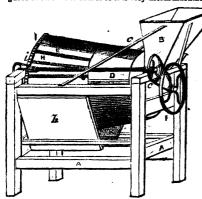

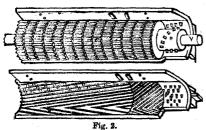

Fig. 1.

—A A is the frame; B is the hopper; C are stays connected with the longitudinal beam of the frame supporting the hopper; B is a large revolving cylinder; covered with a wire cloth for botting; F is a fly-wheel; G is a band-wheel, or pulley, driven by a band from the main driver, to propel the shaft H, which has a small pinion on it meshing into cogs, or a large cogrim (1) of the large cylinder E; J is a small pulley on H, which drives by a band the shaft (not seen) of an interior scraper; K K are two angular boards to

guide the ground meal into the granary. This is a sectional view, and does not show all the interior, but merely the grinding surfaces. B is a revolving iron grooved collar made of a series of cast grooved rings, secured to the shaft. This shaft is made to sit and reculve in O, a concave iron grooved bed, which is a stationary; D is a shoulder, with teeth to grind the cob as it leaves the hopper, before being submitted to the operation of the revolving roller B. Suppose these two sections to be placed in the inside of E, with B revolving above and in the concave bed O; now the grain enters in the hopper, and the revolving is a ground-rent payable out of the ground before the 978

#### Ground Annual

roller being set in motion, it will easily be perceived that the grain will be carried into and between the roller and the bed, and discharged through the channels or grooves on C. Still the meal thus ground has to be bolted. This is done in the most simple manner: to be bolted. This is done in the most simple manner: as E is revolving, the fine meal falls through the belting-cloth at the bottom, and the coarse is carried round, and falls down into the mill, to be ground over again. By this way of grinding, the revolving grinder and the bed need not be in such close contact as other grinding, mills must be; and the huge revolving surface of E keeps perfectly cool, and allows the arterior of the mill, to be quite over in the attention of the mill, to be quite over in the attention. revolving surface of E keeps perfectly cool, and allows the exterior of the mill to be quite open to the atmosphere. There is a scraper, which is revolved by the band-frame I, at the right of fig. 2, which keeps the grooves of the roller or bed from getting clogged.

GROAT, grawt (Du. groot), a silver coin once current in England, equal in value to four-ence of our present money. It was introduced by Edward III., about 1351, and has been revived in our modern four-enny views (1835). though the name is not

fourpenny piece (1835), though the name is not

fourpenny piece (1835), though the name is not retained.
GROATS (Ger. grutse), oats divested of the integriments or hulls. They are used for making grael: when crushed, they constitute the Embden and prepared groats of the shops. (See Avena.)
(Seo Avena.)
(Seo Avena.)
(Hood, groom (from Flem. groom), the name of a servant in some inferior place, generally applied to servants in stables; but it has a special signification as applied to the groom of the chamber, groom of the stole, &c. The groom of the chamber, groom of the stole is a great officer of the royal household, who has control over all the duties pertaining to the bedchamber (the only portion of the royal chambers wherein the lord chamberlain has no authority). He does not take any fixed turn of duty, but attends only on state occasions. Slole signifies a robe of honour.
GROSBBAK, grose-beek (Coccobraustes), a bird

state occasions. Stole signifies a robe of honour.

GROSBRAK, gross-beck (Coccothraustes), a bird which comes under the general hest of Fringillida, in the sections of Insessores, Conirostres. The characteristics of the class are given under Fringillida, to which the reader is referred. There are several varieties; as the hawfinch grosbeak (Coccothraustes vulgarie), the pine grosbeak (Lowis enucleator), and the green grosbeak, which is treated under the head of Chernymone (which see). The hawthorn grosbeak, or hawfinch, however, will suffice to describe the appearance of the bird, as between it and the others there is little difference. The hawthorn grosbeak, or common grosbeak, inhabits England, France, some parts of Italy, Germany, Sweden, and even the south of Russia. The varieties in the colour of this bird are white, yellowish-grey, and grey; the wings and tails are

of Russis. The varieties in the control of this had white, yellowish-grey, and grey; the wings and tails are often white, and the plumage generally partakes of that colour. The grosbeak inhabits the woods in summer, and in the winter generally makes its appearance in towns and villages. The nest, which the female builds, is towns and villages. The nest, which the female builds, is one of the prettiest kind, being coloured and decorated with all kinds of brillantly-tinted mosses, and lined inside with down and feathers. The eggs are of a bluishgreen colour, with brown spots. The bird is generally about seven inches long; it has no song worthy of notice, and is not a common bird with us, although it is to be met with in England. (See FRIN VILLIDE.)

Gross, gross (from Fr. gros), in Com., b, which certain things are reckoned, is twelve dozen.

GROSSULARIAGEE., gros'-st-lit-re-ord feet. (Lat. grossula, a gooseberry), in Bot, the Gooseberry or Current fam., a nat. ord. of Diccipledones, sub-class Calgojfora, consisting of shrubs, natives of the temperate regions of Europe, Asia, and North America. Some of the species have spines or prickles. The leaves are alternate, lobed, and radiate-veined. The flowers are arilary, racemose, perfect, or rarely unisexual; with superior

lobed, and radiate-veined. The flowers are axillary, racemose, perfect, or rarely unisexual; with superior calyx 4—5 lobed; five minute petals inserted the calyx; five stamens alternate with the petals, and inserted in the same manner; and an inferior 1-celled overy, with two parietal placentss. The fruit is pulpy, with numerous seeds. There are but two genera and 95 species. Some are showy garden plants; but they are mostly remarkable for their agreeable acid fruits, known as gooseberries, and red, white, and black currants. (See Ribbs.)

GROUND-RENT, in Law, is a periodical payment for the privilege of building on another's land.

the privilege of building on another's land.

GROUNDELL. (See BENECLO)

GROUND, growse (Ang.-Sax.), a species of game bird which belongs to the family of the Tetraonida. The bill is rather short, broad at the base, compressed and arched, with the tip obtuse, the nostrils being placed at the base of the bill, and proteoted with feathers, or a hard scally substance; the legs are stout, with the tarei naked and scutellate, but sometimes covered with feathers to the toes; the hind toe, which is rarely wanting, is rather small and elevated, the wings abort and rounded, and the tail also rounded at the extremity. These birds live chiefly on the ground, on which they can run with great swiftness, and they feed principally on vegetable substances, such as berries, seeds, and the buds of trees and shrubs. They vary greatly in size, some being nearly as large as a turkey, while others scarcely exceed a pigeon in size. There are several varieties of the grouse. The most important bird of this class is called the capercalizie, or wood grouse. (See Capencaltzie). To speak correctly, however, the black-cock (Tetrao tetrix) is one of the largest species of grouse which can be termed truly British, as it is found both in England, Scotland, and Ireland. The form of the tail is one of the most peculiar features in this bird, as the four outer feathers are considerably elongated and curred outwardly at the tip, so that the tail has the appearance of a double hook. In its habits and other characteristics, the black-cock strongly resembles the caper-calizie. The common grouse, or ptarmigan (Lagopus) GROUNDSEL. (See SENECIO.) ties, the black-cock strongly resembles the caper-cailzie. The common grouse, or ptarmigan (Lagopus vulgaris), is another variety of this species, and the feathers of this bird extend to the very extremity of the toe. Like the preceding classes, it feeds on ber-ries and the small shoots of plants; and, unlike them, it is not polygamous, the males and females pairing regularly in the breeding season. The red grouse (Lagopus scoticus) is peculiar to these islands, and inhabits all heathy districts, whether lowland or mountainous; whilst the ptarmigan (Lagons vulgaris) only inhabits very hilly countries, as the northern parts of Europe and the mountainous regions of Spain and The red grouse is the same colour in plumage Italy. The red grouse is the same colour in pummar all the year round, whilst the ptarmigan acquires a white habit in the winter months. The grd grouse is a most prolific bird, and it is wonderful how it can be a most prolific bird, and it is considered to the wonderful how it can be a most prolific bird, and it is considered to the wonderful how it is considered. a most profine bird, and it is wonderful how it can exist in such large numbers, when it is considered what quantities are shot every season to supply the London market between the months of August and

GRUB, grub (Ang.-Sax.), a small worm: it is a name however, more properly applied to the hexapod worms produced from the eggs of beetles, &c., which are eventually transformed into winged insects. (For fur-

ther information, see Pupl.)
Grus, grus (Lat. grus, a crane), the name of one of Bayer's constellations in the southern hemisphere, between Eridanus and Sagittarius. It has no stars of the first or second magnitude.

GRYPHOSIS, gri-fo'-sis (Gr., from grupoein, to incurvate), in Suze, is a disease of the nails, which turn inwards, and invitate the soft parts below.

nuwards, and nutrate the soft parts below.

Gualacum, gwai'-yā-kum (fr. guayac, its native name),
a gen. of the nat. ord. Zygophyllaceae. The species
G. officinale is a fine evergreen tree from 40 to 60 feet
in height, and of a dark, gloomy aspect. It is a native
of the West-India islands, particularly Cuba, St.
Domingo, and the south side of Jamaica. The wood
is remarkable for its hardness toucheast and is remarkable for its hardness, toughness, and dura-bility, qualities which render it particularly valuable for many purposes. It is known in commerce as lig-num vites. This wood, and a resin obtained from it, for many purposes. At is known in commerce as any num vite. This wood, and a reein obtained from it, are officinal in our pharmacopecias, and are commonly known in the shops respectively as guaiacum-wood and guaiacum-resin. The latter is generally procured by heating the wood, either by boiling chips in salt water, or more commonly by burning kollow billets, and hing the resin as it flows out from thom. It also

#### Guano

the wood and resin are used as stimulants, disphoretics, and alteratives, chiefly in gout and Theumatism, and also in syphilitic and various cutaneous affections. G. sanctum, a native of Porto Rico, and G. arboreum, the guayacan of Cumana and Carthagena, are said to

gusyacan of Cumana and Carthagena, are said to yield some of the lignum vite of commerce.

GUALTHERIA, gwill-the're-id, in Bot., a gen. of the nat. ord. Ericara. (The species G. procumbens is a native of North America, and is commonly known as the partridge-berry. Its leaves possess aromatic, astringent, and attimulant properties, which they owe to the presence of a volatile oil and tannin. The oil is known in commerce under the names of oil of partridge-berry and oil of winter-green. An infusion of the leaves is employed in certain parts of North America as a substitute for China tes, and is called Mountain or

Salvador tea.

Substitute for Chma tes, and is called Mountain or Guano, gu-àn'-o (from the Peruvian word kuano, dung), the excrement of sea-fowls, found principally in large quantities upon some parts of the coasts of Peru, Bolivis, and Africa. Although of comparatively recent use in this country, guano has been employed as manure by the inhabitants of Peru from the most remote periods. By its means they have been able to reuder fertile the otherwise unproductive sandy soils along the coast. While the Incas governed the country, the birds were protected from violence by very severe laws. Any one landing on the guano-bearing islands during the period when the birds were breeding, was put to death; and a similar sentence was decreed against those who killed any of the birds at any time. Baron Humboldt first brought specimens of guano to Europe in 1804, and sent them, for examination, to Fourcroy, Vauquelin, and Klaproth,—the best analytical chemists of the day. He thus described it:—"The guano is deposited in layers of 50 or 60 feet thick, upon the granito of many of the South-Sea islands off the coast of Peru. During 200 years the coast birds have deposited guano only a 300 years the coast birds have deposited guano only a few lines in thickness. This shows how great must have been the number of birds, and how many cenlew lines in thickness. This shows how great must have been the number of birds, and how many centuries must have passed over in order to form the present guano-beds." There seem to be three varieties of guano in Peru: the white, grey, and red. The red is the oldest deposit, and the white the most recent. Bones and festiners of birds, together with crystalline deposits, are found amongst the layers of excrement. A large portion of the so-called Peruvian guano is imported from the Chincha islands. These islands, which are three in number, are respectively about five or six miles in circumference, composed of granite, and covered with guano, in some places to a height of 200 feet. No earthy matter is ruixed with this great accumulation of excrement. During the last few years, the export of guano has increased considerably. Between 300,000 and 400,000 tons are the annual amount at present. A large number of men, many of whom are Chinese, are employed to remove the guano to the ships. They work their way through the mass with pickaxes, and leave a sort of wall on either side. It is then removed in wheel-barrows, either direct to the mouths of the shoots at barrows, either direct to the mouths of the shoots at the edge of the cliff, or to the house waggous running on tramways for the same purpose. With regard to the operation of guano as a manure, there has always been a good deal of discrepancy in the statements put forth as to its operation. There can, however, he little doubt that it is a very efficient manure. Its operation in Peru is seen in the conversion of the sandy desert near Lima into a soil capable of bearing large crops of maize. The Peruvians have a proverb concerning it, which sfillrms that "Huano, though no saint, works many mirscles." There are several commercial varieties of guano, the principal of which are
—Peruvian, Angamos, Ichaboe, Patagonian, Saldanha
Bay, Kooria Mooria, African, and Indian. In chemical
analysis, guano shows that one of the most, if not the most, important of its constituents is ammonia: some varieties contain from 17 to 20 per cent. Guano also contains potash and a considerable quantity of chloride ing the wood, either by boiling chips in salt water, of sodium (common salt). Next to the ammonia, the more commonly by burning kollow billets, and phosphoric acid seems to hold the place of importance, hing the resin as it flows out from them. It also the tree is cut or wounded in any way. Both the tree is cut or wounded in any way. Both cent. Good guano, when analyzed, is found to contain

#### Guarana

about 50 per cent. of ash or mineral substances, and 50 per cent. of combustible or organic matters. Good Peruvian guano is worth from £12 to £14 per ton. It is largely adulterated with umber, finely-ground stone, old mortar, and partially-decomposed sawdust. Instances have occurred when adulterating substances

Brances have occurred when admerating substances have been present in the proportion of 87 per cent.
GUARANA, or BRAZILIAN COCOA. (See PAULLINIA.)
GUARANTER, or GUARANTY, gar-rin-te (from Fr. garantir, to warrant), is a promise, or undertaking, to be responsible for the debts or duties of a third party, be responsible for the debts or duties of a third party, in the event of his failing to fulfill his engagement. To make such an obligation binding, there must be some good consideration moving from the party with whom it is made; as the delivery of goods to, or work to be done on credit for, the person on whose behalf the guaranty is given. It must be in respect of a contemporaneous, or future debt or act. If a guaranty be rude in respect of a debt blandy incurred these made in respect of a debt already incurred, there must be a new consideration to support it. A consimust be a new consucration to support it. A consideration, however, need not be expressed; for if it can be fairly implied from the circumstances, or the language used, it will ordinarily be sufficient. It is sufficient if the person for whom it is given receive a benefit, or to whom it is given receive, or may receive, a detriment. The Statute of Frauds enacts that a defendant cannot be charged to answer for the debt, default, or miscarriage of another person upon any special promise, uffices the agreement upon which such action shall be brought, or some memorandum or such action shall be brought, or some memorandum or note thereof, shall be in writing, and signed by the party charged therewith, or some other person duly authorized by him. This statute only applies, how-ever, to engagements in which the guarantor is only liable conditionally upon the default of some other person: where he is liable coextensively with the other

person: where he is liable coextensively with the other party in the first instance, it does not apply.

GUARD, gard (Ang.-Nor.), in Mil., the name applied to a body of soldiers charged with the care of prisoners, or the protection of baggage and military stores. A guard is always stationed at the entrance to a fortified town, citadel, or barracks. The number of men of which a guard is composed differs according to the rank of the officer, or non-commissioned officer, by whom it is commanded, or the purpose for which it is designed. There is always a room or separate building. party in the first instance, it does not apply.

Guer, gard (Ang. Nor.), in Mil., the name applied to a body of soldiers charged with the care of prisoners, or the protection of baggage and military stores. A guard is always stationed at the entrance to a fortified town, citadel, or barracks. The number of which a guard is composed differs according to the rank of the officer, or non-commissioned officer, by the rank of the officer, or non-commissioned officer, by set apart for the accommodation and protection of the set apart for the accommodation and protection of the guard, the men taking it in turn to perform the duties white, and the tail forked. The gudgeon swims in of sentry outside. When the general in command is passing, and on similar occasions, the whole guard is afford grest sport to anglers, from their greediness in passing, and on similar occasions, the whole guard is passing, and on similar occasions, we wante generally turned out and presents arms. A guard of hotour is a detachment on duty on special occasions, as a token of respect. The regiments which precede or follow an army or division on the march, at a short distance, are called the van-guard and rear-guard respectively. the old coaching days, a man known by this name always accompanied a coach, and was generally armed, for the better protection of the mails and articles of value. Every railway train is under the charge of one or two guards, who see that the time between station and station is correctly kept, and look to the safety of

and station is correctly kept, and to be savely or goods and luggage, and the requirements of passengers.

Guardian, gar-de-an (Fr. gardien), in Law, is one who has the care of the person and property of a minor, who is called his ward. He performs the office of both tutor and curator in the Roman law; the former having the charge of the maintenance and education of the minor, the latter the care of his fortune. Of the several species of guardians, the first are guardians by nature, namely, the father, and in some cases the mother of the child; for if an estate be left to an infant, the father is by common law the guardian, and must account to his child for the profits. There are also guardians for nurture, which are of course the father and mother, till the infant attains the age of fourteen years; and in default of father or mother, the

#### Guebers

The guardianship in socage ends when the minor attains the age of fourteen, when he may appoint his own guardian. Guardians by statute, or testamentary guardians, are such as are appointed in virtue of the statute 12 Car. II. c. 24, confirmed by 1 Vict. c. 26, which ensets that any father under age, or of full age, may by deed or will, attested by two winesses, appoint any person or persons (except a popish recusant), as may by deed or will, attested by two winesses, appoint any person or persons (except a popish recusant), as guardians of their children, either born or unborn, until they attain the age of one-and-twenty years. There are also special guardians by custom in certain places, as in London the guardianship of orphans under age and unmarried belongs to the city. The guardian is considered as a trustee for his ward, and is accountable for the due management of the infant's property, and is answerable not only for fraud, but for negligence or omission. Guardianship in chivalry, which was abolished by 12 Car. II. c. 24, was a part of the ancient foudal system, the lord being entitled to the wardship of the heir, if a male, until the age of twenty-one, or if a female, until fourteen. This wardship consisted in having the custody of the body and lands of such heir, without any account of the profits during that time. without any account of the profits during that time. If the female remained unmarried after fourteen, the lord might keep her in wardship till ahe was exteen, in terms of the statute of Westminster I., 3 Edw. I. c. 22. This guardianship being considered a property, rather than a trust, was saleable, and if not disposed of, passed than a trust, was saleable, and if not disposed of, passed at the lord's death to his personal representatives. Guardian of the spiritualities, is the person to whom the spiritual jurisdiction of any dioceae is committed during the vacaucy of the see; while the guardian of the temporalities is he to whom the temporal jurisdiction and profits of the see are committed during the like period. Guardians of the poor are certain persons appointed in a parish, or union of parishes, to act in lieu of overseers, and to superintend all matters relative to the relief and unpreparent of the poor. (See POOR LAWS)

Shoals, and feeds on worms and aquatic insects. They afford greeff sport to anglers, from their greediness in seizing upon any bait presented to them. They spawn in May, generally in shallow water, to which they repair for the purpose.

Guerre, Gherre, or Gavers, gwai'-bers (i. e. giaours, dogs, infidels), is a term applied by the Mohammedan conquerors of Persia to the disciples of Zoroaster in that country. They call themselves "Behendies," i. e., followers of the true faith, and are generally known by Europeans as fire-worshippers. Zoroaster is believed to have flourished in the 6th century B.C. In course of time the system became very tury B.C. In course of time the system became very corrupted, and King Ardeshir Babekan (a.D. 226) reformed it, collected the sacred books, and caused them to be translated from the Zend language into the mem to be translated from the Zend language into the vernacular dialect of Persia, and built temples for the preservation of the sacred fire. Under the Mohammedan invaders in the 7th century, they were much persecuted, and most of them embraced Islamian. A small rammant, who clung to their old faith, were finally allowed to settle in one of the most barren parts of the kindow. of the kingdom. They now number about 100,000 souls, dwelling chiefly in the city of Yezd and the province of Kerman. They have the character of being of the kingdom. industrious and virtuous, in comparison with the other Persians, but they are ignorant and depressed. A body of the Guebres left Persia at the time of the fourteen years; and in default of father or mother, the ordinary usually assigns some discrete person to take are of the infant's personal estate, and to provide for his maintenance and education. Guardians in socage take place only when the minor is entitled to some estate in lands, and then by the common law the guardianship devolves upon his next of kin, to whom the inheritance cannot possibly descend, for the law infant in judges it improper to trust the person of an infant in judges it improper to trust the person of an infant in sands who may by pssibility become heir to him.

Guillotine

siderable effect. They recognize one God, Ormuzd, invisible and omnipotent, the creator, governor, and preserver of all things. He sprang from primeval light, which emanated from a supreme incomprehensible essence, called Zernane Akerene, or the Eternal. Ormusd created a number of good spirits to act as the medium of his bounty to men, and intrusted them each with the guardianship of a particular person or object, animate or inanimate. The sun is the eye of Ormuzd, and, like all the heavenly bodies, is animated with a soul. The spirits of the stars have a beneficent in-fluence upon the affairs of men, and can reveal the future to those who understand their signs; hence astrology has always been a favourite subject of study with them. The worship of idols is prohibited, but a reverence for fire and the sun inculcated, as emblems of deity. To Ormuzd is opposed Ahriman, the author of evil. The sacred fire which Zoroaster brought from of evil. The sacred fire which Zoroaster brought from heaven is kept continually burning in holy places, and is fed with choice wood and spices. Their funeral ceremonies are very peculiar. Fasting and celibacy are considered as displeasing to the deity, and polygamy is strictly forbidden. Their priests pass their time in praying, chanting hymns, tending the fires on the altars, burning incense, and performing certain ceremonies. Prayer, obedience, industry, honesty, hospitality, and aims, are enjoined, while anger, revenge, envy, hatred, and quarrelling, are strictly forbidden. The precepts of this religion are contained in the Zend Avesta, or collection of sacred writings which Zoroaster received from heaven. The original was lost at aster received from heaven. The original was lost at the time of the invasion, but copies of it were preserved.

GUELDER ROSE. (See VIDURNUM.)
GUELPHIC ORDER. (See KNIGHTHOOD, ORDER

OF.)
GUELPES AND GHIDELLINES, gwelfs gib'-bel-lines, the names of two political parties that for several centuries during the middle ages continued to agitate the distance of the middle ages and Italy. The factions arose turies during the middle ages continued to agitate the countries of Germany and Italy. The factions arose in the contest for the imperial throne between Conrad, duke of Franconia, and Henry the Lion, duke of Saxony, of the house of Guelph, or Welf. At the great battle of Weinsberg, in Suabia, in 1140, the adherents of Henry adopted the war-cry of, Welf, while those of Conrad took that of Waiblingen, a seat of the Hoberstate for family to which coursed belonged. The Hohenstaufen family, to which Conrad belonged. terms were continued to designate the two parties, the latter becoming corrupted into Ghibellines. The house of Holenstaufen having become the ruling power in Germany, the name of Guelphs was given to all who were disaffected towards it, while the Ghibellines were those who supported imperial authority.

As Italy became the chief theatre of the contests of As Italy became the chief theatre of the contests of these two parties, and as the Church was equally opposed with the Guelphs to the imperial power, it took part with the latter, and at length the popes became the leaders of that party. In the 13th century, under the reign of Frederic II., it came to be a contest between the temporal and spiritual power; and Italy was divided, as it were, into two camps, some cities ranging themselves on the Guelph side, while others remained attached to the Ghibellines. The former were generally the more powerful in the south of Italy, the latter in the north. After the German emperors lost their powering Italy, the names of Guelph and Ghibelline lost their foriginal signification, and were applied to various contending factions among the Italians themselves. In general, the Ghibellines were regarded as aristocratical in their ideas, while the Guelphs were considered as entertaining popular views; but sometimes we find the reverse of this to be the case, the Guelphs being allied with the governing party and the Ghibellines forming the really popular party. In 1334 Pope Benedict XII. forbade, under pain of the censures of the Church, the use of these once potent names; and in the following century they were generally the more powerful in the south of Italy, pain of the censures of the Church, the use of these once potent names; and in the following century they had become a mere traditional shadow.—Ref. Sismondi's History of the Italian Republic; Raumer's Geschichte der Hohenstaufen.

GURBILLA, gwer-ril-lä (Sp., a little warfare, from march, war), is a name applied in Spain to armed freasants or others who keep up an indepentant of hostile attacks upon an enemy. This harassing an enemy is particularly effective 992

in a mountainous or close country, and was adopted towards the French armies in the north of Spain during the peninsular war. The bands which conducted this desultory warfare were called partidas. In the recent civil wars which have distracted that

In the recent civil wars which have distracted that country, the guerrillas have borne a prominent part. Guerraeda, gat'-tar-dā (after Dr. Guertard, a French botanist), in Bot., a gen. of the nat. ord. Cinchonacea, a native of the West Indies, is the tree from which the beautiful zebra-wood of the cabinet-

makers is obtained.

GUILD, gild (Sax. guildan, to pay), is a society or body of individuals associated together for carrying on commerce, or some particular trade or business. Each member contributes towards the expenses; and hence the name. There existed at Rome various fraternities of tradesmen, which bore a considerable resemblance to our modern guilds, and were permitted to regulate their affairs by their own laws; but it is usual to trace the origin of guilds to the middle ages. Mechanical industry would never have flourished under the feudal system, had it not been for the unions formed among the workmen and merchants themselves. When the advantages of these associations became known and felt, they rapidly increased, and in the struggles between felt, they rapidly increased, and in the struggles between the citizens and nobility, the principal resistance against the latter was made by the guilds or corporations. As soon as the citizens acquired an influence in the ad-ministration, the guilds became the basis of the muni-cipal constitutions, and every one who wished to par-ticipate in the municipal government was obliged to become member of a guild. Hence we so often find distinguished individuals belonging to a class of me-chanics, of whose occupation they probably did not distinguished individuals belonging to a class of mechanics, of whose occupation they probably did not know anything. Guilds introduced the democratic element into society, and in their progress became the bulwarks of the citizen's liberty, and the depositaries of much political power. By the close of the 12th century, merchants' guilds were general throughout the citize of Europe. The drapers' company of Hamburg dates from 1153, and that of the shoemakers of Magdeburg from 1157. With the increase of their wealth and strength, the guilds either purchased or extorted deburg from 157. With the increase of their weath and strength, the guids either purchased or extorted from their rulers privileges, which, once obtained, they were careful never to give up. By the 13th century, they had acquired considerable power, and in the two succeeding ages they counterbalanced the power of succeeding ages tasy control danced the power of fine nobles. By degrees, they themselves grew into intolerable aristocracies, especially in Germany, where their exactions had to be curbed by the laws of the empire. Guilds were abolished in Prussia in 1810; but the want of such associations having since been felt, laws were enacted in 1840 to favour their re-establishment. In France, they were suppressed in 1776, but soon re-established, and not finally abolished till 1791. In England and Scotland, the exclusive privileges of the guildry companies have now been abolished.

the guilary companies have how been aboushed.
Guildhall, gild-hawl, is an important public building of the city of London, the seat of the municipal government, and the place of its civic meetings. Various courts are held here; and here, every 9th of November, the new lord mayor for the coming year cives a grand public dinner, at which her meisetr's November, the new lord mayor for the coming year gives a grand public dinner, at which her majesty's ministers and the great law officers of the crown are invariably present. This building was commenced in 1411, by contributions of several companies called guilds, aided by liberal donations from many private individuals. Of the original Guildhall little now remains but the stone and mortar of the walls, it having suffered greatly by the great fire of 1666. It was patched up by Wren, and again in the last century by

patched up by Wren, and again in the last century by Dance, who, in 1789, erected the present intensely barbarous front. The apartments contain some paintings and sculptures, but of very ordinary merit. The library contains a very large collection of early-printed plays and pageants, &c., connected with the city.

GUILLOTINE, gill-lo-leen, is the name of an instrument used for the indiction of capital punishment by decapitation. In general form it usually consists of two upright posts surmounted by a crossbeam, and grooved so as to allow an oblique-edged knife with a heavily-weighted back to descend surely and swiftly, when the cord by which it is suspended is let go. The instrument took its name from Joseph Ignace Guillotin, a physician in Parf, who was a member of

the French National Assembly at the time of the Revolution, and proposed its adoption by the Assembly. This name, however, was bestowed upon it in derision and santiapation, and clung to it, in spite of an attempt to call it the Louison, after M. Louis, the secretary of the College of Surgeons, who actually presided over the construction of the machine, which Guillotin had only indicated. Its adoption was proclaimed in a decree of March 20, 1792. Dr. Guillotin sank into ridicule and contempt, and after being imprisoned during the Jacobin reign of terror, was released at the gaodelivery on the 9th Thermidor, and died in his bed, in delivery on the 9th Thermidor, and died in his bed, in Paris, at the age of 76. It is a common error to sup-pose that he fell a victim to his own invention. To attribute the invention of the guillotine to Dr. Guillotin is also a mistake. It had been in use for centuries in Germany, in England, Scotland, and Italy. In Germany, the instrument was called der Planke der Diel, the plank of wood, and, in older language, Fallbeil, the falling hatchet. The English mode of decapitation had always been by the block and axe, with one local expansion.—that of the Halling stiket, which was local exception,—that of the Holifux gibbet, which was a perfect guillotine. Its use at Halifax is traced as far back as the reign of Edward III. the last crimifar back as the reign of Edward III.: the last criminals who suffered by it were executed in 1650. In the museum of the Antiquarian Society of Edinburgh, a rudely-shaped guillotine, called "the Maiden," is still preserved. The regent Morton was beheaded by this machine. Pennessik, in his "Description of Tweeddale," in speaking of the regent, says, "This mighty earl, for the pleasure of the place and the salubrity of the air, designed here a noble recess, and retirement from worldly business, but was prevented by his unfortunate and inexorable death three years after, A.D. 1581, being accused, condenned, and executed by the Maiden at the Cross of Edinburgh, as art and part of Maiden at the Cross of Edinburgh, as art and part of the murder of King Henry, earl of Darnley, father to King James VI., which fatal instrument, at least the pattern thereof, the cruel regent had brought from abroad to behead the laird of Pennecuick of that ilk, who, notwithstanding, died in his bed, and the unfor-tunate earl was the first himself that handselled that tunate earl was the first himself that handselied that merciless Maiden, who proved so soon after his own executioner." A machine was also used by the Italians which closely resembled the guildotine. It was called Mannia; and an engraving of it, as used in Italy, is to be seen in the Questiones Symbolicae of Achilles Bocchius, printed at Bologna in 1555. The eighteenth symbol in this work represents a Spartan about to deep by a kind of guillotine. In Louis Cranach's woodcuts of the "Marryrdom of the Anostles." urited in 1539. symbol in this work represents a Spartan about to die-by a kind of guillotine. In Louis Cranach's woodcuts of the "Martyrdom of the Apostles," printed in 1539, there is a representation of the death of St. Matthew by the guillotine, with a legend to this effect, "It is said that his head was chopped off by a falling-axe (fallbeil), after the manner of the Romans." The guillotine was not, therefore, a new instrument when it was adopted by the French. After being in exer-cise for a few months it became the delight of the cise for a few months, it became the delight of the Parisian mob; and not of the mob only, for it was canonized in the philosophical rubric as la Sainte Guillotine, and, in miniature, became the model of ornaments for women and toys for children. During the period

the name is still used to designate a sum of twenty-one shillings; and it is outlomary to recken professional fees, voluntary subscriptions, &c., in guiness, which is supposed to raise them above mere pounds shillings

and pence transactions.

GUINEA CORN. (See HOLOUS.)

GUINEA-FOWL. (See FOWL.)

GUINEA-FIG, Caria codaya, is an animal of the gen.

Rodentia, a native of South America, but which is now quite domesticated in Europe. From the beauty of its appearance, this gnimal seems to have attracted the attention of Europeans. It is one of the species called agouts, which are well known in South America and the West-India islands. Its ears are large and broad; the upper lip is divided in two, and the hair or fur is erect, and somewhat resembling that of a pig (whence erect, and somewhat resembning unation a programmits name). The colour of the guinea-pig agenerally white, with black spots, although this is somewhat variegated by orange shotches on the coat. It has divors not be fore legs and three on the bind ones, and is utterly destitute of any caudal appendage. In the short of the colour of the c is utterly desitate of any caucal appendice. In any about 50 miles apps are extremely neat, as they are of standy seen smoothing and arranging the hair work forms the outer regiment of their cost. Their work voice is a grunt or feeble squeal, which remarks even more analogous to the pig, to which they are aften likeand. The guines mig, is its wild state. often likened. The guines pig, in its wild state, inhabits dry sandy places, and its flesh is esteemed a great dainty by the natives of South America.

great dainty by the natives of South America.

GUITAR, gii-tar' (Fr. guitars', a musical stringed instrument, supposed to have originated in Spain, where it is very common; indeed, so much so, that there are few, even of the poorer classes, who cannot play on it, while geattlemen employ it to seronade their mistresses. About the middle of the last century it instresses. About the mindio of the last century it became so popular in England as to greatly injure the sale of other instruments. The demand for it is said to have been greatly lessened by Mr. Kirkman, a manufacturer of harpsichords, who having bought a number of cheap guitars, distributed them to balladsingers, at the same time teaching them to play a few singers, at the same time teaching them to play a few easy times, thus rendering it so common that fashionable people threw it by in disgust. The guitar is of a somewhat oval form, having a neck similar to that of the violin. The strings—six in number—are stretched from the bead to the lower end, spassing over the sounding-hole and bridge. The three first, E, B, and G, are, like the gut strings of the violin, called the strelle; and the other three, which are of gut or silk. treble; and the other three, which are of gut or silk, and wound with silver wire, constitute the bass. All the strings are tuned by fourths, except the third, which is tuned one third below the second,

Gules, gules (Fr. yurules), in Her., the term used to denote a red colour in armorial bearings. In engrav-ings of coats-of-arms this colour is expressed by parallel lines crossing the field or charge in a perpendicular

GULF STREAM. (See OCRAN CURRENTS.)

GUID-WEED. (See SARGASSUM.) GUIL, gult (Welsh guylon), is a Linnean species of aquatic birds, belonging to the longinenuse division of Palmipedex in Curier's system. The birds of this webfor women and toys for children. During the period for well-known marine genus are dispersed over every part of the globe, and in some places, at certain seasons of the year, are met with in multitudinous quantities. Their characteristics are as follows:—A strong straight bill; the body classed with a great quantity of down and haked above the knees, and the feet are webbed. The guils, which are seen on the different coasts, mostly assemble in flocks, and are characteristic by the red great red with a great quantity of down and naked above the knees, and the feet are webbed. The guils, which are seen on the different coasts, mostly assemble in flocks, and are characteristic by the red great red with a great quantity of down and naked above the knees, and the different coasts, mostly assemble in flocks, and are characteristics. Their characteristics of the guils

shoals which frequent the waters round our coasts. The gull is avery courageous bird, and there are many anecdotes related of the encounters witnessed between it and some large fish, which it has selected for a prey, it and some large fish, which it has selected for a prey, but which proves too strong for its assailant. The black-backed gull, the ivory gull, and the horny gull have but little distinction from the common gull. The skua gull is about the size of a raven; the back and head, and upper parts of the body, are of a deep brown colour, the under parts pale ashy grey; the legs black, and the talons very strong and hooked. It is a native of the North, although occasionally found in England. It is a very formidable bird, partaking of the fierceness of the eagle, and not only feeds on fish, but it also preys on lambs and other small animals. In the Shetland isles, and in other northern rock-bound coasts, it is seen often. The arctic gull is very similar to the common often. The arctic gull is very similar to the common gull, and needs no special description. It is found in guil, and needs no special description. It is found in northern regions,—whence its name, and it is peculiar only from the fact of its parasitical propensities. It ever fishes for itself, like other water-lowl, but puranes smaller guils which have captured any booty, is smakes them drop it. It then descends with great praying, and catches its stolen prey before it can praying water.

GULEAT. (See (ESOPHAGUS.)
GULEAT. (See (ESOPHAGUS.)
GUM, gum (Sax. goma), in Anat., is that cellular and
elastic fleshy substance which covers the alveolar portions of the upper and lower jaw, and envelops the
neck of the teeth.

Gun, gam (Fr. gomme), a vegetable product, which forms a slimy solution with water, but is insoluble in alcohol, ether, and oils. There are six varieties of alcohol, ether, and oils. There are six varieties of gum,—gum arabic, gum Benegal, gum of the oherry and other stone-fruit trees, gum tragacanth, gum of Bassora, and the gum of seeds and roots. All these gums, except the last, flow spontaneously from the branches and trunks of their trees, and sometimes from the fruits, in the form of a mucilage, which dries and hardens in the air; the gum of seeds and roots, however, requires to be extracted by boiling water. A number of very different substances are confounded in commoree under the name of gum. Thus, gum elemind gum consl. which are true resins: gum acomoniaand gum copal, which are true resus; gum ammonia-cum, which is a gum-resin; and gum elastic (caout-chouc), which differs from both, are all called gums. Gum arable is obtained from the Acacia arabica; or and hollow on the other. It may be bleached by exposure to the atmosphere and sunlight at a temperature of 212°. Its specific gravity is 1°35°. It is used in medicine, and also in order to give lustre to crapes and other silk fabrics. Gum Senegal is collected from the Acacia Senegal by the negroes during the month of November. Its specific gravity is 1°436, and its chemical properties and uses are similar to those of gum arabic. It is largely used in calco-printing. Gum tragacanth is gathered in Crete and the neighbouring islands. From the Academ Tragacanth about the tragacanth is gathered in Crete and the neighbouring islands, from the Astragalus Tragacantha, about the end of June. It is white or reddish in colour, almost opaque, and has the appearance of twisted ribands. It is difficult to pulverize it without heating the mortar. When plunged into water, it partially dissolves, swells, and forms a very thick mucilage. (Junt 1792, 1892) swells, and forms a very tinck mucliage. Clim tragacanth has a speake gravity of 1'384, and is used in calico-printing and by shoemakers. (For other gums, see Bassora Gum, Britter Gum, Drithin). Most of the substances called gums are resins or gum-resins. Gum-both, in Surg., is a small abscess, which forms in the cellular substance of the gum. At first it is sufficiently until the protect it against cold, but if it.

in the cel'llar substance of the gum. At first it is sufficient, the only to protect it against cold; but if it party and the dynamot, the process of ripening may be party. In 133 t applications to the cheek, next to the pain of the the pain be excessive, a leech applied to none pote will usually afford relief. As soon as the had be so of matter can be ascertained, it should be let mon, a free incision.

Of the interior plants, obtained by sportaneous exceptions of sesin and gum, the proportions varying in the different varieties, and with these are commonly associated essential oil and other vegetable substances,—
984

as starch, bassorin, extractive, &c. They are most of them hard and dry substances, brittle and opaque, rarely translucent like the resins. Some that are rarely translucent like the results. Some that are semi-liquid and viscid, as the sagapenum and galbanum, become hard in very cold weather, and may then be pulverized. At a moderate heat these are sufficiently fluid to be strained through a cloth; and all the gum-resins may be thus strained and purified by first boiling them in water. They are partially soluble in water or in alcohol, and wholly so in a mixture of these. Polaran are all distantibled force provinces. these. Balsams are distinguished from gum-resins by containing benzoic acid. The most important of the gum-resins are aloes, ammoniac, asafœtida, bdellium, euphorbium, galbanum, gamboge, myrrh, olibanum, sagapenum, sad scammony, all of them being of great service in commerce and industry.

GUM-TREES. (See EUCALNITUS.)

GUN, gun (Ang. Sax.), an instrument consisting of a barrel or tube, of iron or other metal, from which balls, shot, or other missiles are discharged by the explosive force of gunpowder. The larger species of guns are called cannon; the smaller species are called fifles, muskets, carbines, fowling pieces, &c. The manufacture and construction of cannon have been fully described in the articles on ARTILLERY and CANNON, to which the reader is referred. A description of the latest improvements in the manufacture of small fire-arms will also be found under the head RIFLE. The ordinary muster or fowling-piece consists of two distinct parts,—the metallic and the wooden part. The first comprises the barrel, the lock, and the mounting, together with the bayonet and ramped for military arms; the second comprises the stock, and, in fowling-pieces, the ramrod also. The interior of the barrel is called the hore, its diameter the calibre, the front end the muzzle, and the back end the breech. front end the muzzle, and the back end the breech. The proving of gun-barrels is indispensably necessary to insure confidence in their safety. Next in importance to the barrel comes the gun-lock. Formerly all guns were made with fint locks, working with a spring; but at the present day percussion or detonating locks only are used. Among the most important technical terms employed by sportsmen to distinguish the different parts of a gun are the following:—The butt of stock, the shouldered extremity of the stock; the chain or swivel, a small catch suspended from the neck of the tumbler, to receive the extremity of the mainspring; Acacia arabia is obtained from the Acacia arabica, or tumber, to receive the extremity of the mainspring; Acacia arabica, acacia arabica, acatia cavity within the breech, to reand in Arabia. The commercial gum of this kind con-feeive the powder; the cock in the flint gun holds the sists of a number of small pieces rounded on one side flint in its jaws, and in the percussion gun is often and hollow on the other. It may be bleached by expocalled the striker; the guard, the bow which protects sure to the atmosphere and sunlight at a temperature the trigger; the heel-plate, the plate with which the of 212°. Its specific gravity is 1°355. It is used in meprincipal works of the lock; the mainspring works the tumbler with the cock; the scear, that which catches the tumbler for half or whole cock, on being pushed up by the trigger; the tumbler, the movable centrepiece of a lock, which falls into, and is subservient to, the cock; the worm is the screw at the end of the

io, the cock; the worm is the screw at the end of the ramrod.

GUN, AIR. (See AIR-GUN.)

GUN, AIR. (See AIR-GUN.)

GUNGAT, a term formerly applied to a small vessel mounting only a single gun, and used for coast defence; but now the word gunboat is synonymous of a totally new class of vessel. The experience of the last Russian war showed us that vessels of light draught of water, which could be rapidly propelled through the sea, and which could carry one or two guns of large calibre, would be far more useful sometimes than line-of-battle ships; accordingly, our fleet of gunboats was constructed on entirely new principles. They are generally armed with one 68 or 100-pounder Armstrong gun, which can be used either ahead or astern, according as required. Some have in addition to this, a 32-pounder, or brass howiteers. They are propelled by engines of from 20 to 80 horse-power. In the new gunboats constructed the crew are sheltered by shifting iron screens, and the vessels themselves are plated externally with armour-plates. Their rig is restricted to a very light form, and consists of three masts, very short in length, and fitted only with gaff-sails.—Ref. The Screw Fleet of the Navy, by Captain Halsted, R.N.; Eng. Cyclopædia—Arts and Sciences, and the Cyclopædia Britannica.

GUN-COTTON. (See Pyroxxiline.)

GUN-COTTON. (See PYROXYLINE.)

### Gun-Metal

GUN-METAL, in Metall, an alloy containing 90 5 per cent. of copped and 9 5 of tin, used for casting pieces of ordnance and those parts of machinery which are subjected to considerable friction.

GUNNER, gun'-ner, in Mil., a name applied to soldiers belonging to the royal artillery, in contradistinction to those who are called drivers. Some artillerymen rank as master gunners, and there are others attached to the corps and considered as forming a portion of it, termed invalid gunners. In the royal namy the gunner holds the highest rank among warrant officers. Gunners in the navy are divided into three classes, with pay varying from £10 to £7 per month when at sea, and from £8, 10s, to £5, 10s, per month when in harbour. The gunner must be a man of when in narrour. The gunner must be a man of tolerably good education, and has to pass a severe examination before he is considered as qualified to enter on the duties of his post. Whenever a gunner returns from service abroad, he has to go on board the Excellent gunnery ship at Portsmouth, to make himself accounted. himself acquainted with the latest improvements in the science. On board ship the gunner and his mates have to instruct the midshipmen and ship's crew in the great-gun, small-arms, bayonet, and cutlass ex-ercise; and the chief gunner has the charge of the magazine, and serves out the ammunition and military stores, keeping a strict account of the expenditure. He must necessarily have a knowledge of geometry, and also be acquainted with the duties of practical seamanship. He has to superintend the fitting out of boats for active service. Gunners hold rank next to second masters. Although holding a position of such importance, the gunner is one of the worst paid officers in the British service. When he is no longer fit for service, he is allowed to retire on a small pension, averaging about 445 a year, and if he die on active service, his widow is also entitled to a pension of small amount.

GUNNERA, gun'-ner-d (after Ernest Gunner, a Norwegian botanist), in Bot, a gen, of the nat. ord. Arabacev. The species G. scabra, a native of Chili, is remarkable for its enormous leaves, which are sometimes eight feet across. Its fleshy leaf-stalks, which resemble those of the rhubarhs in appearance, are eaten. Its roots are astringent.

Gunner, gun'ner-e, the science which treats of the theory of the flight and motion of projectiles discharged from cannon and small-arms, and teaches the method of employing these weapons in the most effectual manners for the purposes of attack and defence. The earliest treatise on the path described by a projectile during its flight, seems to be one written by a mathematician mamed Sartalea, about the middle of the 16th contury. Galileo demonstrated that a shot fired from a gun would trace a parabolic curve in its passage through the air, if the resistance of the air had no influence, as it has, in materially altering the form of the path it describes. It will be readily understood, that if the resistance of the air and the attraction of gravitation could be removed, or, in other words, if a shot could be fired in vacuo, it would go on for ever in a line corresponding to that of the axis of the piece, produced indefinitely, with the same initial velocity, or the velocity which it possessed when it left the cannon's mouth. But supposing the effect produced by the influence of the air to be neglected, and gravity alone to act on the ball, it is found that the action of gravitation constantly acting on the projectile at every point of its flight, in a line which may be densidered as perpendicular to the horizon, tends to draw it out of the straight line, which it would have described if the force of gravity did not exist, and eventually brings it to the ground, after describing a parabolic curve. It was generally considered by mathematicians, from the time of Galileo, that the path of a projectile was that of a parabola, and that the resistance of the air had but little, if any influence, in altering its form; but it was reserved for Newton to show that its true path, under the combined influence of the resistance of the air and the attraction of gravitation, was that of an hyperbola while passing through a medium offering a uniform resistance. He also showed that the resistance of the bair had but little, if any

### Gunnery

ters and the density of the medium through which ters and the density of the medium through which they pass. To determine and calculate the time of flight, the horizontal range, and the greatest height to which a shot will rise during its light, requires a knowledge of trigonometry. It may, however, be said, that the range and time of flight depend entirely on the charge and the elevation of the gim. The greater the charge, the greater will be the range and the velocity invented to the above the coercity notice and the imparted to the shot up to a certain point; and the same holds good with regard to elevation, provided that the same charge be used in firing each shot, at the different elevations. A knowledge of the time in which a projectile will describe its flight is most necessary, a projectile will describe its flight is most necessary, especially in firing shells, that the gunner may know how to regulate the length of the fuse, to insure the bursting of the shell at the time of reaching the object at which it is discharged. This is taught by the study of gunnery, which also makes the military engineer acquainted with the effect produced by shot engineer acquainted with the effect produced by shot engineer acquainted with the effect produced by shot when discharged in masses, and for a long time against wood, stone, and other materials, under various circumstances; and gives him data for the construction of walls bomb-proof roofs, and vessels of sufficient strength to offer effect at resistance to the weight of the projectiles that may be directed against them. effect of the resistance of the atmosphere to the motion of a projectile is one of the most important sections of the science of gunnery. It has engaged the attention of some of the most eminent philosophers, both in ancient and modern times, on account principally of the great difficulty of determining, by experiment, the correctness of any particular hypothesis. Much difference of opinion is entertained as to the absolute effect of this retailing function of the product of the prod of this retarding force (which is, in fact, the science of sero-dynamics) upon bodies moving in the atmosphere with great velocities; and although sufficient is known to guide the practical gunner, still, as a scientific question, it is one of considerable interest, from the fact of tion, it is one to considerable interest, from the base of its practical importance. Dr. Hutton, in his "Mathematical Tracts," draws the best hypothesis on the subject; and although some of his results have been disproved by experimentalists who have inquired into the theory, and tested its results, since the time of Dr. Hutton, yet his deductions being generally found correct, are by far the most trustworthy to follow by any one who wishes thoroughly to investigate the science of aero-dynamics. The resistance which a body meets with in its motion hrough the air will first depend upon its velocity, and the form and magnitude of the surface opposed to the the form and magnitude of the surface opposed to the fluid; secondly, upon the density and tonacity of the fluid; or cohesion of its particles, and also upon the friction which will be caused by the roughness of the surface of the body; and, thirdly, upon the degrees of compression to which this fluid, supposing it to be perfectly elastic, is subjected, as on this depends the rapidity with which it will close in and fill the space behind the body in motion. With regard to the velocity of the body, it is evident that a plane moving through a fluid in a direction perpendicular to its surface must impart to the particles of the fluid with which it comes in contact a velocity equal to its own; and from this cause alone the resistances should be in the proportion of the velocities; but the number of particles struck by the moving body in a certain time being also as the velocity, it follows from these two causes combined, that the resistangem a fluid to a body in motion, which arises from the inertia of the particles of the fluid, will be in the due proportion the square of the velocity imparted to the mo the square of the velocity imparted to the mo body. Secondly, a body moving in a fluid must come the force of the cohesion of those parts w come the force of the cohesion of those par-separated, and the friction; both of which totally independent of the velocity. The ance, therefore, from cohesion, friction will be partly constant and partly as the velocity. Besides, the number of pa-the number that are separated will of the medis;—from which we dry mula :- Let d represent the der mula:—Let d represent the velocity of the moving body, a inertia, and b the coefficient then ado\* + bd will be resistance. The resistance squares of the velocity

**9**85

squares of the velocities multiplied by the densities in different fluids. Thirdly, if the body can be moved so rapidly that the fluid cannot instantly rush in behind rapidly that the fluid cannot instantly rash in behind it, as is found to be the case in the atmosphere, the resisting power of the medium must be considerably increased; for the projectile being deprived of the pressure of the fluid on its hind part, must support on its fore part the whole weight of a column of the fluid, over and above the force employed in moving the portion of the fluid in contact with it, which force is the sole source of resistance in the discontinued fluid. Also, it must be added, that the condensation of the air in front of the body will influence considerably the relation between the resistances and the velocities of relation between the resistances and the velocities of an oblique surface; and it is probable that, although an oblique surface; and it is probable that, although the resistances to a globe may, for slow motions, be nearly proportional to the squares of the velocities, they will, for great velocities, increase in a much higher ratio. The recoil of a gun must necessarily diminish the velocity of its projectile; and this has been exercilly borne in mind by men who have made ganney their especial study, as Sir William Armatrong and Mr. Whitworth. It must be also remembered, that the increased extent of range and the greater certainly of hitting the object against which the firing is directed, is due to the method of rifling or grooving the interior of the bore of the piece, which imparts the interior of the bore of the piece, which imparts rotation to the missile after it has left the muzzle of the gan. The use of elongated shot and shell also contributes greatly to this result, as they do not present a greater amount of surface to be acted on by the air than apherical shot; but, in consequence of their air than spherical shot; but, in consequence of their greater weight, they possess a far greater power of maintaining their initial velocity. It is difficult to treat on such a subject in a satisfactory manner without entering fully into details; and this renders it manifestly impracticable to do more in the present instance than to give the briefest sketch of the objects and nature of the science of gunnery, the theory of which belongs entirely to the higher branches of mathematics.—Ref. Robins's New Principles of Gunnery; Hutton's Mathematical Tracts; Sir Howard Douglas's Treatise on Naval Gunnery; Boxer's Treatise on Artillery. tive on Artillery.

GUNFOWDER, gun'-pow-der, a mixture of nitre, char-coal, and sulphur, in proportions which very slightly in coal, and sulphur, in proportions which very slightly in different sountries, and according to the uses to which it is applied. Its action is dependent on the rapid oxidation of the charcoal by the nitre, and the suddery evolution thereby of heated gas. The powder which appears to have the greatest propolling force is that which contains an equivalent of nitre and sulphur united to three of carbon. Many other chemical detonating compounds have been proposed, but none of them are equal to gunpowder as at present manufactured; the principal objections to their use being the comparative dancer attendant on their manufacthe comparative danger attendant on their manufac-ture and transport, and the too sudden evolution of gas at the time of their ignition. The following table contains the composition of most of the varieties of

gunpowder :-

be dried in any one stove or place at any one time (altered by 23 & 24 Vict. c. 130, to 50 bs. and 50 owt. respectively; which aut also declares the quantity to be pressed at one time not to exceed 10 owt., or the quantity to be corned 12 cwt. In terms of this sot there must be a store maguzine of brick or stones at least 140 yards distant from any house used in making powder. No dealer is allowed to keep more than 200 powder. No dealer is allowed to keep more than 200 lbs., nor any person not a dealer more than 50 lbs., except in licensed mills, or to the amount of 300 lbs. for the use of collieries, and within 200 yards of them. By 23 & 24 Vict. c. 130, not more than 30 barrels are to be carried at once by land carriage, except in an in-closed wooden van, which may contain 40, or if it form part of a railway train, it may contain 100. Not more than 500 barrels at once to be conveyed by water, except in vessels importing or exporting, or going coastwise. All gunpowder must be contained in wooden boxes or in All gunpowder must be contained in wooden boxes or in barrels, without any iron about them, and well secured, each box containing not more than 100 lbs. Carriages must be completely covered over, and vessels used must have a close deck. To smoke, have fires, lighted candles, or lucifer matches, on such vessel, while the hatches are open, involves a penalty of £5. The exportation of gunpowder may be prohibited at any time by proclamation, or by an order in council. Stringent regulations are enacted by the last-mentioned act regarding the making of percussion-caps, ammunition, freworks, fulminating mercury, and other explosive fireworks, fulminating mercury, and other explosive compounds. Manufacturers must take out licenses, and not make percussion-caps or fireworks within 50, and not make percussion-caps or interorise within 50, or ammunition, full-ministing mercury, or other such article, within 100 yards of any dwelling-house or other manufactory. Not more than 50 lbs. of gampowder or 30 lbs. of explosive compound to be in the respective buildings at one time. To sell fireworks without a license are a parameters and a single property and a sinclusive and a single property and a single property and a single

Dillicense, or to a person apparently under sixteen years of age, involves a penalty of £5.

GUNFOWDER PLOT, the name of a conspiracy formed in the second year of the reign of James I. (1604), for the purpose of destroying the king and the parliament at a blow. The Roman Catholics having been disappointed in the grantities of individual to the grantities. pointed in the expectations of indulgence from King James, Catesby and Percy, two Catholic gentlemen of ancient family, with a few others of the same persussion, determined to run a mine below the hall in which parliament assembled, and on the first day of the session, when the king and royal family would be present, involve the whole in cae common ruin. A house close to the old palsec of Westminster was hired by Catesby, and mining creations commenced; but they were obliged to be abandoned. A rault below the House of Lords, which had been used to store coals, heing to let, Catesby hired it March 25, 1605, as being admirably suited for their purpose, and two hogsheads and by studed for their purpose, and two nogeneous and 38 barrels of gunpowder were lodged in it, the whole being covered with sticks and faggots, and the doors thrown open, so as to prevent suspicion. Everything was at length prepared for the set the control of the plot, which was arranged for the 5th November, the day on which was been as the control of the control was arranged for the 5th November, the day on which parliament was to be reopened. An anonymous letter was sent by one of the conspirators to Lord Konteagle on the 26th October, advising him not to attend the opening of parliament; "for God sad man hath concurred to punish the wickedness of this time." This be communicated to the secretary of state, Lord Salisbury, who, although apprehending nothing, thought proper to lay it before the king. James saw the matter in a more serious light, "and judging that the threatened dancer was from gunpowder, ordered the matter in a more serious nignt, wat junging these are threatened danger was from gunpowder, ordered the cellars beneath the parliament house to be searched. There is good reason for believing, however, that Montesgle and James were cognizant of what was going on before this time, and that the letter and this account of the matter was not in fur the automate. going on before this time, and that the letter and this account of the matter were got up for the purpose of concealing the treachery of some of those concerned. The vault was searched on the evening of the 4th November, and Guy Fawkies, an officer in the Spanish service, who was to fire the mine, was found at the door, with a dark lantern, and matches is his pocket The other conspirators fied to Holbeach House, is Worcestershire, where they were attached on the Ste

#### Gunshot Wounds

en the 5th of November, in commemoration of the deliverence of the nation from the perils of the Gunpowder Plot.

SURBOY WOUNDS, gun-shot woonds, is a term em-ployed in Mil. Surg. to denote wounds produced by earnon-balls, sullets, &c., striking against the body. They differ in many respects from ordinary wounds, and constitute a distinct branch of science of themsnd constitute a distinct branch of science of mem-selves. Frequently, on a person being struck, he is not-conscious of any pain, and he is first made aware of his wound by insbility to use the park, or by feeling the shoot trickling down. Generally, if the wound be at all severe, the patient becomes deadly pale, frem-bles and saying about to die, but would with the sid bles, and seems about to die; but usually, with the aid of stimulants, these appearances pass off in a few hours. If they continue unabated, they give reason to fear the worst. It was long a generally received spinion that a person might be injured by the "wind of a shot," without being struck by it at all; but this idea is now exploded, for persons have had portions of their clothes carried off by large shot, and even their sars or noses shot off without at all suffering from the wind of the shot. The real cause of such injuries wind of the shot. The real cause of such mignries is a ball whose force has perhaps been somewhat spent by previous obstacles, striking the part obliquely, and then glancing off, not breaking the elastic skin, but breaking or bruising the parts underneath. When a ball enters the body, the wound appears somewhat smaller than the ball itself; its edges appears somewhat smaller than the ball itself; its edges are ragged and invested, and the part around has a bluish or black colour from the bruise. When it passes irrough the part, the specture by which it makes its exit presents quite a different appearance. It seems somewhat larger than the ball, the edges are everted, and there is little-discoloration about the wound. Frequently a ball, if it enter obliquely, or be nearly ipent, instead of pursuing a straight course, becomes leflected, and may be found lodged in, or may pass out it a part at a considerable distance from that at which t entered. One is said to have passed completely ound the neck, and to have been found close to the sperture by which it had entered. Excessive bleeding s not so common after gunshot wounds as after other rinds; but it sometimes occurs, and may be fatal if not ittended to. Where it can be done, the finger should se inserted into the wound, and pressed upon the vesiel, otherwise a handkerchief should be tied very tightly Lthe limb above the wound. It is well to examine

and as early as possible, in order to ascertain mount of injury; at least, so far as this can be without aggravating the case. The ball or other gn substance ought to be removed, if that can be effected; but otherwise they ought, in the mean be let alone. As the walls of the wound slough arate, the opening will become larger, and hen fall cut, or be easily removed. Some-remain embedded in the tissues, without much or any inconvenience. If, after the id suppuration, the ball accounts fixed, and atton continues to be excited, and abscesses ts track, then it may be necessary to find and use every means to remove it. The sings should only at first be applied to the piece of linen, spread with some mild ointtipo of their, system with some mind one tipo of a fag. kept. constantly moist with cold Aprilent medicine should also be given, and a times it is advisable to bleed the patient. After a

wdays, when suppuration has set in, the treatment hould be changed, and in place of the cold application, both os that get, and in place of the cold application, one warm emolitent poultice, or list dipped in warm ster, should be adopted, and the system strengthened mild tonics and a nutritious diet. The inflammation nich precedes suppuration is usually very intented normanied with great swelling, heat, and pain of sompanied with great sweaking, near, and pain of surrounding parts, and severe constitutional disbance, fever, sleeplosaness, &c. These symptoms are when suppuration is fairly established, the surading inflammation is lessened, the fever subsides, in slight cases the health may seem but little ted. In severe cases, however, hectic fever superand the best of the series of

### Guttifere

may have been injured by the ball. In such a case, the vessels must be out down upon, and fied both above and below the opening. In cases where the parts beneath are greatly bruised, but the skin itself is not broken, it is recommended to make one of two invisions, in order to clear out some of the coagulated blood, and to permit the discharge of the slough, Where the injury is very considerable, it is sometime necessary to have recourse to amputation. When it may be necessary to adopt this course will depend upon necessary to adopt this course will depend upon the circumstances of each particular case; no gene-ral rule can be laid down regarding it. In military practice, however, it is often necessary to simputate in cases where, in civil practice, it would be scarcely justifiable, from the danger in healing being less, its not requiring so much attention, &c. The best time justifiable, from the danger in healing being less, its not requiring so much attention, &c. The best time for amputating is immediately after the patient has recovered from the depressing affects which usually follow the reception of the wound.—Ref. Hunter on Gunshot Wounds; Guthrie on Gunshot Wounds of the Extremities; Larrey's Mémoires de Oktrurgie Militaire; English Cyclopadia—Arts and Sciences.

GUNTER'S CHAIN, gun'ters, a chain commonly used in the mensuration of land, and so named from its being. invented by Mr. Ganter, a celebrated mathematicism. The chain is 66 feet in length, and is divided into 190 links, of 7.92 inches each; from which arrangement, acre of land is equal to 10 square chains.

GUNWALE, or GUNNEL, guntuel, sing. Sar.), the upper edge of a ship's side; the uppermost wale of a ship, or that piece of timber which unites on either side from the quarter-deck to the forecastie.

side from the quarter-deck to the forecastic.

Gut Manufacturus: (See Cargur Strings.)

Gutta-percha, gut'-ta pert'-shd, the concrete juice of
the Isonandra Gutta, a tree belonging to the fam.

of the Supotacea. (See Isonandra.) It grows abundantly in Singapore, Borneo, and other islands of the
Eastern Archipelago. The tree which is called percha
grows to the diameter of five or six feet, and, on being
patched vialds a milky uite, which saddings after grows to the diameter of five or six rest, and, on being notched, yields a milky juice, which salidies after exposure to the air, forming the gutta-percha of commerce. It is a tough, inelastic substance, becoming soft and plastic at 212°, at which temperature it may be moulded into shape, which it retains without change until it is cool. Its plastic properties render it extremely useful in the arts, and it is much employed for anyting easts and impressions. Rearts ther it extremely useful in the arts, and it is much employed for copying easts and impressions. Beautiful mouldings, picture-trames, and a mumber of ornamental articles, are made from it. It also possess the valuable property of welding together at the see the valuable property of weating edge-ness a more temperature of bolling water. It is a powerful insulator, and is consequently much used for coating the wires for telegraphic purposes. Being impersious to moisture, and resisting the actions of acids and alkalies to a great extent, it is of much use to the chemist as a material for making bottles, carboys, baths, to. It was at one time much used for lathe-bands; but it has was at one time much used for lathe-bands; but it has been superseded in a great measure by those made of vulcanized rubber. It is insoluble in water, but dissolves in benzole, chlosoform, bisulphide of carbon, turpentine, and the essential oils in general. Payen states that the purified gutta-percha of commerce consists of 75 to 80 per cent. of chemically pure gutta-percha, which is insoluble in ether and alcohol, and a white and yellow resin, soluble in boiling sleohol. The crude lumps are imported in the forms of fab. animals. crude lumps are imported in the forms of fish, animals crude lumps are imported in the forms of fish, animals, and blocks, which are softened by boiling water, and passed through a series of kneading, thug, and cutting machines, by means of which are the stones and other solid matters are extracted. It is then sulmitted to the action of mastizators, and rolled fashioned into the desired shape. It may be into thin transparent sheets, which are much particularly important time. Dr. Cattell, of London, has succeed from guite persons of the property to the proper ture. Dr. Cattell, of London, as succeeding gutta-percha so perfectly from a matter, that it presents the appearance its purified condition it is useful for ent purposes.

GUTTA BEBENA. (See AMADEC GUTTIFERE, OF CLUSIAGE a drop; fera, I bear), in Bot gosteen fam., & nat. ord. of Thalamillora, consisting having the following

order are natives occur in Madagascar, it. There are 32 genera L. They are chiefly remark

of South America; Dut. few corner in Madagescar, and on the African continent. There are 32 genera, including about 18 access. They are chiefly remarkable for yielding a fellow gumi-resin of an acrid and purgative mature. In histy cases, however, the frills are edible, and are held in high estimation for their delicione flavour. (See Gancura, Manwar, Masta.) Gurrurals, guf-ta-viels [lat. gutter, the throat), is a mane given, in Grim, to certain sounds formed in the threat or back part of the mouth. In English there are, properly speaking, no gutterals; but the filastials, y and t, are nearly sliced to them. In the Spanish language alone, of those derived from the Latin, see gutterals common. In German, the gutters of the course in Scotch in such words as look. The Arabian language is full of antimals.

# Gymnastics

of a kind offensive to the government, they were of a kind offeneive to the government, they were abolished in 1886. The practice of gymastics was, however, kept up by the troops, and with such evident success that a similar course of training was adopted in the French army in 1844. England was late in recognizing the advantages of this kind of training; but the troops at Aldershot and other camps are now out the troops at Autorian and other temps are now regularly instructed in the science. Gymnasis have, however, been long in use in private life in this country. The gymnastic exercises adopted by the puglists and wregulers of the present day in their course of training are not able to produce on the mind or body any de-sirable effect; and the same was observed in the con-dition of the athletæ of old. But gymnastic exercises, dition of the stricts of old. But gymnastic exercises, practized under proper control, must act beneficially, both mentally and physically. As Montaigne observes, "It is a soul, not a body only, which we educate; it is a man, of whom we must not make two; we must not train the one without the other, but must guide and lead them like a pair of horses harnessed to one shaft." lead them like a pair of horses harnessed to one shaft."

Gymnastics act upon the courage, and produce independence and presence of mind. Besides being a suitable interruption to mental labour, and the best recreation after it, they produce cheerfulness, and restrict the fancy and imagination to reasonable limits. "If you wish to develop the mind of a pupil," says Rousseau, "develop the power which that mind has to govern; exercise his body make him healthy and strong, that you may make him prudent and reasonable." The gymnastic system of Ling, referred to in the article Education, is considered one of the to in the article EDUCATION, is considered one of the best methods of training now in use. Under the name of free exercises, in Ling's system, are included such exercises as are performed without the help of technical apparatus, such as ropes, ladders, dumb-bells, &c. The different species of free exercises consist, first, in movements of the limbs on the spot, and without reciprocal support; second, in movements from the spot, and without support; third, in movements with supand without support; third, in movements with sup-port; fourth, in wrestling exercises; and fifth, in the exercises belonging to asthetic symnastics. The free-dom of Ling's method from violent exertion, and the dom of Ling's method from violent exertion, and the physiological principles on which it is founded, render it superior to every other system. In general all methods of instruction are divided into a number of courses regularly graduated, beginning with elementary and particular movements, so as to render every part of the body pliant, and to develop the muscles. These exercises are called elementary gymnastics; while exercises in leaping, vaulting, climbing, swinging, walking on stilts, &c., are called applied gymnastics. In ordinary gymnasia, the principal apparatus employed consists of the horizontal pole, the parallel bars, the masts or poles, the ropes, the triangle and rapize, the ladder, the wooden horse, the inclined plane, and the flying-course, or giant's stride. The rapize, the ladder, the wooden horse, the inclined plane, and the flying-course, or giant's stride. The norizontal pole is used in order to develop the strength of the hands and arms, though many other exercises are performed on it. The parallel bars are mostly about 8 feet long, and fixed about 2 feet apart, at a height of 30r 4 feet from the ground. The exercises upon them, which are of great variety, tend to strengthen the arms and chest, and to render the body pliant. The masts and poles, which vary in their inclination, are used for climbing purposes. The triangle and tra-The masts and poles, which vary in their inclination, are add for climbing purposes. The triangle and trapes for modern gymnasia, as the lightness of their contruction, and their being constantly in motion, make the evolutions performed on them appear easy and graceful. The wooden ladder and the rope ladder graceful. The wooden ladder and the rope ladder are used generally to render the body supple. The wooden horse, which can be lowered or raised on its stand when required, is for exercise in vaulting and caping. The inclined plane, usually a deal plank, between 20 and these in length and 2 feet in breadth, sused for a variety of exercises, tending to strengthen the hands, arms, chest, aldomen, legs, and feet. The flying-course, or giant's stride, is an amusing exercise, but is not superior to any of the others in its effects. Then national games of England by themselves contain nearly all the advantages to be got by gymnastic exercise. These games, although not all, perhaps, originally belonging to this country, have been adopted, and have become peculiarly national through their oppularity and regular improvement. Wrestling, a sused for a variety of exercises, tending to strengthen he hands, arms, chest, abdomen, legs, and feet. The flying-course, or giant's stride, is an amusing exercise, but is not superior to any of the others in its effects. The national games of England by themselves contain nearly all the advantages to be got by gymnastic sercise. These games, although not all, perhaps, perms are made into a distinct class (Gymnogens) in circles. These games, although not all, perhaps, sperms are made into a distinct class (Gymnogens) in circles are greatly and regular improvement. Wrestling, a Dicotyledones. (See Angiosperms.)

### Gymnosperms

thoroughly English athletic sport, is only known theoretically on the continent. Boxing, an exercise which brings every muscle into actions gives elasticity to the limbs, improves the play of the lungs, gives quickness of eye and accuracy in measuring distances, is a practice particularly belonging to this country. As a nation, also, our recorded feats in riding, walking, and running, may challenge all Europe. Archery, from a very early period, has been a favourite pastime in which the English have excelled. The game of cricket is essentially English, and other games, such as golf and the English have excelled. The game of cricket is essentially English, and other games, such as golf and curling, belong almost exclusively to Soctland. In all cases gymnastic exercises of every kind should be practised with caution and moderation. Although the dangers connected with the practice of gymnastics are often exaggerated, nevertheless muscles may become strained through excess, and ruptures and other serious accidents occur.—Ref. Capt. Chioseo's Gymnastics and Calisthenics; G. Roland's Gymnastics Walker's British Manly Exercises; and the Gymnastic Free Exercises of P. H. Ling, translated by M. Roth, M.D.

GYMNEMA, jim-ne'-mā (Gr. gumnos, naked; nema.

GTENEMA, jim-ne'-mā (Gr. gumnos, naked; nema, filament), in Bot., a gen. of the nat. ord. Asclepiadacca. The species Galactifera, a native of Ceylon, yields a nutritious milk, which is used as human food. It is

called, on this account, the cow-plant.

Caused, on this account, the cow-plant.

GYMNOGENS, juin-no-jens (Gr. gumnos, naked; gennao, I produce), a term applied in Lindley's Botany to
those plants which are distinguished by having the
seeds naked, or uninclosed by seed-vessels. The
plants included in this class have nearly an equal
relation to flowering and flowerless plants. They
agree with the former in habit, in the presence of
sexes, and in their vascular tissue being complete;
among the latter, some accord in habit with the former among the latter, some accord in habit with the ferns and club-mosses. So great is the resemblance between some club-mosses and certain conifers, that they can be distinguished by no other external character except their size. Gymnogens are known from most other vasculares by the vessels of their wood having large apparent perforations or discs; they do not, however, differ in growth from other exogens, but are essentially differ in growth from other exogens, out are essentially the same, deviating in no respect from the plan upon which exogenous plants increase. In the gymnogens there is an unmistakable transition from the highest form of organization to the lowest. They are essentially exogens in all that appertains to their organs of vegetation, but they are analogous to reptiles, in the chimal kingdom, inasmuch as their ove are fertilized by direct contact with the male principle. The Confers and Cycads are the most remarkable orders. That of the Conifers is connected with club-mosses by means of the extinct genus Lepidodendron, and their branches sometimes so closely resemble those of certain lycopods that no doubt can be left of their relation. Some cycads

that no doubt can be left of their relation. Some eyeads have the gyrate vernation of the leaves of true ferns along with the inflorescence of conifers. The natural orders of the gymnogens are,—the Cycadaceæ, the Pinaceæ, the Taxaceæ, and the Gnetaceæ.

GYMNOSOPHISTS, jim-nos'-o-fists (Gr. gwmns, naked, and sophistes, a wise man), the name given by the sucient Greeks to a sect of Indian philosophers who went about naked, or almost naked. They dwelt in the woods, living on the wild products of the earth, and had a great reputation for learning and wisdom. They spent their time in mystical contemplation, and practised the most rigorous ascellation. Their most prominent tenet was the doctrine of the immortality and transmigration of the soul, and they were remarkpromuent tenet was the doctrine of the immortality and transmigration of the soul, and they were remarkable for their great contempt of death. They despised bodily pain, and inured themselves to the greatest tortures without manifesting the least indications of suffering. They practised suicide by burning, and in this way Calanus sacrificed himself at Babylon before Alexander the Great.

### Gymnotus Electricus

GYMMOTUS ELECTRICUS. (See ELECTRICAL ERL.)
GYMMOTUS. (See GYMOSEMPILE.)
GYMMOTUS, jo-re'-shops (Gr., game, female; cikes, houss), in Bot. a term applied to the female or pistiline organs of a flowering plant taken collectively.
(See Previl.)

GYNOPHORE. (See RECEPTACLE.)

CTHOREMIUM, jin-on-te-me-um (Gr. gune, female; etemma, grown), in Bot., a column formed in the centre of a flower by the complete union of the upper parts of the stamens and the pistil. Examples are afforded by the orchis and birthwort. Flowers that show this

GYESTER, jip'-seer, a term derived from a corruption of the word Egyptiane, and applied to a wandering race of people, who are found distributed over many countries of Europe and Asia. They seem to have migrated into Europe from the East, at the beginning of the 15th century; and first appeared in Faris in 1427, representing themselves as Christian penitents, 1427, representing themselves as Christian penitents, driven out of Egypt by the Saracens. They were more than a hundred and twenty in number, and, according to a French writer, "They had their ears pierced from which depended a ring of silver; their hair was black and crispy, and their women filthy to a degree, and were sorceresses, who told fortunes." They and their people, who arrived in great numbers, obtained permission to remain in the kingdom; but after a short while or account of their illeges and depredetions. while, on account of their idleness and depredations, terrible laws were enacted, in order to suppress them and drive them from the country. The name of "Bohemians" was given to them by the French, probably because a large number of them had come into France through Bohemia. Many, in consequence of the severity shown towards them, ware duran body into through Bohemia. Many, in consequence of the severity shown towards them, were driven back into the woods and forests of the same country; others passed into Germany and Hungary; while bands of others swarmed over the Pyrenees, and poured down upon the plains of Spain. The names by which the gypaies are known, differ with the country in which they are found, although, with one or two exceptions, not materially. In Russia they are styled Zigani; in Turkey and Persia, Zingarri; and in Germany, Zigenner; all which words apparently spring from the same root, probably "Zincali," a term by which these people, and especially those of Spain, which these people, and especially those of Spain, cometimes designate themselves, and the meaning of which is supposed to be "the black men of Zend, or Ind." The Zigani are found in all parts of Russis, except in the government of St. Peteraburg, from which they have been banished. Their principle employment is trafficking in horses and curing the diseases of cattle. In Moscow, however, they have given no their wandering habits, and inhabit stately given up their wandering habits, and inhabit stately houses, and go abroad in elegant carriages, being be-hind the higher orders of the Russians neither in appearance nor mental acquirements. The females are celebrated for their vocal powers. The Czigamy, or Hungarian gypsies, live in rags and filth, but are nerry, and fond of music. They are addicted to horsedealing, and are tinkers and smiths in a small way; the women cell fortunes, and both sexes are incorrigible thieves. In Wallachia and Moldavia, they call them-selves Roumouni, and in all countries the gypsies style themselves, and the language which they speak, Romnemetives, and the language which they speak, Rommany. In the gypsy language, Rom means a husband, and Rommany the sect of the husbands. Although no country appears less adapted for this wandering life, which seems so natural to these people, than England, it is nevertheless true that they do exist here, and the covered cart and little tent of the Rommanny seldom remain more than a day or two in one place. When the gypsies first arrived in England, they were much persecuted. After a time their persecutors got weary of pursuing them, and at present they are con-sidered in some degree as a privileged people. Although their way of life is unlawful, it is connived at, the law of their way of life is unlawful, it is connived at, the law of England having discovered, by experience, that its utmost fury is inefficient to restrain them from their habits. The male gypsies in England are all dealers in horses, and sometimes employ their idle time in yielding the tin and copper utensils of the peasantry; the females tell fortenes. In all countries the gypsies are very handsome when young, but hideously ugly when they grow old. The climate of England is favour-

## Gyroscope

able to beauty, and in no land is the appearance gypsy so preposessing as in this country. The design of the Rommanny which they apock is thereoff pies, but mixed with English words. Debting in some has always been a profession of the gypsissing. I have and countries, and is especially the precince of the females. They are divided into chases or index in England, and the principal gypsy tribes now in existence are the Stanleys, whose haunt is the New Forcest; the Lovells, who are fond of London and its vicinity; the Coopers, who live round about Windsor; the Smiths, who have taken up their abode in East Angles, and the Hernes, who have appropriated the North of England, and Yorkshire in especial. able to beauty, and in no land is the appear England, and Yorkshire in especial.

GYPSOPRILA. (See CARYOPHYLIACER.)
GYPSUM, jip'-sum (Lat.), a term applied to smorphous sulphate of lime, from which plaster of Paris It is also found in crystals as selenits, in emitransparent masses as alabaster. It has is made. compact semitransparent masses as alabaster. compact semitransparent masses as alabaster. It has evidently been formed by the decomposition of the iron pyrites, giving rise to sulphuric said, which, uniting with the chalk, formed 'sulphate of lime. Plaster of Paris is made by heating gypsum to about 250° Tahr., and powdering the calcined mass. Gypsum is also used as a manure. The addition of 1 or 2 per cent. of many saits, such as alum, sulphate of potash, or borax, confers upon gypsum the property of setting slowly into a mass capable of receiving a very hich nolish into a mass capable of receiving a very high polish. When treated in this way, it is known as Keane's.

Martin's, and Keating's coment. A GYS-FALCON. (See GYB-FALCON.)
GYBOMANCY, jir'-o-min-see (Gr. guros, a circle, and manteia, a prophecy), is a kind of divination performed by a soothsayer, by means of a circle. The soothsayer usually describes a circle variously marked with lefters. usually describes a circle variously marked with letters, and then walks round it with various ceremonies, say-

ing magic words and making mysterious motions, the more effectually to deceive the uninitiated.

Gyrofunda, je-rofu-rā, in Bot., a gen. of lichens, several species of which possess nutritive properties, and are used as food in the arctic regions. They been denominated tripe de roche (rock-tripe). Franklin and his companions, in 1821, used them, and indeed owed their preservation, in a great measure, to the nutriment they afforded. The species *G. pustulata* is one of the lichens used in this country by the manu-

facturers of orchil and cudbear.

GYROSCOPE, ji'-ros-kope (vir. guros, & circle or ro-ation: skopeo, I perceive), an instrument which has recently attracted attention on account of its supposed capability of rendering visible the rotation of the on its axis. The apparatus was originally suggested by M. Foucault, tut has since been materially modified. The principle on which its action depends was discovered about 1750, by Frisi, and enunciated by him as the Composition of Rotary Motions; and the object of the instrument is to exhibit the real composition of rotations about different axes impressed at the same rotations about different axes impressed at the same time on the same body. Thus, when a body is rotating about an axis, if any force tends to make it rotate about another axis, it will not rotate about either the old or the new axis, but about an intermediate one. In 1851, Signor Antinori, director of the museum at Elegance fast branchit the subject of the greatest time. Florence, first brought the subject of the apparent dis-placement of the plane of vibration of the pendulum efore the Academicians del Cimento; and on the 3rd of February, in the same year, M. Foncault communicated his discovery to the Academy of Sciences at cated his discovery to the Academy or sciences are Paris, and experimentally proved the rotation of the earth by his well-known pendulum experiment and his gyroscope. In the first case, if a pendulum is supposed to be suspended over either pole of the earth, and set in oscillation, it is evident that a spectator carried round by the rotation of the earth would so pass alternately under the two ends of the arc of the vibrating pendulum, that its plane of scillation would appear to him to make a revolution from east to west in the same time as the earth revolves from west to cast. If, then, the pendulum be supposed to be similarly suspended over the equator, it is evident that no change in the plane of oscillation can take place. But if the pendulum is suspended at any intermediate latitude, the rotation of the earth round the polar axis may be considered as the resultant of two rotations, one round an axis passing through the place of observa-
